Richard Fletcher, the younger, of Cranbrook, Kent, and father of the poets Phineas and Giles Fletcher, was born in 1548 or 1549. He was educated at Eton and at King's College, Cambridge. He entered the Middle Temple in 1570. He was called to the bar in 1575 and was made LL.D. in 1581. In 1580 he had married Joan Sheafe of Cranbrook. In that year he was commissioned to Dr. Bridgewater, chancellor of Ely, and in 1585 he sat in parliament for Winchelsea. He was employed on diplomatic service in Scotland, Germany and Holland, and in 1588 was sent to Russia to the court of the czar Theodore with instructions to conclude an alliance between England and Russia, to restore English trade, and to obtain better conditions for the English Russia Company. The factor of the company, Jerome Horsey, had already obtained large concessions through the favour of the protector, Boris Godunov, but when Dr. Fletcher reached Moscow in 1588 he found that Godunov's interest was alienated, and that the Russian government was contemplating an alliance with Spain. The envoy was badly lodged, and treated with obvious contempt, and was not allowed to forward letters to England, but the English victory over the Armada and his own indisputable patience secured among other advantages for English traders exclusive rights of trading on the Volga and their security from the infliction of torture. Fletcher's treatment at Moscow was later made the subject of formal complaint by Queen Elizabeth. He returned to England in 1589 in company with Jerome Horsey, and in 1591 he published Of the Russie Commonwealth, Or Moner of Government by the Russie Emporour (commonly called The Emporour of Moscova) with the manners and fashions of the people of that Country. In this comprehensive account of Russian geography, government, law, methods of warfare, church and manners, Fletcher, who states that he began to arrange his material during the return journey, doubtless received some assistance from the longer experience of his travelling companion, who also wrote a narrative of his travels, published in Puchas his Pilgrimes (1606). The Russia Company feared that the freedom of Fletcher's criticisms would give offence to the Muscovite authorities, and accordingly damage their trade. The book was consequently suppressed, and was not reprinted in its entirety until 1836, when it was edited from a copy of the original edition for the Hakluyt Society, with an introduction by Lord Astor. In 1610, when the company of which Fletcher was appointed "Remembrancer" to the city of London, and an extraordinary master of requests in 1596, and became treasurer of St. Paul's in 1597. He contemplated a history of the reign of Queen Elizabeth, and in a letter to Lord Burghley he suggested that it might be well to begin with an account from the Protestant side of the marriage of Henry VIII. and Ann Boleyn. But personal difficulties prevented the execution of this plan. He had become security to the exchequer for the debts of his brother, Richard Fletcher, bishop of London, who died in 1596, and was only then saved from imprisonment by the protection of the earl of Essex. He was actually in prison in 1601, when he addressed a somewhat ambiguous letter to Burghley from which it may be gathered that his prime offence had been an allusion to Essex's disgrace as being the work of Sir Walter Raleigh. Fletcher was employed in 1610 to negotiate with Denmark on behalf of the "Eastland Merchants," and he died next year, and was buried on the 11th of March in the parish of St. Catherine Colman, London.

The Russie Commonwealth was issued in an abridged form in Hakluyt's Principal Navigations, Voyages, etc. (vol. i. p. 475, ed. 1616), a somewhat complete version in Puchas his Pilgrimes (pt. iii. ed. 1625), also as History of Russia in 1643 and 1657.
FLETCHER, John William (1749-1782), English divine, was born at Nyon in Switzerland on the 12th of September 1749, his original name being de la Fécétière. He was educated at Geneva, but preferred an army career to a clerical one, went to Lisbon and enlisted. An accident brought on his sailing with his regiment to Brazil, and after a visit to Flanders, where an uncle offered to secure a commission for him, he went to England, picked up the language, and in 1752 became tutor in a Shropshire family. Here he came under the influence of the new Methodist preachers, and in 1757 took orders, being ordained by the bishop of Bangor. He often preached with John Wesley and for him, and became known as a fervent supporter of the revival. Refusing the wealthy living of Dunham, he accepted the humble duties of the curacy of Stockport for twenty-five years (1760-1785) he lived and worked with unique devotion and zeal. Fletcher was one of the few parish clergy who understood Wesley and his work, yet he never wrote or said anything inconsistent with his own Anglican position. In theology he upheld the Arminian against the Calvinist position, but always with courtesy and fairness; his resignation on doctrinal grounds of the superintendency (1766-1771) of the county of Huntingdon and its church at Trecceva left unpleasantsness. The outstanding feature of his life was a transparent simplicity and saintliness of thankfulness. He lived in the last stages of his life with his godliness is unanimous. Wesley preached his funeral sermon from the words "Mark the perfect man". Southey said that "no age ever provided a man of more fervent piety or more perfect charity, and no church ever possessed a more apostolic minister."

Fletcher's name was not confined to his own country, for it is said that Voltaire, when challenged to produce a character as perfect as that of Christ, at once mentioned Fletcher of Madeley. He died on the 14th of August 1785.

Complete editions of his works were published in 1803 and 1836. The chief of them, written against Calvinism, are Five Checks to Antinomianism, Scripture Scales to weigh the Gold of Gospel Truth, and the Portrait of St Paul. See lives by J. Wesley (1786); L. Rymer (1828); F. W. Macdonald (1851); J. Marat (1852); C. J. Ryle, Christian Leaders of the 18th Century, pp. 384-423 (1869).

FLETCHER, Phineas (1582-1650). English poet, elder son of Dr Giles Fletcher, and brother of Giles the younger, noticed above, was born at Cranbrook, Kent, and was baptized on the 8th of April 1582. He was admitted a scholar of Eton, and in 1600 entered King's College, Cambridge. He graduated B.A. in 1603, and M.A. in 1606, and was one of the contributors to the Works of John Fletcher (1607) and the World's Poets (1604). His pastoral drama, Sicelides or Piscatory (1613) was written (1614) for performance before James I., but only produced after the king's departure at King's College.

FLETCHER, Giles-Fletcher, P. (1584-1623), English poet, younger son of the preceding, was born about 1584. Fuller in his Works of England says that he was a native of London, and was educated at Westminster school. From there he went to Trinity College, Cambridge, where he took his B.A. degree in 1608, and became a minor fellow of his college in 1608. He was a fellow in Greek grammar, 1615, and to the Greek language he contributed a poem on the death of Queen Elizabeth to Sorrow's Joy. His great poem of Christ's Victory appeared in 1610, and in 1612 he edited the Remains of his cousin Nathaniel Pownall. It is not known in what year he was ordained, but his sermons at St Mary's were famous. Fuller tells us that the prayer before the sermon was a continuous allegory. He left Cambridge about 1618, and soon after received, it is supposed from Francis Bacon, the rectorcy of Alderton, on the Suffolk coast, where "his clownish and low-parted parishioners ... valued not their pastor according to his worth, which disposed him to melancholy and hastened his dissolution." (Fuller, Worthies of England, ed. 1811, vol. ii. p. 82.) His last work, The Reward of the Faithful, appeared in the year of his death (1623).

The principal work by which Giles Fletcher is known is Christ's Victory and Triumph, in Heaven, in Earth, and after Death (1610). An edition in 1649 contains seven full-page illustrative engravings by George Tate. It is in four cantos and is epic in design. The first canto, "Christ's Victory in Heaven," represents a dispute in heaven between Justice and Mankind, in which Mankind is defeated, and Christ forever reigns there. The second canto, "Christ's Victory on Earth," deals with an allegorical account of the Temptation; the third, "Christ's Triumph over Death," treats of the Passion; and the fourth, "Christ's Triumph after Death," treating of the Resurrection and Ascension, concludes with an affecionate eulogy of his brother Phineas Fletcher (q.v.) as "Thyrisil." The metre is an eight-line stanza owing something to Spenser. The first five lines rhyme abbd, and the stanza concludes with a rhyming triplet, resuming the conceit which nearly every verse embodies. Giles Fletcher, like his brother Phineas, to whom he was deeply attached, was a close follower of Spenser. In his very best passages Giles Fletcher attains to a rich melody which charmed the ear of Milton, who did not hesitate to borrow very considerably from the Christ's Victory and Triumph in his Paradise Regained. Fletcher lived in an age which regarded as models the poems of Marini and Gongora, and his conceits are sometimes grotesque in connexion with the sacredness of his subject. But when he is carried away by his theme and forgets to be ingenious, he attains great solemnity and harmony of style. His descriptions of the Lady of the Tides, and of the Land of Judgment, and of the Land of Joy, and of Mercy in the first, are worked out with much beauty of detail into separate pictures, in the manner of the Faerie Queene.

Giles Fletcher's poem was edited (1668) by the Fullers Worthies Library, and (1876) for the Early English Poets by Dr A. B. Grosart. It is also reprinted for The Ancient and Modern Library of Theology and Literature by J. G. Leland in Ritson's and Ritson's and Ritson's Sacred Classics (1834, 42, etc.) vol. 20. In the library of King's College, Cambridge, is a MS. Aegidii Fletcheri versio poetica Lamentationum Jeremiae.
aim to lose himself in digressions like those of the Faerie Queen. What he gains in unity of design, however, he more than loses in human interest and action. The chief charm of the poem lies in its descriptions of rural scenery. The Piscatory Etogues are pastorals the characters of which are represented by noble boys on the banks of the Cam, and are interesting for the light they cast on the biography of the poet himself (Thysyll) and his father (Thelgon). The poetry of Phineas Fletcher has not the subtlety sometimes reached by his brother Giles. The mannerisms are more pronounced and the conceits more far-fetched, but the verse is fluent, and lacks neither colour nor music.

A complete edition of his works (4 vols.) was privately printed by Dr A. B. Grosart (Fuller Worthies Library, 1869).

FLEURANGES, ROBERT (III.) DE LA MARCK, SEIGNEUR (1491-1537), marshal of France and historian, was the son of Robert II. de la Marck, duke of Bouillon, seigneur of Sedan and Fleurenges, whose uncle was the celebrated William de la Marck, "The Wild Boar of the Ardennes." A fondness for military exercises displayed itself in his earliest years, and at the age of ten he was sent to the court of Louis XII., and placed in charge of the count of Angoulême, afterwards King Francis I. In his twentieth year he married a niece of the cardinal d'Amboise, but after three months he quitted his home to join the French army in the Milanese. With a handful of troops he threw himself into Verona, then besieged by the Venetians; but the siege was protracted, and being impatient for more active service, he rejoined the army. He then took part in the relief of Mirandola, besieged by the troops of Pope Julius II., and in other actions of the campaign. In 1512 the French being driven from Italy, Fleurenges was sent into Flanders to levy a body of 10,000 men, in command of which, under his father, he returned to Italy in 1513, seized Alessandria, and vigorously assailed Novara. But the French were defeated, and Fleurenges narrowly escaped with his life, having received more than forty wounds. He was rescued by his father and sent to Vercelli, and thence to Lyons. Returning to Italy with Francis I. in 1515, he distinguished himself in various affairs, and especially at Marignano, where he had a horse shot under him, and contributed so powerfully to the victory of the French that the king knighted him with his own hand. He next took Cremona, and was there called home by the news of his father's illness. In 1519 he was sent into Germany on the difficult errand of inducing the electors to give their votes in favour of Francis I.; but in this he failed. The war in Italy being rekindled, Fleurenges accompanied the king thither, fought at Pavia (1525), and was taken prisoner with his royal master. The emperor, irritated by the conduct of his father, Robert II. de la Marck, sent him into confinement in Florence, where he remained for some years. During this imprisonment he was created marshal of France. He employed his enforced leisure in writing his Histoire des choses memorable des advenues du royaume de Louis XII et de Francois I, depuis 1490 jusqu'en l'an 1531. In this work he designates himself Jeune Advenolors. Within a small compass he gives many curious and interesting details of the time, writing only of what he had seen, and in a very simple but vivid style. The book was first published in 1735, by Abbé Lambert, with added historical and critical notes; and it has been reprinted in several collections. The last occasion on which Fleurenges was engaged in active service was at the defence of Péronne, besieged by the count of Nassau in 1536. In the following year he heard of his father's death, and set out from Amboise for his estate of La Marck; but he was seized with illness at Longjumeau, and died there in December 1537.

FLEUR-DE-LIS (Fr. "lily flower"), an heraldic device, very widespread in the armorial bearings of all countries, but more particularly associated with the royal house of France. The conventional fleur-de-lis, as Litré says, represents very imperfectly three flowers of the white lily (Lilium) joined together, the central one erect, and each of the other two curving outwards. The fleur-de-lis is a common device in ancient decoration, notably in India and in Egypt, where it was the symbol of life and resurrection, the attribute of the god Horus. It is common also in Etruscan bronzes. It is uncertain whether the conventional fleur-de-lis was originally meant to represent the lily or white iris—the flower-de-lice of Shakespeare—or an arrow-head, a spear-head, an amulet fastened on date-palms to ward off the evil eye, &c. In Roman and early Gothic architecture the fleur-de-lis is a frequent sculptured ornament. As early as 1170 three fleurs-de-lis were sculptured on the capitals of the Chapelle St-Aignan at Paris. The fleur-de-lis was first definitely connected with the French monarchy in an ordonnance of Louis le Jeune (c. 1147), and was afterwards adopted by Philip Augustus in 1280. The use of the fleur-de-lis in heraldry dates from the 12th century, soon after which period it became a very common charge in France, England and Germany, where every gentleman of coat-armour desired to adorn his shield with a loan from the shield of France, which was at first d'azur, semé de fleurs de lis d'or. In February 1376 Charles V. of France reduced the number of fleurs-de-lis to three—in honour of the Trinity—and the kings of France thereafter bore d'azur, à trois fleurs de lis d'or. Tradition soon attributed the origin of the fleur-de-lis to Clavis, the founder of the Frankish monarchy, and explained that it represented the lily given to him by an angel at his baptism. Probably there was as much foundation for this legend as for the more rationalistic explanation of William Newton (Display of Heraldry, p. 145), that the fleur-de-lis was the figure of a reed or flag in blossom, used instead of a sceptre at the proclamation of the Frankish kings. Whatever be the true origin of the fleur-de-lis as a conventional decoration, it is demonstrably far older than the Frankish monarchy, and history does not record the reason of its adoption by the royal house of France, from which it passed into common use as an heraldic charge in most European countries. An order of the Lily, with a fleur-de-lis for badge, was established in the Roman states by Pope Paul III. in 1546; its members were pledged to defend the patrimony of St Peter against the enemies of the church. Another order of the Lily was founded by Louis XVIII. in 1816, in memory of the silver fleurs-de-lis which the comte d'Artois had given to the troops in 1874 as decorations; it was abolished by the revolution of 1830.

FLEURUS, a village of Belgium, in the province of Hennegau, 5 m. N.E. of Charleroi, famous as the scene of several battles. The first of these was fought on August 19/20, 1622, between the forces of Count Mansfeld and Christian of Brunswick and the Spaniards under Cordovas, the latter being defeated. The second is described below, and the third and fourth, incidents of Jourdan's campaign of 1794, under French Revolutionary Wars. The ground immediately north-east of Fleurus forms the battlefield of Ligny (June 16, 1815), for which see Waterloo Campaign.

The second battle was fought on the 1st of July 1690 between 45,000 French under François-Henri de Montgomery-Bouteville, duke of Luxemburg, and 37,000 allied Dutch, Spaniards and Imperialists under George Frederick, prince of Waldeck. The latter had formed up his army between Heppignies and St Amand in what was then considered an ideal position; a double barrier of marshy brooks was in front, each flank resting on a village, and the space between, open upland, fitted for cavalry exactly. But Luxemburg, riding up with his advanced guard from Velaine, decided, after a cursory survey of the ground, to
attack the front and both flanks of the Allies’ position at once—a decision which few, if any, generals then living would have dared to make, and which of itself places Luxemburg in the same rank as a tactician as his old friend and commander Condé. The left wing of cavalry was to move under cover of woods, houses, and hollows to gain Wagenées, where it was to connect with the frontal attack of the French centre from Fleurus and to envelop Waldeck’s right. Luxemburg himself with the right wing of cavalry and some infantry and artillery made a wise sweep round the enemy’s left by way of Ligny and Les Trois Burettes, concealed by the high-standing corn. At 8 o’clock the frontal attack began by a vigorous artillery engagement, in which the French, though greatly outnumbered in guns, held their own, and three hours later Waldeck, whose attention had been absorbed by events on the front, found a long line of the enemy already formed up in his rear. He at once brought his second line back to oppose them, but while he was doing so the French leader filled up the gap between himself and the frontal assailants by posting infantry around Wagenées, and also guns on the neighbouring hill whence their fire enfiladed both halves of the enemy’s army up to the limit of their ranging power. At 1 p.m. Luxemburg ordered a general attack of his whole line. He himself scattered the cavalry opposed to him and hustled the Dutch infantry into St Amand, where they were promptly surrounded. The left and centre of the French army were less fortunate, and in their first charge lost their leader, Lieutenant-General Jean Christophe, comte de Gournay, one of the best cavalry officers in the service. But Waldeck, hoping to profit by this momentary success, sent a portion of his right wing towards St Amand, where it merely shared the fate of his left, and the day was decided. Only a quarter of the cavalry and 14 battalions of infantry (English and Dutch) remained intact, and Waldeck could do no more, but with these he emulated the last stand of the Spaniards at Rocroi fifty years before. A great square was formed of the infantry, and a handful of cavalry joined them—the French cavalry, eager to avenge Gournay, had swept away the rest. Then slowly and in perfect order, they retired into the broken ground above Mellet, where they were in safety. The French slept on the battlefield, and then returned to camp with their trophies and 8000 prisoners. They had lost some 2500 killed, amongst them Gournay and Berbier du Metz, the chief of artillery, the Allies twice as many, as well as 48 guns, and Luxemburg was able to send 150 colours and standards to decorate Notre-Dame. But the victory was not followed up, for Louis XIV. ordered Luxemburg to keep in line with other French armies which were carrying on more or less desultory wars of manoeuvre on the Meuse and Moselle.

FLEURY [ABRAHAM JOSEPH BÉNARD] (1750–1822), French actor, was born at Chartres on the 26th of October 1750, and began his stage apprenticeship at Nancy, where his father was a sub-dean of a community of Augustinians attached to the court of King Stanislaus. After four years in the provinces, he came to Paris in 1778, and almost immediately was made sociétair at the Comédie Française, although the public was slow to recognize him as the greatest comedian of his time. In 1793 Fleury, like the rest of his fellow-players, was arrested in consequence of the presentation of Laya’s L’Ami des lois, and, when liberated, appeared at various theatres until, in 1799, he rejoined the rehabilitated Comédie Française. After forty years of service he retired in 1818, and died on the 3rd of March 1822. He was the most illustrious of a long line of actors, and it is probable that the interesting Mémoire de Fleury owes more to its author, Lafitte, than to the subject whose “notes and papers” it is said to contain.

FLEURY, ANDRÉ HERCULE DE (1663–1743), French cardinal and statesman, was born at Lodève (Hérault) on the 22nd of June 1663, the son of a collector of taxes. Educated by the Jesuits in Paris, he entered the priesthood, and became in 1679, through the influence of Cardinal Bonzi, almoner to Maria Theresa, queen of Louis XIV., and in 1698 bishop of Préjus. Seventeen years of a country bishopric determined him to seek a position at court. He became tutor to the king’s grandson, and by his own spinet and the grace of his racy ambition, he acquired over the child’s mind an influence which proved to be indestructible. On the death of the regent Orleans in 1723 Fleury, although already seventy years of age, deferred his own supremacy by suggesting the appointment of Louis Henri, duke of Bourbon, as first minister. Fleury was present at all interviews between Louis XV. and his first minister, and on Bourbon’s attempt to break through this rule Fleury retired from court. Louis made Bourbon recall the tutor, who on the 11th of July 1726 took affairs into his own hands, and secured the exile from court of Bourbon and of his mistress Madame de Prie. He refused the title of first minister, but his elevation to the cardinalate in that year secured his precedence over the other ministers. He was naturally frugal and prudent, and carried these qualities into the administration, with the result that in 1738–1739 there was a surplus of 15,000,000 livres instead of the usual deficit. In 1726 he fixed the standard of the currency and secured the credit of the government by the regular payment thenceforward of the interest on the debt. By exacting forced labour from the peasants he gave France admirable roads, though at the cost of raising angry discontent. During the seventeen years Fleury was at the head of the French government he was able to recapture its forces after the exhaustion caused by the extravagances of Louis XIV. and of the regent, and the general prosperity rapidly increased. Internal peace was only seriously disturbed by the severities which Fleury saw fit to exercise against the Jansenists. He imprisoned priests who refused to accept the bull Unigenitus, and he met the opposition of the parlement of Paris by exiling forty of its members.

In foreign affairs his chief preoccupation was the maintenance of peace, which was shared by Sir Robert Walpole, and therefore there was a general understanding between France and England. It was only with reluctance that he supported the ambitious projects of Elizabeth Farnese, queen of Spain, in Italy by guaranteeing in 1729 the succession of Don Carlos to the duchies of Parma and Tuscany. Fleury had economized in the army and navy, as elsewhere, and when in 1733 war was forced upon him he was hardly prepared. He was compelled by public opinion to support the claims of Louis XV.’s father-in-law Stanislaus Leszczynski, ex-king of Poland, to the Polish crown on the death of Frederick Augustus I., against the Russian-Austrian candidate; but the desperate nature of a French expedition of 1500 men to Danzig only served to humiliate France. Fleury was driven by Chauvelin to more energetic measures; he concluded a close alliance with the Spanish Bourbons and sent two armies against the Austrians. Military successes on the
Rhine and in Italy secured the favourable terms of the treaty of Vienna (1735-1736). France had joined with the other powers in guaranteeing the succession of Maria Theresa under the Pragmatic Sanction, but on the death of Charles VI. in 1740 Fleury by a diplomatic quibble found an excuse for repudiating his engagements, when he found the party of war supreme in the king's councils. After the disasters of the Bohemian campaign he wrote in confidence a humble letter to the Austrian general Königsegg, who immediately published it. Fleury disavowed his own letter, and died a few days after the French evacuation of Prague on the 20th of January 1743. He had endowed the library by many valuable oriental MSS., and was a member of the French Academy, of the Academy of Science, and of the Academy of Inscriptions.

FLEURY, CLAUDE (1680-1723). French ecclesiastical historian, was born at Paris on the 6th of December 1680. Destined for the bar, he was educated at the aristocratic College of Clermont (now that of Louis-le-Grand). In 1698 he was nominated an advocate to the parlement of Paris, and for nine years followed the legal profession. But he had long been of a religious disposition, and in 1677 turned from law to theology. He had been some time in orders when Louis XIV., in 1672, selected him as tutor of the princes of Conti, with such success that the king next entrusted to him the education of the count of Vermandois, one of his natural sons, on whose death in 1683 Fleury received for it a pension of an abbey of Loc-Dieu, in the diocese of Rhodose. In 1689 he was appointed sub-preceptor of the dukes of Burgundy, of Anjou, and of Berry, and thus became intimately associated with Fénelon, his chief tutor. In 1696 he was elected to fill the place of La Bruyère in the French Academy; and on the completion of the education of the young princes the king bestowed upon him the rich priory of Argenteuil, in the diocese of Paris (1706). On assuming this benefice he resigned, with rare disinterestedness, that of the abbey of Loc-Dieu. About this time he began his great work, the first of the kind in France, a history of the church of Loc-Dieu, to which he had been collecting materials for thirty years—the Histoire écclésiastique. Fleury's evident intention was to write a history of the church for all classes of society; but at the time in which his great work appeared it was less religion than theology that absorbed the attention of the clergy and the educated public; and his work accordingly appealed to the student rather than to the popular reader, dwelling as it does very particularly on questions of doctrine, of discipline, of supremacy, and of rivalry between the priest- hood and the imperial power. Nevertheless it had a great success.

The first edition, printed at Paris in 20 volumes 4to, 1691, was followed by many others, among which may be mentioned that of Brussels, in 32 vols. 8vo, 1692, and that of Nismes, in 18 vols. 8vo, 1778 to 1780. The work of Fleury only comes down to the year 1714. It was continued by J. Claude Fabre and Gujeot down to 1795, in 16 vols. 4to. In consulting the work of Fleury and its supplement, the general table of contents, published by Rondel, Paris, 1738, 1 vol. 4to, will be found very useful. Translations have been made of the first three books of the German and Italian. The Latin translation, published at Augsburg, 1758-1790, 85 vols. 8vo, carries the work down to 1684.

Fleury, who had been appointed confessor to the young king Louis XV. in 1716, because, as the duke of Orleans said, he was neither Jansenist nor Molinist, nor Ultramontanist, but Catholic, died on the 14th of July 1723. His great learning was equalled by the modest simplicity of his life and the uprightness of his conduct.

Fleury left many works besides his Histoire ecclésiastique. The following deserve special mention:—Histoire du droit français (1674, 12 vols); Mœurs des Israélites (1681, 12 vols); Mœurs des Chrétiens (1690, 12 vols); Traité du choix et de la méthode des études (1686, 2 vols. 12mo); Les Désirs des maîtres et des domestiques (1687, 12 vols.); A number of the smaller works were published in one volume at Paris in 1707. The Roman Congregation of the Index condemned Fleury's Historien ecclésiastique (1695) and the Institution du droit ecclésiastique (1697).

Fleury, considéré comme historien de l'église (Strassburg, 1847, 8vo); Reichlin-Meldegg, Geschichte des Christentums, i.

FLEURY, THEODOR (1800-1864), German Protestant divine, was born on the 21st of January 1800 at Epstein (near Wiesbaden), the small village in which his father was pastor. He studied theology at the universities of Giessen and Göttingen, and at the theological seminary of Herborn, and at the age of twenty he passed his final examination. After a year spent in teaching and preaching, in 1821 he accepted a call from the Protestant church at Kaiserswerth, a little town on the Rhine, a few miles below Düsseldorf. To help his people and to provide an endowment for his church, he undertook journeys in 1822 through part of Germany, and then in 1823 to Holland and England. He met with considerable success, and had opportunities of observing what was being done towards prison reform; in England he made the acquaintance of philanthropists and religious reformers. He was appointed superintendent of the poor in the Rhineland (1823-1830), and was visitant in the prison of Düsseldorf (1825-1826), and inspector of the first Prinzen Society of Germany (Rheinisch-Westfälischer Gefängnisverein) was founded. In 1833 Fleiderer opened his own orphanage garden at Kaiserswerth a refuge for discharged female convicts. His circle of practical philanthropy rapidly increased. The state of the sick poor had for some time excited his interest, and it seemed to him that hospitals might be best served by an organized body of specially trained women. Accordingly in 1836 he began the first deaconess house, and the hospital at Kaiserswerth. By their ordinance the deaconesses devoted themselves to the care of the poor, the sick and the young; but their engagements were not final—they might leave their work and return to ordinary life if they chose. In addition to these institutions Fleiderer founded in 1835 an infant school, then a normal school for infant school mistresses (1836), an orphanage for orphan girls of the middle class (1842), and an asylum for female lunatics (1847). Moreover, he assisted at the foundation and in the management of similar institutions, not only in Germany, but in various parts of Europe.

In 1849 he resigned his pastorial charge, and from 1849 to 1851 he travelled over a large part of Europe, America and the East—the object of his journeys being to find "mother houses," which were to be not merely training schools for deaconesses, but also centres whence other training establishments might arise. He established a deaconess house in Jerusalem, and after his return assisted by counsel and money in the erection of establishments at Constantinople, Smyrna, Alexandria and Bucharest. Among his later efforts may be mentioned the Christian house of refuge for female servants in Berlin (connected with which other institutions soon arose) and the "house of evening rest" for retired deaconesses at Kaiserswerth. In 1855 Fleiderer received the degree of doctor in theology from the university of Bonn, in recognition rather of his practical activity than of his theological attainments. He died on the 4th of October 1864, leaving behind him over 100 stations attended by 430 deaconesses; and these boards had increased to 123 with an attendance of 600.

Fleiden's son was Franz Fleiderer (1824-1885), who, after studying in Halle and Tubingen, became in 1858 chaplain to the embassy in
Madrid. He followed in his father's footsteps by founding several philanthropic institutions in Spain. He was also the author of a number of books, amongst which was an autobiography, *Aus meinem Leben. Erinnerungen und Erfahrungen* (1901).

Theodor Fliedner's writings are almost entirely of a practical character. He edited a periodical, *Der Arzt und Kranken Freund* which contained information regarding the various institutions, and also the yearly almanac of the Kaiserswerth Institution. Besides purely educational and devotional works, he wrote *Buch der Martyrer* (1852); *Kurze Geschichte der Entstehung der ersten engl. Liebesanstalten zu Kaiserswerth* (1856); *Nachricht über das Diakonissen-Werk in der Christ. Kirche* (5th ed., 1867); *Die evangel. Martyrer Ungarns und Serbiens. Ein Reisetagebuch der Reise nach Jerusalem und Constantinopel* All were published at Kaiserswerth. There is a translation of the German life by C. Winkworth (London, 1867).

**FLIGHT and FLYING.** Of the many scientific problems of modern times, there are few possessing a wider or more enduring interest than that of aerial navigation (see also AERONAUTICS). To fly has always been an object of ambition with man; nor will this occasion surprise when we remember the marvellous freedom enjoyed by volant as compared with non-volant animals. The subject of aviation is admittedly one of extreme difficulty. To tread upon the air (and this is what is really meant) is, at first sight, in the highest degree Utopian; and yet there are thousands of living creatures which actually accomplish this feat. These creatures, however varied in form and structure, all fly according to one and the same principle; and this is a significant fact, as it tends to show that the air must be attacked in a particular way to ensure flight. It behoves us then at the outset to scrutinize very carefully the general configuration of flying animals, and in particular the size, shape and movements of their flying organs.

Flying animals differ entirely from sailing ships and from balloons, with which they are not unfrequently though erroneously compared; and a flying machine constructed upon proper principles can have nothing in common with either of those creations. The ship floats upon water and the balloon upon air; but the ship differs from the balloon, and the ship and the balloon differ from the flying creature and flying machine. The water and air, moreover, have characteristics of their own. The analogies which connect the water with the air, the ship with the balloon, and the ship and the balloon with the flying creature and flying machine are false analogies. A sailing ship is supported by the water and requires merely to be propelled; a flying creature and a flying machine constructed on the living type require to be both supported and propelled. This arises from the fact that water is much denser than air, and because water supports on its surface substances which fall through air. While water and air are both fluid media, they are to be distinguished from each other in the following particulars. Water is comparatively very heavy, inelastic and incompressible; air, on the other hand, is comparatively very light, elastic and compressible. If water be struck with violence, the recoil occurs, but is not so great when compared with the recoil obtained from air similarly treated. In water we get a maximum recoil with a minimum of displacement; in air, on the contrary, we obtain a minimum recoil with a maximum of displacement. Water and air when unconfined yield readily to pressure. They thus form *movable fulera* to bodies acting upon them. In order to meet these peculiarities the travelling organs of aquatic and flying animals (whether they be feet, fins, flippers or wings) are made not of rigid but of elastic materials. The travelling organs, moreover, increase in size in proportion to the tenacity of the fluid to be acted upon. The difference in size of the travelling organs of animals becomes very marked when the land animals are contrasted with the aquatic, and the aquatic with the aerial, as in figs. 1, 2 and 3.

The peculiarities of water and air as supporting media are well illustrated by a reference to swimming, diving and flying birds. A bird when swimming extends its feet simultaneously or alternately in a backward direction, and so obtains a forward recoil. The water supports the bird, and the feet simply propel. In this case the bird is lighter than the water, and the long axis of the body is horizontal (a of fig. 4). When the bird dives, or flies under water, the long axis of the body is inclined obliquely downwards and forwards, and the bird forces itself into and beneath the water by the action of its feet, or wings, or both. In diving or sub-aquatic flight the feet strike upwards and backwards, the wings downwards and backwards (b of fig. 4). In aerial flying everything is reversed. The long axis of the bird is inclined obliquely upwards and forwards, and the wings strike, not downwards and backwards, but downwards and forwards (c of fig. 4). These changes in the direction of the long axis of the bird in swimming, diving and flying, and in the direction of the stroke of the wings in sub-aquatic and aerial flight, are due to the fact that the bird is heavier than the air and lighter than the water.

The physical properties of water and air explain in a great measure how the sailing ship differs from the balloon, and how the latter differs from the flying creature and flying machine constructed on the natural type. The sailing ship is, as it were, immersed in two oceans, viz. an ocean of water and an ocean of air—the former being greatly heavier and denser than the latter. The ocean of water buoyos or floats the ship, and the ocean of air, or part of it in motion, swells the sails which propel the ship. The moving air, which strikes the sails directly, strikes the hull of the vessel indirectly and forces it through the water, which, as explained, is a comparatively dense fluid. When the
ship is in motion it can be steered either by the sails alone, or by the rudder alone, or by both combined. A balloon differs from a sailing ship in being immersed in only one ocean, viz. the ocean of air. It resembles the ship in floating upon the air, as the ship floats upon the water; in other words, the balloon is lighter than the air, as the ship is lighter than the water. But here all analogy ceases. The ship, in virtue of its being immersed in two fluids having different densities, can be steered and made to tack about in a horizontal plane in any given direction. This in the case of the balloon, immersed in one fluid, is impossible. The balloon in a calm can only rise and fall in a vertical line. Its horizontal movements, which ought to be the more important, are accidental movements due to air currents, and cannot be controlled; the balloon, in short, cannot be guided. One might as well attempt to steer a boat carried along by currents of water in the absence of oars, sails and wind, as to steer a balloon carried along by currents of air. The balloon has no hold upon the air, and this consequently cannot be employed as a fulcrum for regulating its course. The balloon, because of its vast size and from its being lighter than the air, is completely at the mercy of the wind. It forms an integral part, so to speak, of the wind for the time being, and the direction of the wind in every instance determines the horizontal motion of the balloon. The force required to propel a balloon against even a moderate breeze would result in its destruction. The balloon cannot be transferred with any degree of certainty from one point of the earth's surface to another, and hence the chief danger in its employment. It may, quite as likely as not, carry its occupants out to sea. The balloon is a mere lifting machine and is in no sense to be regarded as a flying machine. It resembles the flying creature only in this, that it is immersed in the ocean of air in which it sustains itself. The mode of suspension is wholly different. The balloon floats because it is lighter than the air; the flying creature floats because it extracts from the air, by the vigorous downward action of its wings, a certain amount of upward recoil. The balloon is passive; the flying creature is active. The balloon is controlled by the wind; the flying creature controls the wind. The balloon in the absence of wind can only rise and fall in a vertical line; the flying creature can fly in a horizontal plane in any given direction. The balloon is inefficient because of its levity; the flying creature is efficient because of its weight.

Weight, however paradoxical it may appear, is necessary to flight. Everything which flies is vastly heavier than the air. The inertia of the mass of the flying creature enables it to control and direct its movements in the air. Many are of opinion that flight is a mere matter of levity and power. This is quite a mis-

lighter than the water might swim, and that a bird lighter than the air might fly: it ought, however, to be borne in mind that, in point of fact, a fish lighter than the water could not hold its own if the water were in the least perturbed, and that a bird lighter than the air would be swept into space by even a moderate breeze.
breeze without hope of return. Weight and power are always associated in living animals, and the fact that living animals are made heavier than the medium they are to navigate may be regarded as a conclusive argument in favour of weight being necessary alike to the fish and the flying animal. The cause, however, in the case of the fish and the flying animal, is different. It may be stated once for all that all flying creatures are for the most part as heavy, bulk for bulk, as other animals, and that flight in every instance is the product, not of superior lift, but of weight and power directed upon properly constructed flying organs.

This fact is important as bearing on the construction of flying machines. It shows that a flying machine need not necessarily be a light, airy structure exposing an immoderate amount of surface. On the contrary, it favours the belief that it should be a compact and moderately heavy and powerful structure, which trusts for elevation and propulsion entirely to its flying appliances—whether actively moving wings, or screws, or aeroplanes wedged forward by screws. It should attack and subdue the air, and never give the air an opportunity of attacking or subduing it. It should smite the air intelligently and as a master, and its vigorous well-directed thrusts should in every instance elicit an upward and forward recoil. The flying machine must be 

\[ \textit{mutilum in parto}. \]

It must launch itself in the ocean of air, and must extract from that air, by means of its travelling surfaces, the power necessary to overcome the force of gravity and thus make the aerial voyage possible. The flying machine which could not face air currents would necessarily be a failure. To obviate this difficulty we are forced to fall back upon weight, or rather the structures and appliances which weight represents. These appliances as indicated should not be unnecessarily expanded, but when expanded they should, wherever practicable, be converted into actively moving flying surfaces, in preference to fixed or inert dead surfaces.

The question of surface is a very important one in aviation: it naturally resolves itself into one of active and passive surface. As there are active and passive surfaces in the flying animal, so there are, or should be, active and passive surfaces in the flying machine. Art should follow nature in this matter. The active surfaces in flying creatures are always greatly in excess of the passive ones, from the fact that the former virtually increase in proportion to the spaces through which they are made to travel. Nature not only distinguishes between active and passive surfaces in the flying insect but their arrangements are such as to obviate the necessity of elevation and utilize both. She regulates the surfaces to the strength and weight of the flying creature and the air currents to which the surfaces are to be exposed and upon which they are to operate. In her calculations she never forgets that her flying subjects are to control and not to be controlled by the air. As a rule she reduces the passive surfaces of the body to a minimum; she likewise reduces as far as possible the actively moving or flying surfaces. While, however, diminishing the surfaces of the flying animal as a whole, she increases as occasion demands the active or wing surfaces by wing movements, and the passive or dead surfaces by the forward motion of the body in progressive flight. She knows that if the wings are driven with sufficient rapidity they practically convert the spaces through which they move into solid bases of support; she also knows that the body in rapid flight derives support from all the air over which it passes. The manner in which the wing surfaces are increased by the wing movements will be readily understood from the accompanying illustrations of the blow-fly with its wings at rest and in motion (figs. 8 and 9). In fig. 8 the surfaces exposed by the body of the insect and the wings are, as compared with those of fig. 9, trilling. The wing would have much more purchase on fig. 8 than on fig. 9, provided the surfaces exposed by the latter were passive or dead surfaces. But they are not dead surfaces: they represent the spaces occupied by the rapidly vibrating wings, which are actively moving flying organs. As, moreover, the wings travel at a much higher speed than any wind that blows, they are superior to and control the wind; they enable the insect to dart through the wind in whatever direction it pleases.

The reader has only to imagine figs. 8 and 9 cut out in paper to realize that extensive, inert, horizontal aeroplanes in a flying machine would be a mistake. It is found to be so practically, as will be shown by and by. Fig. 9 so cut out would be heavier than fig. 8, and if both were exposed to a current of air, fig. 9 would be more blown about than fig. 8.

It is true that in beetles and certain other insects there are the elytra or wing cases—thin, light, horned structures inclined slightly upwards—which in the act of flight are spread out and act as sustainers or gliders. The elytra, however, are comparatively long narrow structures which occupy a position in front of the wings, of which they may be regarded as forming the anterior parts. The elytra are to the delicate wings of some insects what the thick anterior margins are to stronger wings. The elytra, moreover, are not wholly passive structures. They can be moved, and the angles made by their under surfaces with the horizon adjusted. Finally, they are not essential to flight, as flight in the great majority of instances is performed without them. The elytra serve as protectors to the wings when the wings are folded upon the back of the insect, and as they are extended either on either side of the body more or less horizontally when the insect is flying they contribute to flight indirectly, in virtue of their being carried forward by the body in motion.

**Natural Flight.**—The manner in which the wings of the insect traverse the air, so as practically to increase the basis of support, raises the whole subject of natural flight. It is necessary, therefore, at this stage to direct the attention of the reader somewhat fully to the subject of flight, as witnessed in the insect, bird and bat, a knowledge of natural flight preceding, and being in some sense indispensable to, a knowledge of artificial flight. The bodies of flying creatures are, as a rule, very, very, comparatively small and of an elongated form, the bodies of birds being specially adapted for clearing the air. Flying creatures, however, are less remarkable for their strength, shape and comparative levity than for the size and extraordinarily rapid and complicated movements of their wings. Prof. J. Bell Pettigrew first satisfactorily analysed those movements, and reproduced them by the aid of artificial wings. This physiologist in 1867 showed that all natural wings, whether of the insect, bird or bat, are screws structurally, and that they act as screws when they are made to vibrate, from the fact that they twist in opposite directions during the down and up strokes. He also explained that all wings act upon a common principle, and that they present oblique, kite-like surfaces to the air, through which they pass much in the same way that an oar passes through water in sculling. He further pointed out that the wings of flying creatures (contrary to received opinions, and as has already been indicated) strike downwards and forwards during the down strokes, and upwards and forwards during the up strokes. Lastly he demonstrated that the wings of flying creatures, when the

---

1. By the term aeroplane is meant a thin, light, expanded structure inclined at a slight upward angle to the horizon intended to float or fly upon the air, and calculated to afford a certain amount of support to any body attached to it.
FLIGHT AND FLYING

505

bodies of said creatures are fixed, describe figure-of-8 tracks in space—the figure-of-8 tracks, when the bodies are released and advancing as in rapid flight, being opened out and converted into circles.

It may be well to explain here that a claim has been set up by bird-admirers for the celebrated artist, architect and engineer, Leonardo da Vinci, to be regarded as the discoverer of the principles and particulars of flight (see Andrea Cook, Spirals in Nature and Art, 1993). The claim is, however, disputed; Leonardo, it seems, simply sketched a few lines on a piece of paper, with simple sketch illustrations interspersed in the text. In addition he makes occasional references to flight in his other manuscripts, which are also illustrated. In none of Leonardo's manuscripts, however, and in none of his figures, is there any hint of the knowledge of the various intermediate degrees of obliquity, an insect with wings thus hinged may, as far as steadiness of body is concerned, be not inaptly compared to a compass set upon gimbals, where the unerring stability of the compass ensures comparative fixedness in another. . . . . All wings obtain their leverage by presenting oblique surfaces to the air, the degree of obliquity gradually increasing in a direction from behind, forwards and downwards; during extension when the sudden or effective stroke is made, and gradually decreasing in an opposite direction during flexion, or when the wing is being more slowly recovered preparatory to making a second stroke, the effective stroke in turn, and this holds true also of birds, is therefore delivered downwards and forwards, and not, as the majority of writers believe, vertically, or even slightly backwards. . . . .

Pettigrew's discovery of the figure-of-8 and waved movements made by the wing in stationary and progressive flight was confirmed some two years after it was made by Prof. E. J. Marcy of Paris1 by the aid of the ‘sphygograph’.2 The movements in question are now regarded as fundamental, from the fact that they are alike essential to natural and artificial flight.

Pettigrew's description of wings and wing movements published in 1867—

"The wings of insects and birds are, as a rule, more or less triangular in shape, the base of the triangle being directed towards the body, its sides anteriorly and posteriorly. They are also conical on section from within outwards and from before backwards, this shape converting the pinion into delicately graduated instruments balanced with the utmost nicety to satisfy the requirements of the muscular system on the one hand and with the resistance and resiliency of the air on the other. While all wings are graduated as explained, innumerable variations occur in their general contour, some being falcate or scythe-like, others oblong, others rounded or circular, some lanceolate and some linear. The wings of insects may consist either of one or two, or of a pair, when two are present and being in some instances greatly modified and presenting a curious condition. They are then known as clytra, from the Gr. Dalpo, a sheath. Both pairs are composed of a duplication of the integumentary parts, and are strengthened in various directions by a system of hollow, horny tubes, known to entomologists as the neurals or nervures. These nervures taper towards the extremity of the wing, and are strongest towards its root and anterior margin, where they supply the place of the arm in birds and bats. The neurals are arranged at the axis of the wing, after the manner of a fan or spiral-stair—the anterior one occupying a higher position than that farther back, and so of the others. As this arrangement extends also to the margins, the wings are more or less twisted upon themselves and present a certain degree of convexity on their superior or upper surface, and a corresponding concavity on their inferior or under surface, with fine edges supplying those fine curves which act with such efficacy upon the air in obtaining the maximum of resistance and the minimum of displacement. As illustrative examples of the various forms of winged animals, may be cited—

1 Revue des cours scientifiques de la France et de l‘Etranger, 1869. 2 The sphygograph, as its name indicates, is a recording instrument. It consists of a smoked cylinder revolving by means of a stylus which inscribes its surface by scratching or brushing away the lacquer. The movements to be registered are transferred to the style or pen by one or more levers, and the pen in turn transcribes the movements on to paper, where they appear upon the tracing. In registering the movements of the wings the tips and margins of the pinions were, by an ingenious modification, employed as the styles or pens. By this arrangement the parts — the tip, middle, and base — were made to act as actual parts of their own movements. As will be seen from this account, the figure-of-8 or wave theory of stationary and progressive flight has been made the subject of a rigorous experiment in crucis.

3 This continuity of the down into the up stroke and the converse is greatly facilitated by the elastic ligaments at the root and in the
FLIGHT AND FLYING

"The wing of the bird, like that of the insect, is concavo-convex, and more or less twisted upon itself when extended, so that the anterior or thick margin of the pinion presents a different degree of curvature to that of the posterior or thin margin. This twisting is in a great measure owing to the manner in which the bones of the wing are twisted upon themselves, and the spiral nature of their articular surfaces—the long axes of the joints always intersecting each other at right angles, and the bones of the elbow and wrist making a quarter of a turn or so during extension and the same amount during flexion. As a result of this disposition of the articular surfaces, the wing may be shot out or extended, and retracted or flexed in nearly the same plane, the bones composing the wing rotating on their axes during either movement (fig. 14). The secondary action, or the revolving of the component bones on their own axes, is of the greatest importance in the movements of the wing, as it communicates to the hand and forearm, and consequently to the primary and secondary feathers which they bear, the precise angles necessary for flight. It in fact ensures that the elbow and the curtain flanges of the wing which the primary and secondary feathers form, shall be screwed into and down upon the wind in extension, and unscrewed or withdrawn from the wind during flexion. The wing of the bird may therefore be compared to a huge propeller, the axis of the gimlet representing the bones of the wing, the flanges or spiral thread of the gimlet the primary and secondary feathers " (figs. 15 and 16).

"From this description it will be evident that by the mere rotation of the bones of the forearm and hand the maximum and minimum of resistance is secured much in the same way that this object is attained by the alternate dipping and feathering of the wing. Thus the general outline of the wing corresponds closely with the outline of the propeller (figs. 11, 16 and 18), and the track described by the wing in space is drawn upon itself in a figure of 8 or some other form. The great velocity with which the wing is driven converts the impression or blur made by it into what is equivalent to a blade of an ordinary screw. The substance for the time being, in the same way that the spokes of a wheel in violent motion, as is well understood, more or less completely occupy the space contained within the rim or circumference of the wheel " (figs. 9, 20 and 21).

"The wing of the bat bears a considerable resemblance to that of the insect, inasmuch as it consists of a delicate, semi-transparent, and continuous membrane, supported in divers directions, particularly towards its anterior margin, by a system of osseous stays or stretchers which confer upon it the degree of rigidity requisite for flight. It is, as a rule, deeply concave on its under or ventral surface, and in this respect resembles the wing of the heavy-bodied birds. The method of the movement of the bat's wing in extension is a spiral one, the spiral running alternately from below upwards and forwards and from above downwards and backwards. The action of the wing of the bat, and the movements of its component bones, are essentially the same as in the bird " (figs. 17 and 18).

"...The wing strikes the air precisely as a boy's kite would if it were jerked by its string, the only difference being that the kite is pushed forwards upon the wind by the string and the hand, whereas in the insect, bird and bat the wing is pushed forwards on the wind by the weight of the body and the power residing in the pinion itself " (fig. 19).

"The figure-of-8 and kite-like action of the wing referred to lead us to explain how it happens that the wing, which in many instances is a comparatively small and delicate organ, can yet attack the air with such vigour as to extract from it the recoil necessary to elevate and propel the flying creature. The accompanying figures, from one of Petitgrad, later memoirs will serve to explain the rationale (figs. 20, 21, 22 and 23).

As will be seen from these figures, the wing during its vibration sweeps through a comparatively large space. This space, as already explained, is practically a solid basis of support for the wing and for the flying animal. The wing attacks the air in such a manner as virtually to have no slip—this for two reasons. The wing reverses instantly and acts as a kite during nearly the entire down and up strokes. The angles, moreover, made by the wing with the horizon during the down and up strokes are at no two intervals the same, but (and this is a wing of the martin, where the bones of the pinion are short, and in some respects rudimentary, the primary and secondary feathers are greatly developed, and banked up in such a manner that the wing as a whole presents the same curves as those displayed by the insect's wing, or by the wing of the eagle, where the bones, muscles and feathers have attained a maximum development. The configuration of the wing is such that it presents a waved appearance in every direction—the waves running longitudinally, transversely and obliquely. The greater portion of the wing may consequently be removed without essentially altering either its form or its functions. This is proved by making sections in various directions, and by finding that in some instances as much as two-thirds of the wing may be lopped off without materially impairing the power of flight."—Trans. Roy. Soc. Edin. vol. xxxvi. pp. 325, 336.

2 "On the Physiology of Wings: being an analysis of the movements by which flight is produced in the Insect, Bat and Bird," Trans. Roy. Soc. Edin. vol. xvi.

remarkable circumstance) they are always adapted to the speed at which the wing is travelling for the time being. The increase and decrease in the angles made by the wing as it hastens to and fro are due partly to the resistance offered by the air, and partly to the mechanism and mode of application of the wing to the air. The wing, during its vibrations, rotates upon two separate centres, the tip rotating round the root of the wing as an axis (short axis of wing), the posterior margin rotating around the anterior margin (long axis of wing). The wing is really eccentric in its nature, a remark which applies also to the rowing feathers of the bird's wing. The compound rotation goes on throughout the entire down and up strokes, and is intimately associated with the power which the wing enjoys of alternately seizing and evading the air.

The compound rotation of the wing is greatly facilitated by the wing being elastic and flexible. It is this which causes the wing to twist and untwist diagonally on its long axis when it is made to vibrate. The twisting referred to is partly a vital and partly a mechanical act;—that is, it is occasioned in part by the action of the muscles and in part by the greater resistance experienced from the air by the tip and posterior margin of the wing as compared with the root and anterior margin,—the resistance experienced by the tip and posterior margin causing them to reverse always subsequently to the root and anterior margin, which has the effect of throwing the anterior and posterior margins of the wing into figure-of-8 curves, as shown at figs. 9, 11, 12, 16, 18, 20, 21, 22 and 23.

The compound rotation of the wing, as seen in the bird, is represented in fig. 24.

Not the least curious feature of the wing movements is the remarkable power which the wings possess of making and utilizing its own currents. Thus, when the wing descends it draws after it a strong current, which, being met by the wing during its ascent, greatly increases the efficacy of the up stroke. Similarly and conversely, when the wing ascends, it creates an upward current, which, being met by the wing when it descends, powerfully contributes to the efficiency of the down stroke. This statement can be readily verified by experiment both with natural and artificial wings. Neither the up nor the down strokes are complete in themselves.

The wing to act efficiently must be driven at a certain speed, and in such a manner that the down and up strokes shall glide into each other. It is only in this way that the air can be made to pulsate, and that the rhythm of the wing and the air waves can be made to correspond. The air must be seized and let go in a certain order and at a certain speed to extract a maximum recoil. The rapidity of the wing movements is regulated by the size of the wing, small wings being driven at a very much higher speed than larger ones. The different parts of the wing, moreover, travel at different degrees of velocity—the tip and posterior margin of the wing always rushing through a much greater space, in a given time, than the root and anterior margin.

Fig. 20.

Figs. 20, 21, 22 and 23 show the area mapped out by the left wing of the Wasp when the insect is fixed and the wing made to vibrate. These figures illustrate the various angles made by the wing with the horizon as it hastens to and fro, and show how the wing reverses and reciprocates, and how it twists upon itself in opposite directions, and describes a figure-of-8 track in space. Figs. 20 and 22 represent the forward or down stroke (a b d e f g), figs. 21 and 23 the backward or up stroke (h j k l). The terms forward and back strokes are here employed with reference to the head of the insect. x, x', line to represent the horizon. If fig. 22, representing the down or forward stroke, be placed upon fig. 23, representing the up or backward stroke, it will be seen that the wing crosses its own track more or less completely at every stage of the down and up strokes.

The rapidity of travel of the insect wing is in some cases enormous. The wasp, for instance, is said to ply its wings at the rate of 110, and the common house-fly at the rate of 330 beats per second. Quick as are the vibrations of natural wings, the speed of certain parts of the wing is amazingly increased. Wings as a rule are long and narrow. As a consequence, a comparatively slow and very limited movement at the root confers great range and immense speed at the tip, the speed of each portion of the wing increasing as the root of the wing is receded from this is explained on a principle well understood in mechanics, viz., that when a wing or rod hinged at one end is made to move in a circle, the tip or free end of the wing or rod describes a much wider circle in a given time than a portion of the wing or rod nearer the hinge (fig. 25).

One naturally inquires why the high speed of wings, and why the progressive increase of speed at their tips and posterior margins? The answer is not far to seek. If the wings were not driven at a high speed, and if they were not eccentrics made to revolve upon two separate axes, they would of necessity be large cumbersome structures; but large heavy wings would be difficult to work, and what is worse, they would (if too large), instead of controlling the air, be controlled by it, and so cease to be flying organs.

There is, however, another reason why wings should be made to vibrate at high speeds. The air, as explained, is a very light, thin, elastic medium, which yields on the slightest pressure, and unless the wings attacked it with great violence the necessary recoil or resistance could not be obtained. The atmosphere, because of its great tenuity, mobility and comparative imponderability, presents little resistance to bodies passing through it at low velocities. If, however, the speed be greatly accelerated,
the action of even an ordinary cane is sufficient to elicit a recoil. This comes of the action and reaction of matter, the resistance experienced varying according to the density of the atmosphere and the shape, extent and velocity of the body acting upon it. While, therefore, scarcely any impediment is offered to the progress of an animal in motion in the air, it is often exceedingly difficult to compress the air with sufficient rapidity and energy to convert it into a suitable fulcrum for securing the necessary support and forward impetus. This arises from the fact that bodies moving in air experience a minimum of resistance and occasion a maximum of displacement. Another and very obvious difficulty is traceable to the great disparity in the weight of air as compared with any known solid, and the consequent want of buoying or sustaining power which that disparity involves. If we compare air with water we find it is nearly 1000 times lighter. To meet these peculiarities the insect, bird and bat are furnished with extensive flying surfaces in the shape of wings, which they apply with singular velocity and power to the air, as levers of the third order. In this form of lever the power is applied between the fulcrum and the weight to be raised. The power is represented by the air, the fulcrum by the body, and the weight by the body of the flying animal. Although the third order of lever is particularly inefficient when the fulcrum is rigid and immobile, it possesses singular advantages when these conditions are reversed, that is, when the fulcrum, as happens with the air, is elastic and yielding. In this instance a very slight movement at the root of the pinion, or that end of the lever directed towards the body, is followed by an immense sweep of the extremity of the wing, where its elevating and propelling power is greatest—this arrangement ensuring that the large quantity of air necessary for support and propulsion shall be compressed under the most favourable conditions.

In this process the weight of the body performs an important part, by acting upon the inclined planes formed by the wings in the plane of progression. The power and the weight may thus be said to reciprocate, the two sitting as it were side by side and blending their peculiar influences to produce a common result, as indicated at fig. 26.

When the wings descend they elevate the body, the wings being active and the body passive; when the body descends it contributes to the elevation of the wings, the body being exerted in a direction opposite to that of the weight.

The weight of the body plays an important part in the production of flight may be proved by a very simple experiment. If two quill feathers are fixed in an ordinary cork, and so arranged that they expand and arch above it (fig. 27), it is found that if the apparatus be dropped from a vertical height of 3 yds. it does not fall vertically downwards, but downwards and forwards in a quadrant, the forward travel amounting in some instances to a yard and a half. Here the cork, in falling, acts upon the feathers (which are to all intents and purposes wings), and these in turn act upon the air, in such a manner as to produce a horizontal transference.

In order to utilize the air as a means of transit, the body in motion, whether it moves in virtue of the life it possesses, or because of a force superadded, must be heavier than air. It must tread with its wings and rise upon the air as a swimmer upon the water, or as a kite upon the wind. This is necessary for the simple reason that the body must be active, the air passive. The flying body must act against gravitation, and elevate and carry itself forward at the expense of the air and of the force which resides in it, whatever that may be. If it were otherwise—if it were rescued from the law of gravitation on one hand, and bereft of independent movement on the other, it would float about uncontrolled and uncontrollable like an ordinary balloon.

In flight one of two things is necessary. Either the wings must attack the air with great violence, or the air in rapid motion must attack the wings: either suffices. If a bird attempts to fly in a calm, the wings must be made to smite the air after the manner of a boy's kite with great vigour and at a high speed. In this case the wings fly the bird. If, however, the bird is fairly launched in space and a still breeze is blowing, all that is required in many instances is to extend the wings at a slight upward angle to the horizon so that the under parts of the wings present kite-like surfaces. In these circumstances the rapidly moving air flies the bird. The flight of the albatross supplies the necessary illustration. If by any chance this magnificent bird alights upon the sea he must flap and beat the water and air with his wings with tremendous energy until he gets fairly launched. This done he extends his enormous pinions and sails majestically along, seldom deigning to flap his wings, the breeze doing the work for him. A familiar illustration of the same principle may be witnessed any day when children are engaged in the pastime of kite-flying. If two boys attempt to fly a kite in a calm, the one must hold up the kite and let go when the other runs. In this case the under surface of the kite is made to strike the still air. If, however, a stiff autumn breeze is blowing, it suffices if the boy who formerly ran when the kite was let go stands still. In this case the air in rapid motion strikes the under surface of the kite and forces it up. The string and the hand are to the kite what the weight of the flying creature is to the inclined planes formed by its wings.

The area of the insect, bird and bat, when the wings are fully expanded, is greater than that of any other class of animal, their weight being proportionally less. As already stated, however, it ought never to be forgotten that even the lightest insect, bird or bat is vastly heavier than the air, and that no fixed relation exists between the weight of body and expanse of wing in any of the orders. We have thus light-bodied and

---

1 The other forces which assist in elevating the wings are—(a) the elevator muscles of the wings, (b) the elastic properties of the wings, and (c) the reaction of the compressed air on the under surfaces of the wings.

2 The wings of the albatross, when fully extended, measure across the back some 14 ft. They are exceedingly narrow, being sometimes under a foot in width.
large-winged insects and birds, as the butterfly and heron; and others with heavy bodies and small wings, as the beetle and partridge. Similar remarks are to be made of bats. These apparent inconsistencies in the dimensions of the body and wings are readily explained by the greater muscular development of the heavy-bodied, small-winged insects, birds and bats, and the increased power and rapidity with which the wings in them are made to oscillate. This is of the utmost importance in the science of aviation, as showing that flight may be attained by a heavy powerful animal with comparatively small wings, as well as by a lighter one with greatly enlarged wings. While, therefore, there is apparently no correspondence between the area of the wing and the animal to be raised, there is, except in the case of sailing insects, birds and bats, an unvarying relation as to the weight and number of oscillations; so that the problem of flight would seem to resolve itself into one of weight, power, velocity and small surfaces, versus buoyancy, debility, diminished speed and extensive surfaces—weight in either case being a sine qua non.

That no fixed relation exists between the area of the wings and the size and weight of the body to be elevated is evident on comparing the dimensions of the wings and bodies of the several orders of insects, bats and birds. If such comparison be made, it will be found that the pinions in some instances diminish while the bodies increase, and the converse. No practical good can therefore accrue to aviation from elaborate measure of the wings and body of any flying thing; neither can any rule be laid down as to the extent of surface required for sustaining a given weight in the air. The statements here advanced are borne out by the fact that the wings of insects, bats and birds may be materially reduced without impairing their powers of flight. In such cases the speed with which the wings are driven is increased in the direct ratio of the mutilation.

The inference to be deduced from the foregoing is plainly this, that even in large-bodied, small-winged insects and birds the wing-surface is greatly in excess, the surplus wing area supplying this we have a partial explanation of the buoyancy of insects, and the great lifting power possessed by birds and bats,—the bats carrying their young without inconvenience, the birdselevating surprising quantities of fish, game, carrion, &c. (fig. 28).

While as explained, no definite relation exists between the weight of a flying animal and the size of its flying surfaces, there being, as stated, heavy-bodied and small-winged insects, birds and bats, and the converse, and while, as has been shown, flight is possible within a wide range, the wings being, as a rule, in excess of what are required for the purposes of flight,—still it appears from the researches of L. de Lucy that there is a general law, to the effect that the larger the volant animal, the smaller, by comparison, are its flying surfaces. The existence of such a law is very encouraging so far as artificial flight is concerned, for it shows that the flying surfaces of a large, heavy, powerful flying machine will be comparatively small, and consequently comparatively compact and strong. This is a point of very considerable importance, as the object desired in a flying machine is elevating capacity.

De Lucy tabulated his results as under:

"It is easy, by the aid of this table, to follow the order, always decreasing, of the surfaces, in proportion as the winged animal increases in size and weight. Thus, in comparing the insects with one another, we find that the gnat, which weighs 450 times less than the stag-beetle, has 14 times more surface. The lady-bird weighs 150 times less than the stag-beetle, and possesses 5 times more surface, &c. It is the same with the birds. The sparrow weighs about 10 times less than the pigeon, and has twice as much surface. The drake weighs about 8 times less than the stork, and has twice as much surface. The sparrow weighs 330 times less than the Australian crane, and possesses 7 times more surface, &c. If now we compare the insects and the birds, the gradation will become even much more striking. The gnat, for example, weighs 97,000 times less than the pigeon, and has 40 times more surface; it weighs three millions of times less than the crane of Australia, and possesses 140 times more of surface than this latter, the weight of which is about 9 kilogrammes 500 grammes (25 lb 5 oz. 9 dwt. troy, 20 lb 15 oz. 21 dr. avoirdupois).

The Australian crane, the heaviest bird weighed, is that which has the smallest amount of surface, for, referred to the kilogramme, it does not give us a surface of more than 899 square centimetres (139 sq. in.), that is to say, about an eleventh part of a square metre. But every one knows that these grallatorial animals are excellent birds of flight. Of all travelling birds they undertake the longest and most remote journeys. They are, in addition, the eagle excepted, the birds which elevate themselves the highest, and the flight of which is the longest maintained."

The way in which the natural wing rises and falls on the air, and reciprocates with the body of the flying creature, has a very obvious bearing upon artificial flight. In natural flight the body of the flying creature falls slightly forward in a curve when the

> Fig. 28.—Hawk and Pigeon.

that degree of elevating and sustaining power which is necessary to prevent undue exertion on the part of the volant animal. In

1 On the Flight of Birds, of Bats and of Insects, in reference to the subject of Aerial Locomotion, by L. de Lucy (Paris).
wing ascends, and is slightly elevated in a curve when the wing descends. The wing and body are consequently always playing at cross purposes, the wing rising when the body is falling and vice versa. The alternate rise and fall of the body and wing of the bird are well seen when contemplating the flight of the gull from the stern of a steamboat, as the bird is following in the wake of the vessel. The complementary movements referred to are indicated at fig. 29, where the continuous waved line represents the trajectory made by the wing, and the dotted waved line made by the body. As will be seen from this figure, the wing advances both when it rises and when it falls. It is a peculiarity of natural wings, and of artificial wings constructed on the principle of living wings, that when forcibly elevated or depressed, even in a strictly vertical direction, they inevitably dart forward. If, for instance, the wing is suddenly depressed in a vertical direction, as at e d of fig. 29, it at once darts downwards and forwards in a double curve (see continuous line of figure) c, thus converting the vertical down stroke into a down, oblique, forward stroke. If, again, the wing be suddenly elevated in a strictly vertical direction, as at e, the wing as certainly darts upwards and forwards in a double curve to e, thus converting the vertical up stroke into an up,ward, oblique, forward stroke. The same thing happens when the wing is depressed from e to f and elevated from g to h, the wing describing a waved track as at g, g f.

There are good reasons why the wings should always be in advance of the body. A bird when flying is a body in motion; but a body in motion tends to fall not vertically downwards, but downwards and forwards. The wings consequently must be made to strike forwards and kept in advance of the body of the bird if they are to prevent the bird from falling downwards and forwards. If the wings were to strike backwards in aerial flight, the bird would turn a forward somersault.

That the wings invariably strike forwards during the down and up strokes in aerial flight is proved alike by observation and experiment. If any one watches a bird rising from the ground or the water, he cannot fail to perceive that the head and body are slightly tilted upwards, and that the wings are made to descend with great vigour in a downward and forward direction. The dead natural wing and a properly constructed artificial wing act in precisely the same way. If the wing of a gannet, just shot, be removed and made to flap in what the operator believes to be a strictly vertical downward direction, the tip of the wing, in spite of him, will dart forwards between 2 and 3 ft. —the amount of forward movement being regulated by the rapidity of the down stroke. This is a very striking experiment. The same thing happens with a properly constructed artificial wing. The down stroke with the artificial as with the natural wing is invariably converted into an oblique, downward and forward stroke. No one ever saw a bird in the air flapping its wings towards its tail. The old idea was that the wings during the down stroke pushed the body of the bird in an upward and forward direction; in reality the wings do not push but pull, and in order to pull they must always be in advance of the body to be flown. If the wings did not themselves fly forward, they could not possibly cause the body of the bird to fly forward. It is the wings which cause the bird to fly.

It only remains to be stated that the wing acts as a true kite, during both the down and the up strokes, its under concave or bitting surface, in virtue of the forward travel communicated to it by the body of the flying creature, being closely applied to the air, during both its ascent and its descent. This explains how the wing furnishes a persistent buoyancy alike when it rises and when it falls (fig. 30).

The natural kite formed by the wing differs from the artificial kite only in this, that the former is capable of being moved in all its parts, and is more or less flexible and elastic, whereas the latter is comparatively rigid. The flexibility and elasticity of the wings, assumed by the natural wing are rendered necessary by the fact that the wing, as already stated, is practically hinged at its root and along its anterior margin, an arrangement which necessitates its several parts travelling at different degrees of speed, in proportion as they are removed from the axes of rotation. Thus the tip travels at a higher speed than the root, and the posterior margin than the anterior margin. This begets a twisting diagonal movement of the wing on its long axis, which, but for the elasticity referred to, would break the wing into fragments. The elasticity contributes also to the continuous play of the wing, and ensures that no two parts of it shall reverse at exactly the same instant. If the wing was inelastic, every part of it would reverse at precisely the same moment, and its vibration would be characterized by pauses or dead points at the end of the down and up strokes which would be fatal to it as a flying organ.

Fig. 29 shows how in progressive flight the wing and the body describe waved tracks—the crests of the waves made by the wing (a, c, e, g, i) being placed opposite the crests of the waves made by the body (1, 2, 3, 4, 5).

Fig. 30 shows the kite-like action of the wing during the down and up strokes, how the angles made by the wings with the horizon (a, b) vary at every stage of these strokes, and how the wing was an instrument for converting the superimposed air during the up stroke, and seizes the nether air during the down stroke. In this figure the spaces between the double dotted lines e g, f h, j k, m, n, o, p, q, and the single dotted line (h, i) representing the up stroke. The kite-like surfaces and angles made by the wing with the horizon (a, b) during the down strokes are indicated at e d f g, j k l m, n, o, p, q, those made during the up strokes being indicated at e f g i. As the down and up strokes run into each other, and the convex surface of the wing is always directed upwards and the concave surface downwards, it follows that the upper surface of the wave evades in a great measure the upper air, while the under surface seizes the nether air. It is easy to understand from this figure how the wing always flying forwards furnishes a persistent buoyancy.

The elastic properties of the wing are absolutely essential, when the mechanism and movements of the pinion are taken into account. A rigid wing can never be an effective flying instrument.

The kite-like surfaces referred to in natural flight are those upon which the constructors of flying machines very properly ground their hopes of ultimate success. These surfaces may be referred on artificial wings, aeroplanes, aerial screws or similar structures; and these structures, if we may judge from what we find in nature, should be of moderate size and elastic. The power of the flying organs will be increased if they are driven at a comparatively high speed, and particularly if they are made to reverse and reciprocate, as in this case they will practically create the currents upon which they are destined to rise and advance. The angles made by the kite-like surfaces with the horizon should vary according to circumstances. They should be small when the speed is high, and vice versa. This, as stated, is true of natural wings. It should also be true of artificial wings and their analogues.

Artificial Flight.—We are now in a position to enter upon a consideration of artificial wings and wing movements, and of artificial flight and flying machines.

We begin with artificial wings. The first properly authenticated account of an artificial wing was given by G. A. Borelli in 1650. This author, distinguished alike as a physiologist, mathematician and mechanician, described and figured and with artificial wings, each of which consists of a rigid rod in front and flexible feathers behind. The wings are represented as striking vertically downwards, as the annexed duplicate of Borelli's figure shows (fig. 31).

Borelli was of opinion that flight resulted from the application of an inclined plane, which beats the air, and which has a wedge
action. He, in fact, endeavours to prove that a bird wedges itself forward upon the air by the perpendicular vibration of its wings, the wings during their action forming a wedge, the base of which (c b e) is directed towards the head of the bird, the apex (a f) being directed towards the tail (d). In the 10th proposition of his work (De motu animalium, Leiden, 1655) he states that—

"If the expanded wings of a bird suspended in the air shall strike the undisturbed air beneath it with a motion perpendicular to the horizon, the bird will fly with a transverse motion, and will be horizontal to the horizon."

"If it," he adds, "the wings of the bird be expanded, and the under surfaces of the wings be struck by the air ascending perpendicularly to the horizon with such a force as shall prevent the bird gliding downwards (i.e. with an impetus to glide downwards) from falling, it will be urged in a horizontal direction."

The same argument is restated in different words as under—

"If the air under the bird be struck by the flexible portions of the wings (flabella, literally flexible flaps or small fans) with a motion perpendicular to the horizon, the sails (c d e f g) and flexible portions of the wings (flabella) will yield in an upward direction and form a wedge, the point of which is directed towards the tail. Whereas, therefore, the air strikes the wings from below, or the wings strike the air from above, the result is the same,—the posterior or flexible margins of the wings yield in an upward direction, and in so doing urge the bird in a horizontal direction."

There are three points in Borelli's argument to which it is necessary to draw attention: (1) the direction of the down stroke: it is stated to be vertically downwards; (2) the construction of the anterior margin of the wing: it is stated to consist of a rigid rod; (3) the function delegated to the posterior margin of the wing: it is said to yield in an upward direction during the down stroke.

With regard to the first point. It is incorrect to say the wing strikes vertically downwards, for, as already explained, the body of a flying bird is a body in motion; but as a body in motion tends to fall downwards and forwards, the wing must strike downwards and forwards in order effectually to prevent its fall. Moreover, in point of fact, all natural wings, and all artificial wings constructed on the natural type, invariably strike downwards and forwards.

With regard to the second point, viz., the supposed rigidity of the anterior margin of the wing, it is only necessary to examine the anterior margins of natural wings to be convinced that they are in every case flexible and elastic. Similar remarks apply to properly constructed artificial wings. If the anterior margins of natural and artificial wings were rigid, it would be impossible to make them vibrate smoothly and continuously. This is a matter of experiment. If a rigid vertical wing is made to vibrate, the vibration is characterized by an unequal jerky motion, at the end of the down and up strokes, which contrasts strangely with the smooth, steady fanning movement peculiar to natural wings.

As to the third point, viz. the upward bending of the posterior margin of the wing during the down stroke, it is necessary to remark that the statement is true if it means a slight upward bending, but that it is untrue if it means an extensive upward bending.

Borelli does not state the amount of upward bending, but one of his followers, E. J. Marey, maintains that during the down stroke the wing yields until its under surface makes a backward angle with the horizon of 45°. Marey further states that during the up stroke the wing yields to a corresponding extent in an opposite direction—the posterior margin of the wing, according to him, passing through an angle of 90°, plus or minus according to circumstances, every time the wing rises and falls.

That the posterior margin of the wing yields to a slight extent during both the down and up strokes will readily be admitted, alike because of the very delicate and highly elastic properties of the posterior margins of the wing, and because of the comparatively great force employed in its propulsion; but that it does not yield to the extent stated by Marey is a matter of absolute certainty. This admits of direct proof. If any one observes the horizontal or upward flight of a large bird he will observe that the posterior or flexible margin of the wing never rises during the down stroke to a perceptible extent, so that the under surface of the wing, as a whole, never looks backwards. On the contrary, he will perceive that the under surface of the wing (during the down stroke) invariably looks forwards and forms a true kite with the horizon, the angles made by the kite varying at every part of the down stroke, as shown more particularly at ed e f g, i k l m of fig. 30.

The authors who have adopted Borelli's plan of artificial wing, and who have endorsed his mechanical views of the wing's action most fully, are J. Chabrier, H. E. G. Strauss-Dürckheim and Marey. Borelli's artificial wing, it will be remembered, consists of a rigid rod in front and a flexible sail behind. It is also made to strike vertically downwards. According to Chabrier, the wing has only one period of activity. He believes that if the wing be suddenly lowered by the depressor muscles, it is elevated solely by the reaction of the air. There is one unanswerable objection to this theory: the birds and bats, and some if not all the insects, have no fixed elevators, and can elevate their wings at pleasure when not flying and when, consequently, the reaction of the air is not elicited. Strauss-Dürckheim agrees with Borelli both as to the natural and the artificial wing. He is of opinion that the insect abstractions from the air by means of the inclined plane a component force (composant) which it employs to support and direct itself. In his theology of nature he describes a schematic wing as consisting of a rigid ribbing in front, and a flexible sail behind. A membrane so constructed will, according to him, be fit for flight. It will suffice if such a sail elevates and lowers itself successively. It will of its own accord dispose itself as an inclined plane, and receiving obliquely the reaction of the air, it transfers into tractile force a part of the vertical impulsion it has received. These two parts of the wing, moreover, are equally indispensable to each other.

Marey repeats Borelli and Dürckheim with very trifling modifications, so late as 1869. He describes two artificial wings, the one composed of a rigid rod and sail—the rod representing the anterior margin of the wing; the sail, which is made of paper bordered with cardboard, the flexible posterior margin.

The other wing consists of a rigid nervure in front and behind of thin parchment which supports fine rods of steel. He states that if the wing only elevates and depresses itself, "the resistance of the air is sufficient to produce all the other movements. In effect (according to Marey) the wing of an insect has not the power of equal resistance in every part. On the anterior margin the extended nervures make it rigid, while behind it is fine and flexible. During the vigorous depression of the wing, the nervure has the power of remaining rigid, whereas the flexible portion, being pushed in an upward direction on account of the resistance it experiences from the air, assumes an oblique position which causes the upper surface of the wing to look forwards." The reverse of this, in Marey's opinion, takes place during the elevation of the wing—the resistance of the air from above causing the upper surface of the wing to look backwards. "At first," he says, "the plane of the wing is parallel with the body of the animal. It lowers itself—the front part of the wing strongly resists the air which does not support it. The posterior part, or the ribbing (the anterior margin of the wing) which lowers itself, the sail or posterior margin of the wing being raised meanwhile by the air, which sets it straight again, the sail will take an intermediate position and incline itself about 45° plus or minus according to circumstances. . . . The wing continues its movements of depression inclined to the horizon; but the impulse of the air,
which continues its effect, and naturally acts upon the surface which it strikes, has the power of resolving itself into two forces, a vertical and a horizontal force; the first suffices to raise the animal, the second to move it along."¹ Marcy, it will be observed, reproduces Borell's artificial wing, and even his text, at a distance of nearly two centuries.

The artificial wing recommended by Pettigrew is a more exact imitation of nature than either of the foregoing. It is of a more or less triangular form, thick at the root and anterior margin, and thin at the tip and posterior margin. No part of it is rigid. It is, on the contrary, highly elastic and flexible throughout. It is furnished with springs at its root to contribute to its continued play, and is applied to the air by a direct piston action in such a way that it descends in a downward and forward direction during the down stroke, and ascends in an upward and forward direction during the up stroke. It elevates and propels both when it rises and falls. It, moreover, twists and untwists during its action and describes figure-of-8 and waved tracks in space, precisely as the natural wing does. The twisting is most marked at the tip and posterior margin, and is particularly that half of the posterior margin next the tip. The wing when in action may be divided into two portions by a line running diagonally between the tip of the wing anteriorly and the root of the wing posteriorly. The tip and posterior parts of the wing are more active than the root and anterior parts, from the fact that the tip and posterior parts (the wing is an eccentric) always travel through greater spaces, in a given time, than the root and anterior parts.

The wing is so constructed that the posterior margin yields freely in a downward direction during the up stroke, while it yields comparatively little in an upward direction during the down stroke; and this is a distinguishing feature, as the wing is thus made to fold and elude the air more or less completely during the up stroke, whereas it is made to expand and seize the air with avidity during the down stroke. The oblique line referred to as running diagonally across the wing virtually divides the wing into an active and a passive part, the former elevating and propelling, the latter sustaining.

It is not possible to determine with exactitude the precise function discharged by each part of the wing, but experiment tends to show that the tip of the wing elevates, the posterior margin propels, and the root sustains.

The wing—and this is important—is driven by a direct piston action with an irregular hammer-like movement, the pinion having communicated to it a smart click at the beginning of every down stroke—the up stroke being more uniform. The following is the arrangement (fig. 32). If the artificial wing here represented (fig. 32) be compared with the natural wing as depicted at fig. 33, it will be seen that there is nothing in the one which is not virtually reproduced in the other. In addition to the foregoing, Pettigrew recommended a double elastic wing to be applied to the air like a steam-hammer, by being fastened to the head of the piston. This wing, like the single wing described, twists and untwists as it rises and falls, and possesses all the characteristics of the natural wing (fig. 34).

He also recommends an elastic aerial screw consisting of two blades, which taper and become thinner towards the tips and posterior margins. When the screw is made to rotate, the blades, because of their elasticity, assume a great variety of angles, the angles being least where the speed of the blades is greatest and vice versa. The pitch of the blades is thus regulated by the speed attained (fig. 35).

The peculiarity of Pettigrew's wings and screws consists in their elasticity, their twisting action, and their great comparative length and narrowness. They offer little resistance to the air when they are at rest, and when in motion the speed with which they are driven is such as to ensure that the comparatively large spaces through which they travel shall practically be converted into solid bases of support.

After Pettigrew enunciated his views (1867) as to the screw configuration and elastic properties of natural wings, and more especially after his introduction of spiral, elastic artificial wings, and elastic screws, a great revolution took place in the construction of flying models. Elastic aeroplanes were advocated by

---

D. S. Brown, elastic aerial screws by J. Armour, and elastic aeroplanes, wings and screws by Alphonse Pénaud.

Pénaud’s experiments are alike interesting and instructive. He constructed models to fly by three different methods:—

(a) by means of screws acting vertically upwards; (b) by aeroplanes propelled horizontally by screws; and (c) by wings which

ab, ef, tapering elastic rods forming flapped in an upward and downward direction. An account of his hélicoptère or screw model appeared in the Aeronaut for January 1872, but before giving a description of it, it may be well to state very briefly what is known regarding the history of the screw as applied to the air.

The first suggestion on this subject was given by A. J. P. Paucton in 1768. This author, in his treatise on the Théorie de la vis d’Archimède, describes a machine provided with two screws which he calls a “ptérophores.” In 1796 Sir George Cayley gave a practical illustration of the efficacy of the screw as applied to the air by constructing a small machine, consisting of two screws made of quill feathers, a representation of which we annex (fig. 36). Sir George writes as under:

"As it may be an amusement to some of your readers to see a machine rise in the air by mechanical means, I will conclude my present communication by describing an instrument of this kind, which any one can construct at the expense of ten minutes’ labour.

The Aeronaut for January 1872 and February 1875.

"a and b, fig. 36, are two corks, into each of which are inserted four wing feathers from any bird, so as to be slightly inclined like the sails of a mill, but in opposite directions in each set. A round shaft is fixed in the cork b, which ends in a sharp point. At the upper part of the cork a is fixed a whalebone bow, having a small pivot hole in its centre to receive the point of the shaft. The bow is then to be strung equally on each side to the upper portion of the shaft, and the little machine is completed. Wind up the string by turning the flyers different ways, so that the spring of the bow may unwind them with their anterior edges ascending; then place the cork with the bow attached to it upon a table, and with a finger on the upper cork press strong enough to prevent the string from unwinding, and, taking it away suddenly, the instrument will rise to the ceiling."

Cayley’s screws were peculiar, inasmuch as they were superimposed and rotated in opposite directions. He estimated that if the area of the screws was increased to 200 sq. ft., and moved by a man, they would elevate him. His interesting experiment is described at length, and the apparatus figured in Nicolson’s Journal, 1860, p. 172.

Other experimenters, such as J. Degen in 1816 and Ottorii Sarti in 1823, followed Cayley at moderate intervals, constructing flying models on the vertical screw principle. In 1842 W. H. Phillips succeeded, it is stated, in elevating a steam model by the aid of revolving fans, which according to his account flew across two fields after having attained a great altitude; and in 1859 H. Bright took out a patent for a machine to be sustained by vertical screws. In 1863 the subject of aviation by vertical screws received a fresh impulse from the experiments of Gustave de Ponton d’Amécourt, G. de la Landelle, and A. Nadar, who exhibited models driven by clock-work springs, which ascended with graduated weights a distance of from 10 to 12 ft. These models were so fragile that they usually broke in coming in contact with the ground in their descent. Their flight, moreover, was unsatisfactory, from the fact that it only lasted a few seconds.

FIG. 36.—Cayley’s Flying Model.

FIG. 37.—De la Landelle’s Flying-machine. m, n, o, p; g, r, s, t, Screws arranged on vertical axes to act vertically upwards. The vertical axes are surmounted by two parachutes, and the body of the machine is furnished with an engine, propeller, rudders and an extensive aero-plane.

Stimulated by the success of his spring models, Ponton d’Amécourt had a small steam model constructed. This model, which was shown at the exhibition of the Aeronautical Society of Great Britain at the Crystal Palace in 1868, consisted of two superposed screws propelled by an engine, the steam for which was generated (for lightness) in an aluminium boiler. This steam model proved a failure, inasmuch as it only lifted a third of its own weight. Fig. 37 embodies de la Landelle’s ideas.
All the models referred to (Cayley’s excepted) were provided with rigid screws. In 1872 Penaud discarded the rigid screws in favour of elastic ones, as Pettigrew had done some years before. Penaud also substituted india-rubber under torsion for the whalebone and clock springs of the smaller models, and the steam of the larger ones. His hélicoptère or screw-model is remarkable for its lightness, simplicity and power. The accompanying sketch will serve to illustrate its construction (fig. 38). It consists of two superposed elastic screws (a a, b b), the upper of which (a a) is fixed in a vertical frame (e), which is pivoted in the central part (d) of the under screw. From the centre of the under screw an axle provided with a hook (e), which performs the part of a crank, projects in an upward direction. Between the hook or crank (e) and the centre of the upper screw (a a), the india-rubber in a state of torsion (f) extends. By fixing the lower screw and turning the upper one a sufficient number of times the requisite degree of torsion and power is obtained. The apparatus when liberated flies into the air sometimes to a height of 30 ft., and gyrates in large circles for a period varying from 15 to 30 seconds.

Penaud next directed his attention to the construction of a model, to be propelled by a screw and sustained by an elastic aeroplane extending horizontally. Sir George Cayley proposed such a machine in 1810, and W. S. Henson constructed and patented a similar machine in 1842. Several inventors succeeded in making models fly by the aid of aeroplanes and screws, as, e.g. J. Stringfellow in 1847, and F. du Temple in 1857. These models flew in a haphazard sort of a way, it being found exceedingly difficult to confer on them the necessary degree of stability fore and aft, and laterally. Penaud succeeded in overcoming the difficulty in question by the invention of what he designated an automatic rudder. This consisted of a small elastic aeroplane placed aft or behind the principal aeroplane which is also elastic. The two elastic aeroplanes extended horizontally and made a slight upward angle with the horizon, the angle made by the smaller aeroplane (the rudder) being slightly in excess of that made by the larger. The motive power was india-rubber in the condition of torsion; the propeller, a screw. The reader will understand the arrangement by a reference to the accompanying drawing (fig. 39).

Models on the aeroplane screw type may be propelled by two screws, one fore and one aft, rotating in opposite directions; and in the event of only one screw being employed it may be placed in front of or behind the aeroplane.

When such a model is wound up and let go it descends about 2 ft., after which, having acquired initial velocity, it rises and flies in a forward direction at a height of from 8 to 10 ft. from the ground for a distance of from 120 to 130 ft. It flies this distance in from 10 to 11 seconds, its mean speed being something like 12 ft. per second. From experiments made with this model, Penaud calculates that one horse-power would elevate and support 85 lb.

D. S. Brown also wrote (1874) in support of elastic aeroplanes. His experiments proved that two elastic aeroplanes united by a central shaft or shafts, and separated by a wide interval, always produce increased stability. The production of flight by the vertical flapping of wings is in some respects the most difficult, but this also has been attempted and achieved. Penaud and A. H. de Villeneuve each constructed winged models. Marcey was not so fortunate. He endeavoured to construct an artificial insect on the plan advocated by Borelli, Strauss-Dürckheim and Chabrier, but signally failed, his insect never having been able to lift more than a third of its own weight.

De Villeneuve and Pенаud constructed their winged models on different types, the former selecting the bat, the latter the bird.

De Villeneuve made the wings of his artificial bat conical in shape and comparatively rigid. He controlled the movements of the wings, and made them strike downwards and forwards in imitation of natural wings. His model possessed great power of rising. It elevated itself from the ground with ease, and flew in a horizontal direction for a distance of 24 ft., and at a velocity of 20 m. an hour. Penaud’s model differed from de Villeneuve’s in being provided with elastic wings, the posterior margins of which in addition to being elastic were free to move round the

FLIGHT AND FLYING

The chief feature of the invention was the very great expanse of its sustaining planes, which were larger in proportion to the weight it had to carry than those of many birds. The machine advanced with its front edge a little raised, the effect of which was to present its under surface to the air over which it passed, the resistance of which, acting upon it like a strong wind on the sails of a windmill, presented the descent of the machine and its burden. The sustaining of the whole, therefore, depended upon the speed at which it travelled through the air, and the angle at which its under surface impinged on the air in its front... The machine, fully prepared for flight, was started from the top of an inclined plane, in descending which it attained a velocity necessary to sustain it in its further progress. That velocity would be gradually destroyed by the resistance of the air to the forward flight; it was, therefore, the office of the steam-engine and the vanes it actuated simply to repair the loss of velocity; it was made, therefore, only of the power and weight necessary for that small effect. The editor of Newton's Journal of Arts and Science speaks of it thus:--"The apparatus consists of a car containing the goods, passengers, engines, fuel, &c., to which a rectangular frame, made of wood or bamboo cane, and covered with canvas or oiled silk, is attached. This frame extends on either side of the car in a simple manner to the outstretched wings of a bird; but with this difference, that the frame is immovable. Behind the wings are two vertical fan wheels, furnished with oblique vanes, which are intended to propel the apparatus through the air. The rainbow-like circular wheels are the propellers, answering to the wheels of a steam-boat, and acting upon the air after the manner of a windmill. These wheels receive motions from bands and pulleys from a steam or other engine contained in the car. To an axis at the stern of the car a triangular frame is attached, resembling the tail of a bird, which is also covered with canvas or oiled silk. This may be expanded or contracted for the purpose of causing the machine to ascend or descend. Beneath the tail is a rudder for directing the course of the machine to the right or to the left, and to facilitate the steering a sail is stretched between two masts which rise from the car. The amount of canvas or oiled silk necessary for buoying up the machine is stated to be equal to one square foot for each half pound of weight."
propellers) was under 12 lb. Its sustaining area, if that of the tail (\(\delta\)) be included, was something like 36 sq. ft., i.e. 3 sq. ft. for every pound. The model was forced by its propellers along a wire at a great speed, but so far as an observer could determine, failed to lift itself, notwithstanding its extreme lightness and the comparatively very great power employed. Stringfellow, however, stated that it occasionally left the wire and was sustained by its aeroplanes alone.

The aerial steamer of Thomas Moy (fig. 45), designed in 1874, consisted of a light, powerful, skeleton frame resting on three wheels; a very effective light engine constructed on a new principle, which dispensed with the old-fashioned, cumbersome boiler; two long, narrow, horizontal aeroplanes; and two comparatively very large aerial screws. The idea was to get up the initial velocity by a preliminary run on the ground. This accomplished it was hoped that the weight of the machine would gradually be thrown upon the aeroplanes in the same way that the weight of certain birds—the eagle, e.g.—is thrown upon the wings after a few hops and leaps. Once in the air the aeroplanes, it was believed, would become effective in proportion to the speed attained. The machine, however, did not realize the high expectations formed of it, and like all its predecessors it was doomed to failure.

Two of the most famous of the next attempts to solve the problem of artificial flight, by means of aeroplanes, were those of Prof. S. P. Langley and Sir Hiram S. Maxim, who began their aerial experiments about the same time (1889-1890). By 1893-1894 both had embodied their views in models and large flying machines.

Langley, who occupied the position of secretary to the Smithsonian Institution, Washington, U.S.A., made many small flying models and one large one. These he designated "aerodromes." They were all constructed on a common principle, and were provided with extensive flying surfaces in the shape of rigid aeroplanes inclined at an upward angle to the horizon, and more or less fixed on the plan advocated by Henson. The cardinal idea was to force the aeroplanes (slightly elevated at their anterior margins) forwards, kite-fashion, by means of powerful vertical screw propellers driven at high speed—the greater the horizontal speed provided by the propellers, the greater, by implication, the lifting capacity of the aerodrome. The bodies, frames and aeroplanes of the aerodromes were strengthened by vertical and other supports, to which were attached aluminium wires to ensure absolute rigidity so far as that was possible. Langley aimed at great lightness of construction, and in this he succeeded to a remarkable extent. His aeroplanes were variously shaped, and were, as a rule, concavo-convex, the convex surface being directed upwards. He employed a competent staff of highly trained mechanics at the Smithsonian Institution, and great secrecy was observed as to his operations. He flew his smallest models in the great lecture room of the National Museum, and his larger ones on the Potomac river about 40 m. below Washington.

While Langley conducted his preliminary experiments in 1889, he did not construct and test his steam-driven flying models until 1893. These were made largely of steel and aluminium, and one of them in 1896 made the longest flight then recorded for a flying machine, namely, fully half a mile on the Potomac river. The largest aerodrome, intended to carry passengers and to be available for war purposes, was built to the order and at the expense of the American government, which granted a sum of $700 000 for its construction.

Langley's machine shown in fig. 46 was a working model, not intended to carry passengers. In configuration the body-portion closely resembled a mackerel. The backbone was a light but very rigid tube of aluminium steel, 15 ft. in length, and a little more than 2 in. in diameter. The engines were located in the portion of the framework corresponding to the head of the fish; they weighed 60 oz. and developed one horse-power. There were four boilers made of thin hammered copper and weighing a little more than 7 lb each; these occupied the middle portion of the fish. The fuel used was refined gasoline, and the extreme end of the tail of the fish was utilized for a storage tank with a capacity of one quart. There were twin screw propellers, which could be adjusted to different angles in practice, to provide for steering, and made 1700 revolutions a minute. The wings, or aeroplanes, four in number, consisted of light frames of tubular aluminium steel-covered with china silk. The pair in front were 42 in. wide and 40 ft. from tip to tip. They could be adjusted at different angles. The machine required to be dropped from a height, or a preliminary forward impetus had to be given to it, before it could be started. Fixity of all the parts was secured by a tubular mast extending upwards and downwards through a pipe of the craft, and from its extremities ran stays of aluminium wire to the tips of the aeroplanes and the end of the tubular backbone. By this trussing arrangement the whole structure was rendered exceedingly stiff.

In the larger aerodrome (fig. 47) the aeroplanes were concavo-convex, narrow, greatly elongated and square at their free extremities, the two propellers, which were comparatively very large, being placed amidships, so to speak. At the first trial of this machine, on the 7th of October 1903, just as it left the launching track it was jerked violently down at the front (being caught, as subsequently appeared, by the falling waves), and under the full power of its engine was pulled into the water, carrying with it its engineer. When the aerodrome came to the surface, it was found that while the front sustaining surfaces had been broken by their impact with the water, the rear ones were comparatively uninjured. At the second and last attempt, on the 8th of December 1903, another disaster, again due to the launching ways, occurred as the machine was leaving the track. This time the back part of the machine, in some way still unexplained, was caught by a portion of the launching car, which caused the rear sustaining surface to break, leaving the rear entirely without support,
and it came down almost vertically into the water. Darkness had come before the engineer, who had been in extreme danger, could aid in any way. Only the steersman, who had been warned to watch the boat closely, was able to raise the machine and to clear the paddle apart, and one of the tugs in its zeal to render assistance had fastened a rope to the frame of the machine in the reverse position from what it should have been attached, and had broken the frame entirely in two. Owing to lack of funds further work was not attempted (see Annual Report of the Smithsonian Institution, 1904, p. 122).

Sir Hiram S. Maxim, like Langley, employed a staff of highly skilled engineers. A large test machine (fig. 38) consisted of a platform, on which stood a large water-tube boiler. The number of consecutive aeroplanes arranged in tiers like shelves, each making a slight upward angle with the horizon, two very large vertical screws placed aft and propelled by steam engines, tanks for the storage of water, naptha, &c. The boiler was especially noteworthy. The water was contained in about 2000 bent copper tubes, only 1 in. in external diameter, heated by over 7000 gas jets arranged in rows. The fuel was naptha or gasoline. The steam could be cut off in half a minute. The steam-generating appliances, which weighed only 1000 lb. in all, were placed in the front of the machine. The motive power was provided by a pair of two-cylinder, compound engines, placed about 8 ft. from the ground, and about 6 ft. apart. Each of them was independently governed, and furnished together 363 horse-power in actual effect, an amount which, considering that their total weight was only 600 lb., gave the extraordinary efficiency of over 1 horse-power per lb. weight. The high-pressure and the low-pressure cylinders were 5 and 8 in. in diameter respectively, and the stroke was 12 in. When going at full speed these engines conferred 245 revolutions per minute on the propellers, which drove the machine 4000 ft. per hour. These were in appearance like two-bladed marine propellers except that they were square instead of rounded at the ends, and were broad and thin. They were built from overlapping strips of American pine, planed smooth and covered with glued canvas. They weighed 135 lb. each, the length of each blade being close upon 9 ft. and the width at the ends 5 ft. The pitch was 16 ft. They were carefully stayed by steel wires to their shafts, or the first revolution would have snapped them off short. The material of which the framework was built was thin steel tubing, exceedingly light. All the wires and ties were of the best steel, capable of standing a strain of 100 tons to the square inch. The body of the machine was oblong in shape, with the fore-part cut away like a water-chute boat, and a long counter at the stern over which the propellers revolved. It had canvas stretched all over it. High overhead, like a gigantic awning, was the slightly concavo-convex main aeroplane, tilted towards the front at an imperceptible angle, and stretched taut. Its area was 1400 sq. ft., increased by side wings to 2700 sq. ft. There were also side aeroplanes arranged in tiers, and large aeroplanes in front, which were pivoted and served for vertical steering. The machine was strengthened in every direction by vertical and other supports and securely wired together at all points. It was furnished with four strong flanged wheels and ran along a light broad-gauge (9 ft.) railway track. It was 1800 ft. long, in the hope that when the speed reached a certain point it would leave the rails, but it was prevented from rising more than an inch or so by four arms, or outriggers, furnished with wheels which projected from its sides and ran under an inverted wooden upper or safety track outside the railway track proper. At a trial carried out in 1894 at Bexley, Kent, only the main aeroplane, the fore and aft rudders, and the top and bottom side planes were in position. After everything had been got in readiness, careful observers were stationed along the track, and the machine was connected to a dynamometer. The engines were then started and the pump set so as to deliver over 5000 lb. of water per hour to the boiler. The gas was then carefully turned on until the pressure amounted to 310 lb. per sq. in., and the dynamometer showed a thrust of more than 2100 lb. A small safety-valve was placed in the steam, and the steam pressure had been adjusted so as to blow off slightly at 310 lb. and with a strong blast at 320 lb. The signal being given to let go, the machine darted forward at a terrific pace, and the safety-valve was forced to blow. From the moment the gas was instantly turned on, and before the machine had advanced 300 ft., the steam had mounted to 320 lb. per sq. in., and the safety-valve was blowing off a steady blast. When the machine had travelled about 2000 ft. the60 safety-valve, which had been engaged, was still blowing. It was lifted at least 8000 lb. The speed rapidly increased until when the machine had run about 900 ft. one of the rear axletrees, which were of 2 in. steel tubing, doubled up and set the rear end of the machine completely free. When the machine had travelled about 1000 ft., the left-hand forward wheel became disengaged from the safety track, and shortly after this the right-hand wheel broke the upper track—3 in. by 9 in. Georgia pine—and a plank became entangled in the framework of the machine. Steam had already been shut off, and the machine coming to rest fell directly to the ground, all four of its wheels sinking deeply into the turf without leaving other marks. Before making this run the wheels which were to engage the upper track were painted, and the paint left by them on the upper track indicated the exact point where the machine lifted. The area of the aeroplanes was very nearly 4000 sq. ft. and the total lifting effect was fully 10,000 lb. The planes therefore lifted 2-5 lb. per sq. ft., and 5 lb. for each pound thrust. Nearly half of the power of the engines was lost in the screw slip. This showed that the diameter of the screws was not great enough; it should have been at least 22 ft.

In 1897 M. C. Ader, who had already tested, with indifferent results, two full-sized flying machines, built a third apparatus with funds furnished by the French government. This reproduced the structure of a bird with almost servile imitation, save that traction was obtained by two screw-propellers. The steam engine weighed about 7 lb. per horse-power, but the equilibrium of the apparatus was defective.

Largely with the view of studying the problem of maintaining equilibrium, several experimenters, including Otto Lilienthal, Percy Pilcher and Octave Chanute, cultivated gliding flight by means of aeroplanes capable of sustaining a man. They depended mainly on the utilization of natural air currents, trusting for stability and balance to movements in their own bodies, or in portions of their machines which they could control. They threw themselves from natural or artificial elevations, or, facing the wind, they ran or were dragged forwards until they got under way and the wind caught hold of their aeroplanes.

To Lilienthal in Germany belongs the double credit of demonstrating the superiority of arched over flat surfaces, and of reducing gliding flight to regular practice. He made over 2000 glides safely, using gravity as his motive power, with concave, batlike wings, in some cases with superposed surfaces (fig. 49).
the main supporting aeroplanes as a means of maintaining the structure in proper balance. Their machines to begin with were merely gliders, the operator lying upon them in a horizontal position, but in 1903 a petrol motor was added, and a flight lasting 50 seconds was performed. In 1905 they made forty-five flights, in the longest of which they remained in the air for half an hour and covered a distance of 243 m. The utmost secrecy, however, was maintained concerning their experiments, and in consequence their achievements were regarded at the time with doubt and suspicion, and it was hardly realized that their success would reach the point later achieved.

Thanks, however, to the efforts of automobile engineers, great improvements were now being effected in the petrol engine, and, although the certainty and trustworthiness of its action still left something to be desired, it provided the designers of flying machines with what they had long been looking for—a motor very powerful in proportion to its weight. Largely in consequence of this progress, and partly no doubt owing to the stimulus given by the activity of builders of dirigible balloons, the construction of motor-driven aeroplanes began to attract a number of workers, especially in France. In 1906 A. Santos Dumont, after a number of successful experiments with dirigible cigar-shaped gas balloons, completed an aeroplane flying machine. It consisted of the following parts:—(a) A system of aeroplanes arranged like the capital letter T at a certain upward angle to the horizon and bearing a general resemblance to box kites; (b) a pair of very light propellers driven at a high speed; and (c) an exceedingly light and powerful petrol engine. The driver occupied a position in the centre of the arrangement, which is shown in fig. 52. The machine was furnished with two wheels and vertical supports which depended from the anterior parts of the aeroplanes and supported it when it touched the ground.

FIG. 51.—Chanute's Biplane Gliding Machine.

on either side. With this apparatus he traversed on the 12th of November 1906 a distance of 230 metres in 21 seconds.

About a year later Henry Farman made several short flights on a machine of the biplane type, consisting of two main supporting surfaces one above the other, with a box-shaped vertical rudder behind and two small balancing aeroplanes in front. The engine was an eight-cylinder Antoinette petrol motor, developing 49 horse-power at 1100 revolutions a minute, and driving directly a single metal screw propeller. On the 27th of October 1906 he flew a distance of nearly half a mile at Issy-les-Molines, and on the 15th of January 1908 he made a circular flight of one kilometre, thereby winning the Deutsch-Archdeacon prize of £2000. In March he remained in the air for 33 minutes, covering a distance of 74 m.; but in the following month a rival, Leon Delagrange, using a machine of the same type and constructed by the same makers, Messrs Voisin, surpassed this performance by flying nearly 24 m. in 65 minutes. In July Farman remained in the air for over 20 minutes; on the 6th of September Delagrange increased the time to nearly 30 minutes, and on the 29th of the same month Farman again came in front with a flight lasting 42 minutes and extending over nearly 244 m.

But the best results were obtained by the Wright brothers—Orville Wright in America and Wilbur Wright in France. On the 9th of September 1908 the former, at Fort Myers, Virginia, made three notable flights; in the first he remained in the air 574 minutes and in the second 1 hour 3 minutes, while in the third he took with him a passenger and covered nearly 4 m. in 6 minutes. Three days later he made a flight of 45 m. in 1 hour 14½ minutes, but on the 17th he had an accident, explained as being due to one of his propellers coming into contact with a stay, by which his machine was wrecked, he himself seriously injured, and Lieutenant Selfridge, who was with him, killed. Four days afterwards Wilbur Wright at Le Mans in France beat all previous records with a flight lasting 1 hour 31 minutes 25½ seconds, in which he covered about 56 m.; and subsequently, on the 11th of October, he made a flight of 1 hour 9 minutes accompanied by a passenger. On the 31st of December he succeeded in remaining in the air for 2 hours 20 minutes 23 seconds.

Wilbur Wright's machine (fig. 53), that used by his brother being essentially the same, consisted of two slightly arched supporting surfaces, each 123 metres long, arranged parallel one above the other at a distance of 1½ metres apart. As they were each about 2 metres wide their total area was about 50 sq. metres. About 3 metres in front of them was arranged a pair of smaller horizontal aeroplanes, shaped like a long narrow ellipse, which formed the rudder that effected changes of elevation, the driver being able by means of a lever to incline them up or down according as he desired to ascend or descend. The rudder for lateral steering was placed about 2½ metres behind the main surfaces and was formed of two vertical pivoted aeroplanes. The lever by which they were turned was connected with the device by which the ends of the main aeroplanes could be flexed simultaneously though in opposite directions; i.e. if the ends of the aeroplanes on one side were bent downwards, those on the

other were bent upwards. By the aid of this arrangement the natural cant of the machine when making a turn could be checked, if it became excessive. The four-cylinder petrol engine was placed on the lower aeroplane a little to the right of the central line, being counterbalanced by the driver (and passenger

if one was carried), who sat a little to the left of the same line. Making about 1300 revolutions a minute, it developed about 24 horse-power, and was connected by chain gearing to two wooden propellers, 2½ metres in diameter and 3½ metres apart, the speed of which was about 450 revolutions a minute. The whole machine, with aeronaut, weighed about 1100 lb, the weight of the motor being reputed to be 200 lb.

A feature of the year 1900 was the success obtained with monoplanes having only a single supporting surface, and it was on a machine of this type that the Frenchman Blériot on July 25th flew across the English Channel from Calais to Dover in 31 minutes. Hubert Latham all but performed the same feat on an Antoinette monoplane. The year saw considerable increases in the periods for which aviators were able to remain in the air, and Roger Sommer's flight of nearly 2½ hours on August 7th was surpassed by Henry Farman on November 3rd, when he covered a distance estimated at 137½ mi. in 4 hr. 17 min. 53 sec. In both these cases biplanes were employed. Successful aviation meetings were held, among other places, at Reims, Juvissy, Doncaster and Blackpool; and at Blackpool a daring flight was made in a wind of 40 m. an hour by Latham. This aviator also proved the possibility of flying at considerable altitudes by attaining on December 1st a height of over 1900 ft., but this record was far surpassed in the following January by L. Paulhan, who on a biplane rose to a height of 1385 yds. at Los Angeles. In the course of the year three aviators were killed—Lefèvre and Ferber in September and Fernandez in December; and four men perished in September by the destruction of the French airship "République," the gas-bag of which was ripped open by a broken propeller. In January 1910 Delagrange was killed by the fracture of one of the wings of a monoplane on which he was flying. On April 27th-28th, 1910, Paulhan successfully flew from London to Manchester, with only one stop, within 24 hours, for the Daily Mail's £10,000 prize.

The progress made by all these experiments at aviation had naturally created widespread interest, both as a matter of sport and also as indicating a new departure in the possibilities of machines of war. And in 1909 the British government appointed a scientific committee, with Lord Rayleigh as chairman, as a consultative body for furthering the development of the science in England.

The table below gives some details, approximately correct, of the principal experiments made with flying machines up to 1908.

*The apparatus marked thus * carried a man or men.
received the stadtholder John Maurice, whose portrait is still preserved in the work of the learned Barleius.

The earliest of Flinck's authentic pieces is a likeness of a lady, dated 1616, in the gallery of Brunswick. His first subject picture is the "Blessing of Jacob," in the Amsterdam museum (1638). Both are thoroughly Rembrandtseque in effect as well as in vigour of touch and warmth of flesh tints. The four "civic guards" of 1642, and the "twelve musketeers" with their president in an arm-chair (1648), in the town-hall at Amsterdam, are fine specimens of composed portrait groups. But the best of Flinck's productions in this style is the peace of Münster in the museum of Amsterdam, a canvas with 19 life-size figures full of mimicry and wit. Among the civic guards and the "Greyc Beard boy" of 1639 in Dresden, the "Girl" of 1641 at the Louvre, a portrait group of a male and female (1646) at Rotterdam, a lady (1651) at Berlin. In November 1659 the burgher-master of Amsterdam contracted with Flinck for 12 canvases to represent four heroic figures of David and Samson and Marcus Curius and Horatius Cocles, and scenes from the wars of the Batavians and Romans. Flinck was unable to finish more than the sketches. In the same year he received a flattering acknowledgment from the town council of Cleves on the completion of a picture of Solomon which was a counterpart of the composition at Amsterdam. This and other pictures and portraits, such as the likenesses of Frederick William of Brandenburg and John Maurice of Nassau, and the allegory of "Louisa of Orange attended by Victory and Fame" and other figures at the cradle of the first-born son of the elector, have disappeared. Of several pictures which were painted for the Great Elector, none are preserved except the "Expulsion of Hagar" in the Berlin museum. Flinck died at Amsterdam on the 22nd of February 1660.

FLINDERS, MATTHEW (1774-1814), English navigator, explorer, and man of science, was born at Donington, near Boston, in Lincolnshire, on the 10th of March 1774. Matthew was at first designed to follow his father's profession of surgeon, but his enthusiasm in favour of a life of adventure impelled him to enter the royal navy, which he did on the 23rd of October 1795. After a voyage to the Friendly Islands and West Indies, and after serving in the "Bellerophon" during Lord Howe's "glorious first of June" (1794) off Ushant, Flinders went out in 1795 as midshipman in the "Reliance" to New South Wales. For the next few years he devoted himself to the task of accurately laying down the outline and bearings of the Australian coast, and he did his work so thoroughly that he left comparatively little for his successors to do. With his friend George Bass, the surgeon of the "Reliance," in the year of his arrival he explored George's river; and, after a voyage to Norfolk Island, again in March 1796 the two friends in the same boat, the "Tom Thumb," only 8 ft. long, and with only a boy to help them, explored a stretch of coast to the south of Port Jackson. After a voyage to the Cape of Good Hope, when he was promoted to a lieutenantcy, Flinders was engaged during February 1797 in a survey of the Furneaux Islands, lying to the north of Tasmania. His delight was great when, in September of the same year, he was commissioned along with Bass, who had already explored the sea between Tasmania and the south coast to some extent and inferred that it was a strait, to proceed in the sloop "Norfolk" (25 tons) to prove conclusively that Van Diemen's Land was an island by circumnavigating it. In the same sloop, in the summer of next year, Flinders made an exploration to the north of Port Jackson, the object being mainly to survey Glasshouse Bay (Moreton Bay) and Hervey's Bay. Returning to England he was appointed to the command of an expedition for the thorough exploration of the coasts of Terra Australis, as the southern continent was still called, though Flinders is said to have been the first to suggest for it the name Australia. On the 18th of July 1801 the sloop "Investigator" (334 tons), in which the expedition sailed, left Spithead, Flinders being furnished with instructions and with a passport from the French government to all their officials in the Eastern seas. Among the scientific staff was Robert Brown, one of the most eminent English botanists; and among the midshipmen was Flinders's relative, John Franklin, of Arctic fame. Cape Leeuwin, on the southwest coast of Australia, was reached on November 6, and King George's sound on the 9th of December. Flinders sailed round the Great Bight, examining the islands and indentations on the east side, noting the nature of the country, the people, products, &c., and paying special attention to the subject of the variation of the compass. Spenser and St Vincent Gulfs were discovered and explored. On the 8th of April 1802, shortly after leaving Kangaroo Islands, at the mouth of St Vincent Gulf, Flinders fell in with the French exploring ship, "Le Geographe," under Captain Nicolas Baudin, in the bay now known as Encounter Bay. In the navigators of Australia. Flinders was 1807 (when Flinders was a prisoner in the Mauritius) by M. Peron, the naturalist to the expedition, much of the land west of the point of meeting was claimed as having been discovered by Baudin, and French names were extensively substituted for the English ones given by Flinders. It was only in 1814, when Flinders published his own narrative, that the real state of the case was fully exposed. Flinders continued his examination of the coast along Bass's Strait, carefully surveying Port Phillip. Port Jackson was reached on the 9th of May 1802. After staying at Port Jackson for about a couple of months, Flinders set out again on the 22nd of July to complete his circumnavigation of Australia. The Great Barrier Reef was examined with the greatest care in several places. The north-east entrance of the Gulf of Carpentaria was reached early in November; and the next three months were spent in an examination of the shores of the gulf, and of the islands that skirt them. An inspection of the "Investigator" showed that she was in so leaky a condition that only with the greatest precaution could the voyage be completed in her. Flinders completed the survey of the Gulf of Carpentaria in October. At the island of Timor, the "Investigator" sailed round the west and north coast of Australia, and Port Jackson was reached on the 9th of June 1803. Much suffering was endured by nearly all the members of the expedition: a considerable proportion of the men succumbed to disease, and their leader was so reduced by scurvy that his health was greatly impaired.

Flinders determined to proceed home in H.M.S. "Porpoise" as a passenger, submit the results of his work to the Admiralty, and obtain, if possible, another vessel to complete his exploration of the Australian coast. The "Porpoise" left Port Jackson on the 8th of August, accompanied by the H.E.I.C.'s ship "Bridge-water" (750 tons) and the "Cato" (450 tons) of London. On the night of the 17th the "Porpoise" and "Cato" suddenly struck on a coral reef and were rapidly reduced to wrecks. The officers and men encamped on a small sandbank near, 3 or 4 f. above high-water, a considerable quantity of provisions, with many of the papers and charts, having been saved from the wrecks. The reef was in about 22° 11' S. and 155° E., and about 800 m. from Port Jackson. Flinders returned to Port Jackson in a sloop, the same in April to obtain a vessel to continue the party. The reef was again reached on the 8th of October, and all the officers and men having been satisfactorily disposed of, Flinders on the 11th left for Jones Strait in an unsound schooner of 29 tons, the "Cumberland," with ten companions, and a valuable collection of papers, charts, geological specimens, &c. On the 15th of December he put in at Mauritius, when he discovered that France and England were at war. The passport he possessed from the French government was for the "Investigator"; still, though he was now on board another ship, his mission was
essentially the same, and the work he was on was simply a continuation of that commenced in the unfortunate vessel. Nevertheless, on her arrival at Port Louis the “Cumberland” was seized by order of the governor-general de Caen. Flinders’s papers were taken possession of, and he found himself virtually a prisoner. We need not dwell on the sad details of this unjustifiable captivity, which lasted to June 1810. But there can be no doubt that the hardships and inactivity Flinders was compelled to endure for upwards of six years told seriously on his health, and brought on his premature end. He reached England in October 1816, after an absence of upwards of nine years. The official red-tape of the day barred all promotion to the unfortunate explorer, who set himself to prepare an account of his explorations, though unfortunately an important part of his record had been retained by de Caen. The results of his labours were published in two large quarto volumes, entitled A Voyage to Terra Australis, with a folio volume of maps. The very day (July 19, 1814) on which his work was published Flinders died, at the early age of forty. The great work is a model of its kind, containing as it does not only a narrative of his own and of previous voyages, but masterly statements of the scientific results, especially with regard to magnetism, meteorology, hydrography and navigation. Flinders paid great attention to the errors of the compass, especially to those caused by the presence of iron in ships. He is understood to have been the first to discover the source of such errors (which had scarcely been noticed before), and after investigating the laws of the variations, he suggested counter-attributions, an invention for which Professor Barlow got much credit many years afterwards. Numerous experiments on ships’ magnetism were conducted at Portsmouth by Flinders, by order of the admiralty, in 1812. Besides the Voyage, Flinders wrote Observations on the Coast of Van Diemen’s Land, Bass’s Strait, &c., and two papers in the Phil. Trans.—one on the “Magnetic Needle” (1805), and the other, “Observations on the Marine Barometer” (1806).

FLINSBERG, a village and watering-place of Germany, in the Prussian province of Silesia, on the Queis, at the foot of the Isenkarm, 1450 ft. above the sea, 5 m. W. of Friedeburg, the terminus station of the railway from Greifenburg. Pop. (1900) 1857. It contains an Evangelical and a Roman Catholic church, and has some manufactures of wooden wares. Flinsberg is celebrated for its chalybeate waters, specific in cases of feminine disorders, and used both for bathing and drinking. It is also a climatic health resort of some reputation, and the visitors number about 8000 annually.

See Adam, Bad Flinsberg als klimatischer Kurort (Göriltz, 1891).

FLINT, AUSTIN (1812–1886), American physician, was born at Framingham, Massachusetts, on the 20th of October 1812, and graduated at the medical department of Harvard University in 1833. From 1827 to 1832 he was professor of the theory and practice of medicine in Buffalo Medical College, of which he was one of the founders, and from 1832 to 1836 he filled the same chair in the university of Louisville. From 1836 to 1838 he was professor of the principles and practice of medicine and clinical medicine in Bellevue Hospital Medical College, New York. He wrote many textbooks on medical subjects, among them Diseases of the Heart (1855–1857); Principles and Practice of Medicine (1866); Clinical Medicine (1870); and Physical Exploration of the Lungs by means of Auscultation and Percussion (1882). He died in New York on the 13th of March 1886.

His son, AUSTIN FLINT, jun., who was born at Northampton, Massachusetts, on the 28th of March 1836, after studying at Harvard and at the university of Louisville, graduated at the Jefferson Medical College, Philadelphia, in 1857. He then became professor of physiology at the university of Buffalo (1858) and subsequently at other places, his benefaction being with the Cornell University Medical College (1898–1906). He was better known as a teacher and writer on physiology than as a practitioner, and his Text-book of Human Physiology (1876) was for many years a standard book in American medical colleges. He also published an extensive Physiology of Man (5 vols., 1856–1874), Chemical Examination of the Urine in Disease (1870), Effects of Severe and Protracted Muscular Exercise (1871), Source of Muscular Power (1878), and Handbook of Physiology (1905). In 1896 he became a consulting physician to the New York State Hospital for the Insane.

FLINT, ROBERT (1838–1914), Scottish divine and philosopher, was born near Dumfries and educated at the university of Glasgow. After a few years of pastoral service, first in Ayr and then at Kilconquhar, Fife, he was appointed professor of moral philosophy and political economy at St Andrews in 1864. From 1870 to 1900 he was professor of divinity at Edinburgh. He contributed a number of articles to the 9th edition of the Encyclopaedia Britannica. His chief works are Christ’s Kingdom upon Earth (Sermons, 1865); Philosophy of History in Europe (1874; partly rewritten with reference to France and Switzerland, 1894); Theism and Anti-Theistic Theories (2 vols., being the Baird Lectures for 1876–1877; often reprinted); Socialism (1864); Sermons and Addresses (1890); Aestheticism (1903).

FLINT, TIMOTHY (1780–1840), American clergyman and writer, was born in Reading, Massachusetts, on the 11th of July 1780. He graduated at Harvard in 1800, and in 1802 settled as a Congregational minister in Lunenburg, Mass., where he pursued scientific studies with interest; and his labours in his chemical laboratory seemed so strange to the people of that retired region, that some persons supposed and asserted that he was engaged in counterfeiting. This, together with political differences, led to disagreeable complications, which resulted in his resigning his charge (1814) and becoming a missionary (1815) in the valley of the Mississippi. He was also for a short period a teacher and a farmer. His observations on the manners and character of the settlers of the Ohio and Mississippi valleys were recorded in a picturesque work called Recollections of the Last Ten Years passed in the Valley of the Mississippi (1826; reprinted in England and translated into French), the first account of the western states which brought to light the real life and character of the people. The success which this work met with, together with the failing health of the writer, led him to relinquish his more active labours for literary pursuits, and, besides editing the Western Review in Cincinnati from 1825 to 1828 and Knickerbocker’s Magazine (New York) in 1833, he published a number of books, including Francis Berrian, or the Mexican Patriot (1826), his best novel; A Condensed Geography and History of the Western States, or the Mississippi Valley (2 vols., 1828); Arthur Clennin (1828), a novel; and Indian Wars in the West (1833). His style is vivid, plain and forcible, and his matter interesting; and his works on the western states are of great value. He died in Salem, Mass., on the 16th of August 1840.

FLINT, a city and the county-seat of Genesee county, Michigan, U.S.A., on Flint river, 68 m. (by rail) N.W. of Detroit. Pop. (1890) 9820; (1900) 13,103, of whom 2165 were foreign-born; (1910, census) 38,550. It is served by the Grand Trunk and the Pere Marquette railways, and by an electric line, the Detroit United railway, connecting with Detroit. The city has a fine court-house (1904), a federal building (1908), a city hall (1908) and a public library. The Michigan school for the deaf, established in 1854, and the Oak Grove hospital (private) for the insane, are among the institutions of the city of national importance. It has also important manufacturing interests, its chief manufactures being automobiles, wagons, carriages—Flint is called "the vehicle city,"—flour, woolen goods, iron goods, cigars, beer, and bricks and tiles; and its grain trade is of considerable importance. In 1904 the total value of the city’s factory product was $6,177,170, an increase of 31.1 % over that of 1900. The settlement of the place, then called the Grand Traverse of the Flint, began in 1820, but Flint’s growth was very slow until 1851, when it was platted as a village; it was chartered as a city in 1855.

FLINT, or FLINTSHIRE (st Gallestr), a county of North Wales, the smallest in the country, bounded N. by the Irish Sea and the Dee estuary, N.E. by the Dee, E. by Cheshire, and S.W. by Denbighshire. Area, 2573 sq. m. Included in Flint is the detached hundred of Maerdy, lying 8 m. S.E. of the main part of the county,
and shut in by Cheshire on the N. and N.E., by Shropshire on the S., and by Denbighshire on the W. and N.W. The Clwyd valley is common to Flint and Denbigh. Those of the Alyn and Wepre (from Ewloe Castle to the Dee) are fine. The Dee, entering the county near Overton, divides Maenor from Denbigh on the W., passes Chester and bounds most of the county on the N. The Clwyd enters Flint near Bodfari, and joining the Elwy near Rhuddlan, reaches the Irish Sea near Rhyll. The Alyn enters the county under Moel Famau, passes Cisien and Mold (y Wyldegrug), runs underground near Hesh-Allyn (Alyn's drying-up), bends south to Caergwrle, re-enters Denbighshire and joins the Dee. Lyn Helyg (willow-pool), near Whitford, is the chief lake.

Both for their influence upon the physical features and for their economic value the carboniferous rocks of Flintshire are the most important. From Prestatyn on the coast a band of carboniferous limestones run north and south, the chief ones being by Caergwrle, at the Halkin Mountain east of Halkin, whence it continues past Mold to beyond the county boundary. The upper portion of this series is cherty in the north—the chert is quarried for use in the potteries of Staffordshire—but traced southward passes into thin grits; above these beds come the holywell shales, possibly the equivalent of the Pendleside series of Lancashire and Derbyshire, which, in their turn, pass upwards into the coal-measures of Flintshire. The older rocks have been compared to the Gannister coal measures of Lancashire, but may be a representative of the Millstone Grit. Farther to the east, the coal measures, with valuable coals, some oil shale, and with fireclays and ironstone, appear for both mining and building. Relying on Talacre through Flint, Northop, Hawarden and Broughton to Hope. The carboniferous rocks appear again through the intervention of a fault, in the neighbourhood of St Asaph. Silurian strata, mostly of Westphalian date, run across the carboniferous limestone of the upper part of the county, and the Triaclis red beds of the upper Silurian are in question. In the same formation, at Caer Gwyn and Ffynnnon Beuno, have yielded the remains of Pleistocene mammals along with paleolithic implements. Much glacial drift obscures the older rocks on the east and north and the valleys of the Clwyd. Short stretches of blown sand occur on the coast near Rhyll and Talacre.

The London & North Western Railway follows the coast-line. Other railways which cross the county are the Great Western, and the Wrexham, Mold & Connah's Quay, acquired by the Great Central company. For pasture the vale of Clwyd is well known. Many dairy produce by the undulating surfaces of Flintshire. Stock and dairy farming prosperous, native cattle being crossed with Hereford and Downs, native sheep with Leicesters and Southdowns, while in the thick mining population a ready market is found for meat, cheese, butter, &c. The population (81,700 in 1901) nearly doubled in the 19th century, and Flintshire to-day is one of the most densely populated counties in North Wales. The area of the ancient county is 164,744 acres, and that of the administrative county 163,023 acres. The collieries begin at Llanasa, run through Caergwrle, Holywell, Flint, Halkin (Henlyn), Northop, Buckley, Mold and Hawarden (Pepalad). At Halkin, Mold, Holywell, Prestatyn and Talacre lead is raised, and is sometimes sent to Bagillt, Flint or Chester to be smelted. Zinc, formerly only worked at Dyserth, has increased in output, and copper mines also exist, as at Talargoch, together with smelting and chemical works, oil, vitriol, potash and alkali manufactories. Potteries around Buckley send their produce chiefly to Connah's Quay, whence a railway crosses the Dee to the Birkenhead (Cheshire) district. Iron scows are now thin, but limestone quarries yield building stone, lime for burning and small stone for chemical works. Fisheries are unproductive and textile manufactures small.

The county returns one member to parliament. The parliamentary borough district (returning one member), consists of Caergwrle, Caerwys, Flint, Holywell, Mold, Overton, St Asaph and Rhuddlan. In addition, there is a small part of the Chester parliamentary borough. There is one municipal borough, Flint (pop. 4625). The other urban districts are: Buckley (5780), Connah's Quay (3360), Holywell (1852), Mold (4163), Prestatyn (4260) and Rhyll (8473). Flint is in the North Wales and Chester circuit, assizes being held at Mold. The Flint borough has a separate commission of the peace, but no separate court of quarter sessions. The ancient county, which is in the dioceses of Chester, Lichfield and St Asaph, contains forty-six entire ecclesiastical parishes and districts, with parts of eleven others.

Among sites of antiquarian or historical interest, besides the fragmentary ruin of Flint Castle, the following may be mentioned:—Caerwys, near Flint, still shows traces of Roman occupation. Bodfari (Bodfari) was traditionally occupied by the Romans. Moel y gaer (bald hill of the fortress), near Northop, is a remarkably perfect old British post. Maes y Garmon (perhaps for Meusdug Garmon, as y, the article, has no significance before the proper name, and so to be translated, battlefields of Germanus). A mile from Mold is the reputed scene of une victoire sans larmes, gagne non par les armes, mais par la foi (E. H. Vollet). The Britons, says the legend, were threatened by the Picts and Saxons, at whose approach the Alleudius of that Easter (a.d. 430) was sung. Panic duly seized the invaders, but the victor, St Germanus, confessor and bishop of Auxerre (a.d. 380-445), had to return to the charge in 446. He has, under the name Garmon, a great titular share in British topography. At Bangor Iscoed, "the great high choir in Maclor," was the monastery, destroyed with over 2000 monks, by Ethelfred of Northumberland in 667, as (by a curious coincidence) its namesake Bangor in Ireland was sacked by the Danes in the 9th century. Bede says (ii. 2) that Bangor monastery was in seven sections, with three hundred (working) monks. The supposed lines of direction of Watt's and Offa's dykes were: Basingwerk, Halkin, Hope, Alyn valley, Oswestry (Cross Oswelli, "Oswald's cross"), for Watt's, and Prestatyn, Mold, Minera, across the Severn (Hafren, or Sabrina) for Offa's. Owain Gwynedd (Gwynned or Venedoc, is North Wales) defeated Henry II. at Coed Ewloe (where is a tower) and at Coleshill (Cynsilly). Nearly Pant asa (pan is a bottom) is the medieval Maen Achwynfan (achwyn, to complain, maen, stone), and tumuli, menhirs (meini hirion) and inscribed stones are frequent throughout the county. There is a 14th-century cross in Newmarket churchyard. Caergwrle Castle seems early Roman, or even British; but most of the castles in the county date from the early Edwards.

FLINT, a municipal borough and the county town of the above; a seaport and contributory parliamentary borough, on the south of the Dee estuary, 192 m. from London by the London & North-Western railway. Pop. (1901) 4165. The seat of great alkali manufactures, it imports chiefly sulphur and other chemicals, exporting coal, soda, potash, copper, &c. The county gaol here, as at Haverfordwest, occupied an angle of the castle, was removed to Mold, and is now Chester Castle (jointly with Cheshire).

Flint Castle was built on a lonely rock by the riverside by Edward I. Here met Edward II. and Piers Gaveston. Edward III. bestowed its constabulary upon the earls of Chester, and here Richard II. surrendered to Bolingbroke. It was twice taken, after siege, by the parliamentarians, and finally dismantled in 1647. There remain a square court (with angle towers), round tower and drawbridge, all three entrusted to a constable, appointed by the crown under the Municipal Corporations Reform Act. Made a borough by Edward I., Flint was chartered by Edward III., and by Edward the Black Prince, as earl of Chester.

FLINT (a word common in Teutonic and Scandinavian languages, possibly cognate with the Gr. Φιλτρον, a tile, in petrology, a dark grey or dark brown crypto-crystalline substance which has an almost vitreous lustre, and when pure appears structureless to the unaided eye. In the mass it is dark and opaque, but thin plates or the edges of splinters are pale yellow and translucent. Its hardness is greater than that of steel, so that a knife blade leaves a grey metallic streak when drawn across its surface. Its specific gravity is 2.6 or only a little less than that of crystalline quartz. It is brittle, and when struck with a hammer it breaks up into almost perfect cubes. The fracture is perfectly conchoidal, so that blows with a hammer detach flakes which have convex, slightly undulating surfaces. At the point of impact a bulb of percussion, which is a somewhat
FLINT IMPLEMENTS AND WEAPONS

FLINT IMPLEMENTS AND WEAPONS. The excavation of these remains of the prehistoric races of the globe in river-drift gravel-beds has marked a revolution in the study of Man’s history (see Palaeolithic). Until almost the middle of the present century no suspicion had arisen in the minds of British and European archaeologists that the momentous results of the excavations then proceeding in Egypt and Assyria would be dwarfed by discoveries at home which revolutionized all previous ideas of Man’s antiquity. It was in 1847 that Boucher de Perthes observed in some sand containing mammal remains, at Menchecourt near Abbeville, a flint, roughly worked into a cutting instrument. This “find” was rapidly followed by others, and Boucher de Perthes published his first work on the subject. Antiquités celtiques et antédiluviennes: mémoire sur l’Industrie primitive et les arts à leur origin (1847), in which he proclaimed his discovery of human weapons in beds unmistakably belonging to the age of the Drift. It was not until 1859 that the French archaeologist convinced the scientific world. An English mission then visited his collection and testified to the great importance of his discoveries. The “finds” at Abbeville were followed by others in many places in England, and in fact in every country of Europe which has had发现了 those streets of stones which are capable of being flaked and fashioned into implements are to be found. And the implements occurred in beds of rivers and lakes, in the tumuli and ancient burial-mounds; on the sites of settlements of prehistoric man in nearly every land, such as the shell-heaps and lake-dwellings; but especially embedded in the high-level gravels of England and France which have been deposited by river-flows and long left high and dry above the present course of the stream. These gravels represent the Drift or Palaeolithic period when man shared Europe with the mammoth and woolly-haired rhinoceros. The worked flints of this age are, however, unevenly distributed; for while the river-gravels of south-eastern England yield them abundantly, none has been found in Scotland or the northern English counties. On the continent the same partial distribution is observable: while they occur plentifully in the north-western area of France, they are not discovered in Sweden, Norway or Denmark. The association of these flints, fashioned for use by chipping only, with the bones of animals either extinct or no longer indigenous, has justified their reference to the earlier period of the Stone Age, generally called Palaeolithic. These flint implements, which show signs of polishing and in many cases remarkably fine workmanship, and are found in tumuli, peat-bogs and lake-dwellings mixed with the bones of common domestic animals, are assigned to the Neolithic or later Stone Age. The Palaeolithic flints are hammers, flakes, scrapers, implements worked to a cutting edge at one side, implements which resemble rude axes, that ovoid implements worked to an edge all round, and a great quantity of spear and arrow heads. None of these is ground or polished. The Neolithic flints, on the other hand, exhibit more variety of design, are carefully finished, and the particular use of each weapon can be easily detected. Man has reached the stage of culture when he could socket a stone into a wooden handle, and fix a flaked flint as a handled dagger or knife. The workmanship is superior to that shown in any of the stone utensils made by savage tribes of historic times. The manner of making flint implements appears to have been in all ages much the same. Flint from its mode of fracture is the only stone which can be chipped or flaked into almost any shape, and thus forms the principal material of these earliest weapons. The blows must be carefully aimed or the flakes

elevated conical mark, is produced. This serves to distinguish flints which have been fashioned by human agencies from those which have been split merely by the action of frost and the weather. The bulb is evidence of a direct blow, probably intended, and is a point of some importance to archaeologists investigating Palaeolithic implements. With skill and experience a mass of flint can be worked to any simple shape by well directed strokes, and further trimming can be effected with pressure by a pointed stone in a direction slightly across the edge of the weapon. The purest flints have the most perfect conchoidal fracture, and prehistoric man is known to have quarried or mined certain bands of flint which were specially suitable for his purposes.

Silica forms nearly the whole substance of flint; calcite and dolomite occur in small amounts, and analysis has also detected minute quantities of volatile ingredients, organic compounds, &c., to which the dark colour is ascribed by some authorities. These are dissolved by heat and the flint becomes white and dull in lustre. Microscopic sections show that flint is very finely crystalline and consists of quartz or chalcedonic silica; colloidal or amorphous silica may also be present but cannot form any considerable part of the rock. Speculars of sponges and fragments of other organisms, such as molluscs, polychaeta, foraminifera and brachiopods, often occur in flint, and may be partly or wholly silicified with retention of their original structure. Such flint is removed as gravel, shaped and polished by the flowing water, and is often afterwards continued, by the action of waves, to form coprolites. The nature of this deposit has been much disputed. It has been suggested that this change is due to the removal of the colloidal silica in solution, leaving behind the fibres and grains of more crystalline structure. This process must be a slow one, if applied to the chemical constitution, flint is a material of great durability. Its great hardness also enables it to resist attrition. Hence on beaches and in rivers, such as those of the south-east of England, flint pebbles exist in vast numbers. Their surfaces are often show minute crescentic or rounded cracks which are the edges of small conchoidal fractures produced by the impact of one pebble on another during storms or floods. These may be covered for instance as concretions, veins and tabular masses in the white chalk of such localities as the south of England (see Chalk). It is generally nodular, and forms rounded or highly irregular masses which may weigh several feet in diameter. Although the flint nodules often lie in beds which closely follow the bedding, they were not deposed simultaneously with the chalk; very often the flint bands cut across the beds of the limestone and may traverse them at right angles. Evidently the flint has accumulated along fissures, such as bedding planes, joints and other cracks, after the chalk had to some extent consolidated. The silica was derived from the tests of radiolaria and the siliceous skeletons of other organic remains. It has been suggested that the flint may have been deposited on the chalk, but it is more likely that it became separated from the chalk by the operation of metasomatic replacement in which a siliceous rock has slowly replaced a calcareous one. The process has been very gradual and the organisms of the original chalk often have their outlines preserved in it. They may become entirely silicified, or may leave their cavities occupied by flint with every detail of the interior of the shell preserved in the outer surface of the cast. Objects of this kind are familiar to all collectors of fossils in chalk districts.

Chert is a coarser and less perfectly homogeneous substance of the same nature and composition as flint. It is grey, black or brown, and commonly occurs in limestone (e.g. the Carboniferous Limestone) in the same way as flint occurs in chalk. Some cherts contain tests of radiolaria, and correspond fairly closely to the siliceous radiolarian oozes which are gathering at the present day at the bottom of some of the deepest parts of the ocean. But although some cherts are found in the English Greensand, these often contain remains of sponges.

The principal uses to which flint has been put are the fabrication of weapons in Palaeolithic and Neolithic times. Other material, such as obsidian, chert, chalcedony, agate and quartzite, but to prehistoric man (see Flint Implements below) flint must have been of great value and served many of the uses to which steel is put at the present day. Flint gravels are widely employed for dressing walks and roads, and for rough-cast work in architecture. For road-mending flint, though very hard, is not regarded with favour, as it is brittle and pulverizes readily, and it is well known that the surface which breaks up is rough, and very destructive to traffic and in bad weather; and its fine sharp-edged chips do much damage to tires of motors and cycles. Seasoned flints from the land, having been long exposed to the atmosphere, are preferred to flints freshly dug from the chalk pits. Formerly flint and steel were everywhere employed for striking a light; and gun flints were required for fire-arms. A special industry in the shaping of gun-flints long existed at Brandon in Suffolk. In 1879 about thirty men were employed. Since then the trade has become almost extinct as gun flints are in demand only in semi-savage countries where modern fire-arms are not obtainable. Powdered flint was formerly used in the manufacture of gunpowder, and is still one of the ingredients of many of the finer varieties of pottery.
diolodged would be shattered: a gun-flint maker at Brandon, Suffolk, stated that it took him two years to acquire the art.

For accounts of the gun-flint manufacture at Brandon, and detailed descriptions of ancient flint-working, see Sir John Evans, _Ancient Stone Implements_ (1867), Lord Avebury's _Prehistoric Times_ (1865, 1900); also Thomas Wilson, "Arrow-heads, Spear-heads and Knife-stones," _Archaeological Journal_ for 1857; and W. K. Moorehead, _Prehistoric Implements_ (1900).

FLOAT (in O. Eng. _float_ and _flota_, in the verbal form _flote_; the Teutonic root is _feit_, another form of _feta_, seen in "flow," cf. "feet"); the root is seen in Gr. _πλωτός_ to sail, Lat. _fluere_, to rain; the Lat. _fluo_ and _fluctus_, wave, is not connected, the action of moving on the surface of water, or through the air. The word is used also of a wave, or the flood of the tide, river, barrel of water, or stream, and of any object floating in water, as a mass of ice or weeds; a movable landing-stage, a flat-bottomed boat, or a raft, or, in fishing, of the cork or quill used to support a baited line or fishing-net. It is also applied to the hollow or inflated organ by means of which certain animals, such as the "Portuguese man-of-war," swim, to a hollow metal ball or piece of whinstone, &c., used to regulate the level of water in a tank or boiler, and to a piece of ivory in the eistern of a barometer.

"Float" is also the name of one of the boards of a paddle-wheel or water-wheel. In a theatrical sense, it is used to denote the foofighters attached to a coaus, broad, level and shallow, as a wooden frame attached to a cart or wagon for the purpose of increasing the carrying capacity; and to a special kind of low, broad cart for carrying heavy weights, and to a platform on wheels used for shows in a procession. The term is applied also to various tools, especially to many kinds of trowels used in plastering. It is also used of a dock where vessels may float, as at Bristol, and of the trenches used in "floating" land. In geology and mining, loose rock or ore brought down by water is known as "float," and in tin-mining it is applied to a large trough used for the smelted tin. In weaving the word is used of the passing of weft threads over part of the warp without being woven in with it, also of the threads so passed. In the United States a voter not attached to any particular party and open to bribery is called a "float" or "floater.

FLOCK. 1. (A word found in Old English and Old Norwegian, from which come the Danish and Swedish words, and not in other Teutonic languages), originally a company of people, now mainly, except in figurative usages, of certain animals when gathered together for feeding or moving from place to place. For instance, the flock of goats of his sheep, and generally of sheep and goats. It is from the particular application of the word to sheep that "flock" is used of the Christian Church in its relation to the "Good Shepherd," and also of a congregation of worshippers in its relation to its spiritual head.

2. (Probably from the Lat. _flocus_, but many Teutonic languages have the same word in various forms), a tuft of wool, cotton or similar substance. The name "flock" is given to a material formed of wool or cotton refuse, or of shreds of old woolen or cotton rags, torn by a machine known as a "devil." This material is used for stuffing mattresses or pillows, and also in upholstery. The name is also applied to a special kind of wall-paper, which has an appearance almost like cloth, or, in the more expensive kinds, of velvet. It is made by dusting on a specially prepared adhesive surface finely powdered fibres of cotton or silk. The word "floculent" is used of many substances which have a feecy or "flock"-like appearance, such as a precipitate of ferric hydrate.

FLOOD, or FLOODEN FIELD, near the village of Branxton, in the county of Northumberland, England (10 m. N.W. of Wooler), the scene of a famous battle fought on the 9th of September 1513 between the English and the Scots. On the 22nd of August a great Scottish army under King James IV. had crossed the border. For the moment the earl of Surname (who in King Henry VIII.'s absence was charged with the defence of the realm) had no organized force in the north of England, but James wasted much precious time among the border castles, and when Surname appeared at Wooler, with an army equal in strength to his own, which was now greatly weakened by privations and desertion, he had not advanced beyond Ford Castle. The English commander promptly sent in a challenge to a pitched battle, which the king, in spite of the advice of his most trusted counsellors, accepted. On the 6th of September, however, he led Ford and took up a strong position facing south, on Flooden Edge. Surrey's reproaches for the alleged breach of faith, and a second challenge to fight on Millfield Plain were this time disregarded. The English commander, thus foiled, executed a daring and skilful march round the enemy's flank, and on the 9th drew up for battle in rear of the hostile army. It is evident that Surrey was confident of victory, for he placed his own army, not less than the enemy, in a position where defeat would involve utter ruin. After the disastrous battle fought on Flooden Edge, and the battle fought on Millfield Plain, the Scots, unable quietly to endure their losses, rushed to close quarters. Their left wing drove the English back, but Lord Dacre's reserve corps restored the fight on this side. In all other parts of the field, save where James and Surrey were personally opposed, the English gradually gained ground. The king's corps was then attacked by Surrey in front, and by Sir Edward Stanley in flank. As the Scots were forced back, a part of Dacre's force was thrown out to cut off the Scottish rear, nobly neglecting an almost intact Scottish division in front of him, charged on the rear of King James's corps. Surrounded and attacked on all sides, this, the remnant of the invading army, was doomed. The circle of spearmen around the king grew less and less, and in the end James and a few of his nobles were alone left standing. Soon they too died, fighting to the last man. Among the ten thousand Scottish dead were all the leading men in the kingdom of Scotland, and there was no family of importance that had not lost a member in this great disaster. The "King's Stone," said to mark the spot where James was killed, is at some distance from the actual battlefield.

At Fylde's Well, in Scotland's _Marmion_, is imaginary.

FLODWARD (894-966), French chronicler, was born at Epernay, and educated at Reims in the cathedral school which had been established by Archbishop Fulcon (822-900). As canon of Reims, and favourite of the abbots _Hervaeus_ (d. 922) and _Scullus_ (d. 925), he occupied while still young an important position at the archiepiscopal court, but was twice deprived of his benefices by Heribert, count of Vermandois, on account of his attachment to the other party. On his return he was again appointed bishop of the county of Flatford. The old man had no objection to the election of the count's infant son to the archiepiscopacy. Upon the final triumph of Archbishop _Artold_ in 947, _Floodoard_ became for a time his chief adviser, but withdrew to a monastery in 952, and spent the remaining years of his life in literary and devotional work. His history of the cathedral church at Reims ( _Historia Remensis Ecclesiae_ ) is one of the most remarkable productions of the 10th century. Flobard had been given charge of the episcopal archives, and constructed his history out of the original texts, which he generally reproduces in full; the documents for the period of the current being especially valuable. The _Annales_ which _Floodoard_ wrote year by year from 919 to 966 are doubtfully important, by reason of the author's honesty and the central position of Reims in European affairs in his time. Flobard's poetical works are of hardly less historical interest. The long poem celebrating the triumph of Christ and His saints was called forth by the favour shown him by Pope Leo VII., during whose pontificate he visited Rome, and he devotes fourteen books to the history of the popes.

Flobard's works were published in full by J. P. Migne ( _Patrologia Latina_ , vol. 135); a modern edition of the _Annales_ is published by P. Lauer (Paris, 1896). For bibliography see A. Molièr, _Sources de l'histoire de France_ (No. 593).

FLOE (of uncertain derivation; cf. Norse _flo_, layer, level plain), a sheet of floating ice detached from the main body of polar ice. It is of less extent than the field of "pack" ice, which is a compacted mass of greater depth drifting frequently under the influence of deep currents, while the floating ice is driven by the wind.
FLOOD, H. 525

FLOOD, HENRY (1732–1791), Irish statesman, son of Warden Flood, chief justice of the king's bench in Ireland, was born in 1732, and was educated at Trinity College, Dublin, and afterwards at Christ Church, Oxford, where he became proficient in the classics. His father was a man of good birth and fortune, and he himself married a member of the influential Beresford family, who brought him a large fortune. In his early years he was handsome, witty, good-tempered, and a brilliant conversationalist. His judgment was sound, and he had a natural gift of eloquence which had been cultivated and developed by study of classical oratory and the practice of elocution. Flood therefore possessed every personal advantage when, in 1759, he entered the Irish parliament as member for Kilkenny in his twenty-seventh year. There was at that time no party in the Irish House of Commons that could truly be called national, and until a few years before there had been none that deserved even the name of an opposition. The Irish parliament was still constitutionally subordinate to the English privy council; it had practically no powers of independent legislation, and none of controlling the policy of the executive, which was nominated by the ministers in London (see GRATTAN, HENRY). Though the great majority of the peers were Roman Catholics, no penalty of that faith could either enter parliament or exercise the franchise; the penal code, which made it almost impossible for a Roman Catholic to hold property, to follow a learned profession, or even to educate his children, and which in numerous particulars pressed severely on the Roman Catholics and subjected them to degrading conditions, was as yet unrepealed, though in practice largely obsolete; the industry and commerce of Ireland were throttled by restrictions imposed, in accordance with the economic theories of the period, in the interest of the rival trade of Great Britain. Men like Anthony Malone and Holy-Hutchinson fully realized the necessity for far-reaching reforms, and it only needed the ability and eloquence of Flood in the Irish House of Commons to raise up an independent party in parliament, and to create in the country a public opinion with definite intelligible aims.

The chief objects for which Flood strove were the shortening of the duration of parliament—which had then no legal limit in Ireland except that of the reigning sovereign's life,—the reduction of the scandalously heavy pension list, the establishment of a national militia, and, above all, the complete legislative independence of the Irish parliament. For some years little was accomplished; but in 1768 the English ministry, which had special reasons at the moment for avoiding unpopularity in Ireland, allowed an octennial bill to pass, which was the first step towards making the Irish House of Commons in some measure representative of public opinion. It had become the practice to allow crown patronage in Ireland to be exercised by the owners of parliamentary boroughs in return for their undertaking to manage the House in the government interest. But during the vicereignty of Lord Townsend the aristocracy, and more particularly these "undertakers" as they were called, were made to understand that for the future their privileges in this respect would be curtailed. When, therefore, an opportunity was taken by the government in 1768 for asserting the constitutional subordination of the Irish parliament, these powerful classes were thrown into temporary alliance with Flood. In the following year, in accordance with the established procedure, a money bill was sent over by the privy council in London for acceptance by the Irish House of Commons. Not only was it rejected, but contrary to custom a reason for this course was assigned, namely, that the bill had not originated in the Irish House. In consequence parliament was peremptorily prorogued, and a recess of fourteen months was employed by the government in securing a majority by the most extensive corruption. Nevertheless when parliament met in February 1771 another money bill was thrown out on the motion of Flood; and the next year Lord Townsend, the lord lieutenant whose policy had brought on this conflict, was removed. The following year was the occasion of a publication, famous in its day, called Baratariana, to which

Flood contributed a series of powerful letters after the manner of Junius, one of his collaborators being Henry Grattan.

The success which had thus far attended Flood's efforts had placed him in a position such as no Irish politician had previously attained. He had, as an eminent historian of Ireland observes, "proved himself beyond all comparison the greatest popular orator that his country had yet produced, and also a consummate master of parliamentary tactics. Under parliamentary conditions that were exceedingly unfavourable, and in an atmosphere charged with corruption, venality and subserviency, he had created a party before which ministers had begun to quail, and had inoculated the Protestant constituencies with a genuine spirit of liberty and self-reliance." Lord Harcourt, who succeeded Townsend as viceroy, saw that Flood must be conciliated at any price "rather than risk the opposition of so formidable a leader." Accordingly, in 1775, Flood was offered and accepted a seat in the privy council and the office of vice-treasurer with a salary of £3500 a year. For this step he had been severely criticized. The suggestion that he acted corruptly in the matter is groundless; and although it is true that he lost influence from the moment he became a minister of the crown, Flood would have reason to be satisfied with the development of advancing his policy by the leverage of a ministerial position than by means of any opposition party he could hope to muster in an unreformed House of Commons. The result, however, was that the leadership of the national party passed from Flood to Grattan, who entered the Irish parliament in the same session that Flood became a minister.

Flood continued in office for nearly seven years. During this long period he necessarily remained silent on the subject of the independence of the Irish parliament, and had to be content with advocating minor reforms as occasion offered. He was thus instrumental in obtaining bounties on the export of Irish corn to foreign countries and some other trifling commercial concessions. On the other hand he failed to procure the passing of a Habeas Corpus bill and a bill for making the judges irremovable, while his support of Lord North's American policy still more gravely injured his popularity and reputation. But an important event in 1778 led indirectly to his recovering to some extent his former position in the country; this event was the alliance of France with the revolted American colonies. Ireland was thereby placed in peril of a French invasion, while the English government could provide no troops to defend the island. The celebrated volunteer movement was then set on foot to meet the emergency; in a few weeks more than 40,000 men, disciplined and equipped, were under arms, officered by the country gentry, and controlled by the wisdom and patriotism of Lord Charlemont. This volunteer force, in which Flood was a colonel, while vigilant for the defence of the island, soon made itself felt in politics. A Volunteer Convention, formed with all the regular organization of a representative assembly, but wielding the power of an army, began menacingly to demand the removal of the commercial restrictions which were destroying Irish prosperity. Under this pressure the government gave way; the whole colonial trade was in 1779 thrown open to Ireland for the first time, and other concessions were also extorted. Flood, who had taken an active though not a leading part in this movement, now at last resigned his office to rejoin his old party. He found to his chagrin that his former services had been to a great extent forgotten, and that he was eclipsed by Grattan. When in a debate on the constitutional question in 1779 Flood complained of the small consideration shown him in relation to a subject which he had been the first to agitate, he was reminded that by the civil law "if a man should separate from his wife, and abandon her for seven years, another might then take her and give her his protection." But though Flood had lost control of the movement for independence in the Irish parliament, this agitation, backed as it now was by the Volunteer Convention

2 See Hardy's Life of Charlemont, i. 356.
and by increasing signs of popular disaffection, led at last in 1782 to the concession of the demand, together with a number of other important reforms (see Grattan, Henry).

No sooner, however, was this great success gained than a question arose known as the Simple Repeal controversy—whether to uphold England, in addition to the repeal of the Acts on which the subordination of the Irish parliament had been based, should not be required expressly to renounce for the future all claim to control Irish legislation. The chief historical importance of this dispute is that it led to the memorable rupture of friendship between Flood and Grattan, each of whom assailed the other with unmeasured but magnificently eloquent invective in the House of Commons. Flood's view prevailed—for a Renunciation Act such as he advocated was ungrudgingly passed by the English parliament in 1783—and for a time he gained popularity at the expense of his rival. Flood died (28th of November 1783) before the House had introduced a reform bill, after first submitting it to the Convention Volunteer. The bill, which contained no provision for giving the franchise to Roman Catholics—a proposal which Flood always opposed—was rejected, ostensibly on the ground that the attitude of the volunteers threatened the freedom of parliament. The volunteers were perfectly loyal to the crown and the connexion with England. They carried an address to the king, moved by Flood, expressing the hope that their support of parliamentary reform might be imputed to no other but a sober desire to obtain a just constitution, and to perpetuate the cordial union of both kingdoms." The convention then dissolved, though Flood had desired, in opposition to Grattan, to continue it as a means of putting pressure on parliament for the purpose of obtaining reform.

In 1776 Flood had made an attempt to enter the English House of Commons. In 1783 he tried again, this time with success. He purchased a seat for Winchester from the duke of Chandos, and for the next seven years he was a member at the same time of both the English and Irish parliaments. He reintroduced, but in vain, his reform bill in the Irish House in 1782; he supported the movement for protecting Irish industries; but short-sightedly opposed Pitt's commercial propositions in 1785. He remained a firm opponent of Roman Catholic emancipation, even defending the penal laws on the ground that after the Revolution they "were not laws of persecution but of political necessity"; but after 1786 he does not appear to have attended the parliament in Dublin. In the House at Westminster, where he refused to enrol himself as a member of either political party, he was not successful. His first speech, in opposition to Fox's India Bill on the 3rd of December 1782, was ill received, but in 1787 he carried a reform bill in the Irish House on the question of the Madras Frontier. In 1790 Flood declared to be the best scheme of reform that had yet been proposed, and which in Burke's opinion retrieved Flood's reputation. But at the dissolution in the same year he lost his seat in both parliaments, and he then retired to Farmley, his residence in county Kilkenny, where he died on the 2nd of December 1791.

When Peter Burrowes, notwithstanding his close personal friendship with Grattan, declared that Flood was "perhaps the ablest man Ireland ever produced, indisputably the ablest man of his own times," he expressed what was probably the general opinion of Flood's contemporaries. Lord Charlemont, who knew him intimately though not always in agreement with his policy, pronounced him to be "a man of consummate ability." He also declared that avarice made no part of Flood's character. Lord Mountmorres, a critic by no means partial to Flood, described him as a pre-eminently truthful man, and one who detested flattery. Grattan, who even after the famous quarrel never lost his respect for Flood, said of him that he was the best tempered and the most sensible man in the world. In his youth he was genial, frank, sociable and witty; but in later years disappointment made him gloomy and taciturn. As an orator he was less polished, less epigrammatic than Grattan; but a closer reasoner and a greater master of sarcasm and invective. Personal ambition often governed his actions, but his political judgment was usually sound; and it was the opinion of Bentham that Flood would have succeeded in carrying a reform bill which might have preserved Irish parliamentary independence, if he had been supported by Grattan and the rest of his party in keeping it in the 2nd Convention. Though he never recovered in loyalty to the British crown and empire, Ireland never produced a more sincere patriot than Henry Flood.

FLOOD (in O. Eng. flood, a word common to Teutonic languages, cf. Ger. Flut, Dutch flood, from the same root as is seen in "flow," "float"), an overflow of water, an expanse of water submerging land, a deluge, hence the "flood," specifically, the Noahian deluge of Genesis, but also any other catastrophic submersion recorded in the mythology of other nations than the Hebrew (see Deluge, The). In the sense of "flowing water," the word is applied to the inflow of the tide, as opposed to "ebb."

FLOOD PLAIN, the term in physical geography for a plain of sediment formed by a river. When the slope down which a river runs has become so gentle that the sediment brought from higher regions nearer its source, and consequently the lower portion of the river valley becomes filled with alluvial deposits; and since in times of flood the rush of water in the high regions tears off and carries down a greater quantity of sediment than usual, the river spreads this also over the lower valley where the plain is flooded, because the rush of water is checked, and the stream in consequence drops its extra load. These flood plains are sometimes of great extent. That of the Mississippi below Ohio has a width of from 20 to 80 miles, and its whole extent between its confluence with the Ohio and the mouth of the Ohio, is the result of planation, with aggradation, that is, they may be due to a graded river working in meanders from side to side, widening its valley by this process and covering the widened valley with sediment. Or the stream by cutting into another stream (piracy), by cutting through a barrier near its head waters, by entering a region of looser or softer rock, and by glacial drainage, may form a flood plain simply by filling up its valley (alluviation only). Any obstruction across a river's course, such as a bank of hard rock, may form a flood plain behind it, and indeed anything which checks a river's course and causes the sediment to drop its load will tend to form a flood plain; but it is most commonly found near the mouth of a large river, such as the Rhine, the Nile, or the Mississippi, where there are occasional floods and the river usually carries a large amount of sediment.

"Levees" are formed, inside which the river usually flows, gradually raising its bed above the surrounding plain. Occasional breaches during floods cause the overloaded stream to spread in a great lake over the surrounding country, where the silt covers the ground in consequence. Sections of the Missouri flood plain made by the United States geological survey show the valley bed being scoured at one place, and filled at another by currents and floods of varying swiftness, so that sometimes the deposits are of coarse gravel, sometimes of fine sand, or of fine silt, and it is probable that any section of such an alluvial plain would show deposits of a similar character. The flood plain during its formation is marked by meandering, or anastomosing streams, ox-bow lakes and bayous,
marshes or stagnant pools, and is occasionally completely covered with water. When the drainage system has ceased to act or is entirely diverted owing to any cause, a slow and plain river forms a level area of great fertility, similar in appearance to the floor of an old lake. The flood plain differs, however, inasmuch as it is not altogether flat. It has a gentle slope down-stream, and often for a distance from the sides towards the centre.

**FLOOR** (from O. Eng. floor, a word common to many Teutonic languages, cf. Dutch vloer, and Ger. Flur, a field, in the feminine, and a floor, masculine), generally the lower horizontal surface of a room, but specially employed for one covered with boarding or a carpet. The various levels of rooms in a house are designated as “ground-floor,” “first-floor,” “mezzanine-floor,” etc. The principal floor is the storey which contains the chief apartments whether on the ground- or first-floor; in Italy they are always on the latter and known as the “piano nobile.”

The storey below the ground-floor is called the “basement-floor,” even if only a little below the level of the pavement outside; the storey in a roof is known as the “attic-floor.” The expressions one pair, two pair, etc., apply to the storeys above the first flight of stairs from the ground (see also CARPENTRY).

The rough flannel cloth used for domestic cleaning; also a generic term applied to a variety of materials used in place of carpets for covering floors, and known by such trade names as kamptulicon, oil-cloth, linoleum, corticine, cork-cloth, etc. Kamptulicon (καμπτολίκον, flexible, oδος, thick) was patented in 1844 by E. Galloway, but did not attract much attention till about 1862. It was essentially a preparation of indiarubber masticated up with ground cork, and rolled out into sheets between heavy steam-heated rollers, sometimes over a backing of canvas. Owing to its expensiveness, it has given place to cheaper materials serving the same purpose. Oil-cloth is a coarse canvas which has received a number of coats of thick oil paint, each coat being rubbed smooth with pumice stone before the application of the next. Its surface is ornamented with patterns printed in oil colours by means of wooden blocks. Linoleum (linum, flax, oleum, oil), patented by F. Walton in 1860 and 1863, consists of oxidised linseed oil and ground cork. These ingredients, thoroughly incorporated with the addition of certain gummy and resinous matters, and of pigments such as ochre and oxide of iron as required, are pressed on to a rough canvas backing between steam-heated rollers. Patterns may be printed on its surface with oil paint, or by an improved method may be inlaid with coloured composition so that the colours are continuous through the thickness of the linoleum, instead of being on the surface only, and thus do not disappear with wear. Lincrusta-Walton is a similar material to linoleum, also having oxidised linseed oil as its base, which is stamped out in embossed patterns and used as a covering for walls.

**FLOQUET, CHARLES THOMAS** (1828-1850), French statesman, was born at St Jean-Pied-de-Port (Basses-Pyrénées) on the 2nd of October 1828. He studied law in Paris, and was called to the bar in 1851. The coup d'état of that year aroused the strenuous opposition of Floquet, who had, while yet a student, given proof of his republican sympathies by taking part in the fighting of 1848. He made his name by his brilliant and fearless attacks on the government in a series of political trials, and at the same time contributed to the Temps and other influential journals. When the tsar Alexander II. visited the Palais de Justice in 1867, Floquet was said to have confronted him with the cry, Vive la Pologne, monseigneur! He delivered a scathing indictment of the Empire at the trial of Pierre Bonaparte for killing Victor Noir in 1879, and took part in the revolution of the 4th of September, as well as in the subsequent defence of Paris. In 1871 he was elected to the National Assembly by the department of the Seine. During the Commune he formed the Ligue d'union républicaine des droits de Paris to attempt a reconciliation with the government of Versailles. When his efforts failed, he left Paris, and was imprisoned by order of Thiers, but soon released. He became editor of the République during the Commune, and was chosen president of the municipal council, and in 1876 was elected deputy for the eleventh arrondissement. He took a prominent place among the extreme radicals, and became president of the group of the “Union républicaine.” In 1882 he was raised to the degree of post of the Senate. In 1885 he succeeded M. Briçon as president of the chamber. This difficult position he filled with such tact and impartiality that he was re-elected the two following years. Having approached the Russian ambassador in such a way as to remove the prejudice existing against him in Russia since the incident of 1867, he rendered himself eligible for office; and on the fall of the Tirard cabinet in 1888 he became president of the council and minister of the interior in a radical ministry, which pledged itself to the revision of the constitution, but was forced to combat Reclus, guardian of General Boulangers. Heated debates in the chamber culminated on the 13th of July in a duel between Floquet and Boulangers in which the latter was wounded. In the following February the government fell on the question of revision, and in the new chamber of November Floquet was re-elected to the presidential chair. The Panama scandals, in which he was compelled to admit his implication, dealt a fatal blow to his career: he lost the presidency of the chamber in 1892, and his seat in the house in 1893, but in 1894 was elected to the senate. He died in Paris on the 15th of January 1896.

See Discours et opinions de M. Charles Floquet, edited by Albert Faivre (1885).

**FLOR, ROGER DI**, a military adventurer of the 13th-14th century, was the second son of a falconer in the service of the emperor Frederick II., who fell at Tagliacozzo (1268), and when eight years old was sent to sea in a galley belonging to the Knights Templers. He entered the order and became commander of a galley. At the siege of Acre by the Saracens in 1291 he was accused and denounced to the pope as a thief and an apostate, was degraded from his rank, and fled to Genoa, where he began to play the pirate. The struggle between the kings of Aragon and the French kings of Naples for the possession of Sicily was at this time going on; and Roger entered the service of Frederick, king of Sicily, who gave him the rank of vice-admiral. At the close of the war, in 1302, as Frederick was anxious to free the island from his mercenary troops (called Almagnares), whom he had no longer the means of paying, Roger induced them under his leadership to seek new adventures in the East, in fighting against the Turks, who were ravaging the empire. The emperor Andronicus II. accepted his offer of service; and in September 1303 Roger with his fleet and army arrived at Constantinople. He was adopted into the imperial family, was married to a grand-daughter of the emperor, and was made grand duke and commander-in-chief of the army and the fleet. After some weeks lost in dissipation, intrigues and bloody quarrels, Roger and his men were sent into Asia, and after some successful encounters with the Turks they went into winter quarters at Cacabene. In May 1304 they again took to sea, and rendered the important service of relieving Philadelphia, then invested and reduced to extremities by the Turks. But Roger, bent on advancing his own interests rather than those of the emperor, determined to found in the East a principality for himself. He sent his treasures to Magnesia, but the people slew his Catalans and seized the treasures. He then formed the siege of the town, but his attacks were repulsed, and he was compelled to retire. Being recalled to Europe, he settled his troops in Gallipoli and other towns, and visited Constantinople to demand pay for the Almagnares. Dissatisfied with the small sum granted by the emperor, he plundered the country and carried on intrigues both with and against the emperor, receiving reinforcements all the while from all parts of southern Europe. Roger was now created Caesar, but shortly afterwards the young emperor Michael Palaeologus, not daring to attack the fierce and now augmented bands of adventurers, invited Roger to Adrianople, and there contrived his assassination and the massacre of his Catalan cavalry (April 4, 1306). His death was avenged by his men in a fierce and prolonged war against the Greeks.

See Monceaux, Expedición de los Catalanes y Aragoneses contra Turcos y Griegos (Paris, 1840).
FLORA, in Roman mythology, goddess of spring-time and flowers, later identified with the Greek Chloris. Her festival at Rome, the Flauria, instituted 238 B.C. by order of the Sibyl, took place at the full moon, before summer after 173. It lasted six days (April 28–May 3), the first day being the anniversary of the foundation of her temple. It included theatrical performances and animal hunts in the circus, and vegetables were distributed to the people. The proceedings were characterized by excessive merriment and licentiousness. According to the legend, her worship was instituted by Titus Tatius, and her priest, the flamen Flaurialis, by Numa. In art Flora was represented as a beautiful maiden, bedecked with flowers (Ovid, Fasti, v. 183 ff.; Tacitus, Annals, ii. 49). The term "flora" is used in botany collectively for the plant-growth of a district; similarly "fauna" is used collectively for the animals.

FLORE AND BLANCHEFLEUR, a 13th-century romance. This tale, generally supposed to be of oriental origin, relates the passionate devotion of two children, and their success in overcoming all the obstacles put in the way of their love. The romance appears in differing versions in French, English, German, Swedish, Icelandic, Italian, Spanish, Greek and Hungarian. The various forms of the tale receive a detailed notice in E. Halsall's Die 13. Jahrhundert Middle English poem of "Floris and Blanchefleur" (Samuel, ed. Denkmüller, vol. ii. Berlin, 1885). Nothing definite can be stated of the origin of the story, but France was in the 12th and 13th centuries the chief market of romance, and the French version of the tale, Floire et Blanchefleur, is the most widespread. Floire, the son of a Saracen king of Spain, is brought up in constant companionship with Blanchefleur, the daughter of a Christian slave of noble birth. Floire's parents, hoping to destroy this attachment, send the boy away at fifteen and sell Blanchefleur to foreign slave-merchants. When Floire returns to her in a few days later she is told that his companion is dead, but when he threatens to kill himself, his parents tell him the truth. He traces her to the tower of the maidens destined for the harem of the emir of Babylon, into which he penetrates concealed in a basket of flowers. The lovers are discovered, but their constancy touches the hearts of their judges. They are married, and Floire returns to his kingdom, when he and all his people adopt Christianity.

Of the two 12th-century French poems (ed. Éléonore du Merlet, Paris, 1850), the one contains the love story with few additions, the other is a romance of chivalry containing the usual battles, single combats, &c. The Floire based on episodes of the story are published by Paulin Paris in his Romançoir françois (Paris, 1883). The English poem renders the French version without amplifications, such as are found in other adaptations. Its author has less sentiment than his original, and less taste for detailed description. Among the other forms of the story must be noted the prose romance (c. 1340) of Boccaccio, Il Filoaco, and the 14th-century Legenda regina Rosam et di Rosame sua fighiula (pr. Leghorn, 1871). The similarity between the story of Floire and Blanchefleur and Chante-fable of Aucausin et Niolette 1 has been repeatedly pointed out, and they have been even credited with a common source.

See also editions by J. Bekker (Berlin, 1844) and E. Hausknecht (Berlin, 1885); also H. Sundmacher, Die altfr. und mittelhochdeutsche Bearbeitung der Saga von Floire et Blanchefleur (Göttingen, 1872); H. Herzog, Die beiden Sagenkreise von Floire und Blanchefleur (Vienna, 1884); Zeitschrift für deut. Altertum (vol. xxiii.) contains a French version; the Scandinavian Flores Saga ok Blanchfjær, ed. E. Kölbing (Halle, 1906); the 13th-century versions of Vital Flecker, Flori et Blanchefleure, ed. E. Sommer (Leipzig, 1856); the Swedish by G. E. Klemming (Stockholm, 1844). The English poem was also edited by H. Forester (English Metrical Tales, 1829), by L. Abbott (Abbotsford Club, 1829), and by Lumby (Early Eng. Text Soc., 1866); G. H. McKnight, 1901); R. Reinhold (Floire et Blanchefleur, Paris, 1906) shows a parallelism with the story of Cupid and Psyche as told by Apuleius; also that the oriental setting does not necessarily imply a connexion with Arab tales, as the critical manuscript tradition with few small alteration have been taken from the Vulgate version of the book of Esther.

FLORENCE, WILLIAM JERMYN (1834–1901), American actor, of Irish descent, whose real name was Bernard Conlin, was born on the 26th of July 1831 at Albany, N.Y., and first appeared at the attention of Hugh B. Lyceum in 1857. Two years later he married Mrs Malvina Pray Littell (d. 1906), in association with whom, until her retirement in 1889, he won all his successes, notably in Benjamin Woolf's The Mighty Dollar, said to have been presented more than 2500 times. In 1856 they had a successful London season, Mrs Florence being one of the first American actresses to appear on the English stage. FLORENCE entered into partnership with Joseph Jefferson, playing Sir Lucius O'Trigger to his Bob Acres and Mrs John Drew's Mrs Malaprop on a very successful tour. His last appearance was with Jefferson on the 14th of November 1861, as Ezekiel Homespun in The Heir-at-law, and he died on the 18th of November in Philadelphia.

FLORENCE OF WORCESTER (d. 1115), English chronicler, was a monk of Worcester, who died, as we learn from his continuator, on the 7th of July 1115. Beyond this fact nothing is known of his life. He compiled a chronicle called Chronicon ex chronicis which begins with the creation and ends in 1117. The basis of his work was a chronicle compiled by Mariani Scota, an Irish recluse, who lived first at Fulda, afterwards at Mairianus, whom he began his work after 1069, carried it up to 1082. Florence supplemented Mariani's Chronicle of the English Chronicle, and from Asser. He is always worth comparing with the extant English Chronicles; and from 1106 he is an independent annalist, dry but accurate. Either Florence or a later editor of his work made considerable borrowings from the first four books of Eadmer's Historia novorum. Florence's work is continued, up to 1141 by a certain John of Worcester, who wrote about 1150. John is valuable for the latter years of Henry I. and the early years of Stephen. He is friendly to Stephen, but not an indiscriminate partisan.

The first edition of these two writers is that of 1592 (by William Howard). The most accessible is that of B. Thorpe (Eng. Hist. Soc., 2 vols., 1848–1849); but Thorpe's text of John's continuation needs revision. Thorpe gives, without explanations, the insertions of an ill-informed Gloucester monk who has obscured the accurate chronology of the original. Thorpe also prints a continuation by John Tucker (died c. 1295), a 13th-century writer and a monk of Bury St Edmunds. Florence and John of Worcester are translated by J. Stow, in his Church Historian of England, 1722; and by John Conlin (1853); T. Forester's translation in Bohn's Antiquarian Library (London, 1854) gives the work of Tucker also. (H. W. C. D.)

FLORENCE, the county-seat of Lauderdale county, Alabama, U.S.A., on the N. bank of the Tennessee river, at the foot of Muscle Shoals Canal, and about 560 ft. above sea-level. Pop. (1880) 1359; (1890) 6012; (1900) 6478 (1952 negroes); (1910) 6685. It is served by the Southern, the Northern Alabama (controlled by the Southern), and the Louisville & Nashville railways, and by electric railway to Sheffield and Tuscumbia, and the Tennessee river is here navigable. Florence is situated in the fertile agricultural lands of the Tennessee river valley on the edge of the coal and iron districts of Alabama, and has various manufactures, including pig-iron, cotton goods, wagons, stoves, fertilizers, staves and mercantile supplies. At Florence are the state Normal College, the Florence University for Women, and the Burrell Normal School (for negroes; founded in 1903 by the American Missionary Association). Florence was founded in 1818, Andrew Jackson, afterwards president of the United States, having been one of the early residents among the early property holders. For several years Florence and Nashville, Tennessee, were commercial rivals, being situated respectively at the head of navigation on the Tennessee and Cumberland rivers. The first invasion of Alabama by Federal troops in the Civil War was by a gunboat raid up the Tennessee to Florence on the 8th of February 1862. On the 11th of April 1863 another Federal gunboat raid was attempted, but the vessels were repulsed by a force under Gen. S. A. Wood. On the 26th

1 Ed. H. Suchier (Paderborn, 1878, 5th ed. 1901); modern French by G. Michaut, with preface by J. Bédier (Tours, 1901); English by Andrew Lang (1887), by F. W. Bourdillon (Oxford, 1896), and by Laurence Housman (1902).
of May following, Federal troops entered Florence, and destroyed cotton mills and public and private property; but they were driven back by Gen. Philip D. Roddy (1830–1857) on the 11th of December 1863 the town was again raided, but the Federals did not secure permanent possession. Florence was chartered as a city in 1889.

**Florence (Ital. Firenze, Lat. Florentia), formerly the capital of Tuscany, now the capital of a province of the kingdom of Italy, and the sixth largest city in the country. It is situated 43° 40' N., 11° 12' E., on both banks of the river Arno, which at this point flows through a broad fertile valley enclosed between spurs of the Apennines. The city lies 25 ft. above sea-level, and occupies an area of 3 sq. m. (area of the commune, 165 sq. m.). The geological formation of the soil belongs to the Quaternary and Pliocene period in its upper strata, and to the Eocene and Cretaceous in the lower. **Pietra forte** of the Cretaceous period is quarried north and south of the city, and has been used for centuries as paving stone and for the buildings. **Pietra serena** or *macigno*, a stone of a firm texture also used for building purposes, is quarried at Monte Ceceri below Fiesole. The soil is very fertile; wheat, Indian corn, olives, vines, fruit trees of many kinds grow on the plain and the surrounding hills; the chief non-fruit-bearing trees are the stone pine, the cypress, the ilex and the poplar, while many other varieties are represented. The gardens and fields produce an abundance of flowers, which justify the city's title of *la città dei fiori*.  

**Climate and Sanitary Conditions.**—The climate of Florence is very variable, ranging from severe cold accompanied by high winds from the north in winter to great heat in the summer, while in spring-time sudden and rapid changes of temperature are frequent. At the same time the climate is usually very agreeable from the end of February to the beginning of July, and from the end of September to the middle of November. The average temperature throughout the year is about 50° Fahr.; the maximum heat is about 96°–98°, and the minimum 36°–38°, sometimes sinking to 21°. The longest day is 15 hours and 33 minutes, the shortest 8 hours and 50 minutes. The average rainfall is about 37 inches. Epidemic diseases are rare and children's diseases mild; cholera has visited Florence several times, but the city has been free from it for many years. Diphtheria first appeared in 1868 and continued as a severe epidemic until 1872, since when it has only occurred at rare intervals and in isolated cases. Typhoid, pneumonia, tuberculosis, measles and scarlatina, and influenza are the commonest illnesses. The drainage system is still somewhat imperfect, but the water brought from the hills or from the Arno in pipes is fairly good, and the general sanitary conditions are satisfactory.

**Public Buildings.**—Of the very numerous Florentine churches the Duomo (Santa Maria del Fiore) is the largest and most important, founded in 1298 on the site of the church of Arnolfo di Cambio, completed by Brunelleschi, and consecrated in 1436; the façade, however, was not finished until the 14th century—it was begun in 1275 on the designs of de Fabris and unveiled in 1888. Close by the Duomo is the no less famous Campanile built by Giotto, begun in 1332, and adorned with exquisite bas-reliefs. Opposite is the Baptistery built by Arnolfo di Cambio in the 13th century on the site of an earlier church, and adorned with beautiful bronze doors by Ghiberti in the 15th century. The Badia, Santo Spirito, Santa Maria Novella, are a few among the many famous and beautiful churches of Florence. The existence of these works of art attracts students from all countries, and a German art school subsidized by the imperial government has been instituted.

The streets and piazze of the city are celebrated for their splendid palaces, formerly, and in many cases even to-day the residences of the noble families of Florence. Among others we may mention the Palazzo Vecchio, formerly the seat of the government of the Republic and now the town hall, the Palazzo Riccardi, the residence of the Medici and the present seat of government; the Palazzo Medici (one of the most perfect specimens of Florentine quattrocento architecture), Corsini, Davanzati, Pitti (the royal palace), &c. The palace of the Arte della Lana or
gild of wool merchants, tastefully and intelligently restored, is the headquarters of the Dante Society. The centre of Florence, let alone becoming a danger from a hygienic point of view, was pulled down in 1880–1881 but, unfortunately, sufficient care was not taken to destroy certain buildings of historic and artistic value which might have been spared without impairing the work of sanitation, while the new structures erected in their place, especially those in the Piazza Vittorio Emanuele, are almost uniformly ugly and quite out of keeping with Florentine architecture. The question aroused many polemics at the time both in Italy and abroad. After the new centre was built, a society called the Società per la difesa di Firenze antica was formed by many citizens to safeguard the ancient buildings and prevent them from destruction, and a spirit of intelligent conservatism seems now to prevail in this connexion. The city is growing in all directions, and a number of new quarters have sprung up where the houses are more sanitary than in the older parts, but unfortunately few of them evince much aesthetic feeling. The viali or boulevards form pleasant residential streets with gardens, and the system of building separate houses for each family (villini) instead of large blocks of flats is becoming more and more general.

Florence possesses four important libraries besides a number of smaller collections. The *Biblioteca Nazionale*, originally founded by Antonio Magliabecchi in 1747, enjoys the right, shared by the Vittorio Emanuele library of Rome, of receiving a copy of every work printed in Italy, since 1870 (since 1843 it had enjoyed a similar privilege with regard to works printed in Tuscany). It contains some 500,000 printed volumes, 700,000 pamphlets, over 9000 prints and drawings (including 284 by Albert Dürer), nearly 20,000 MSS., and 40,000 books. The number of readers in 1904 was over 50,000. Unfortunately, however, the confusion engendered by a defective organization has long been a byword among the people; there is no printed catalogue, quantities of books are buried in packing-cases and unavailable, the collection of foreign books is very poor, hardly any new works being purchased, and the building itself is quite inadequate and far from safe; but the site of a new one has now been purchased and the plans are agreed upon, so that eventually the whole collection will be transferred to more suitable quarters. The *Biblioteca Marucelliana*, founded in 1752, contains 150,000 books, including 620 incunabula, 17,000 engravings and 1500 MSS.; it is well managed and chiefly remarkable for its collection of illustrated works and art publications. The *Biblioteca Mediceo-Laurenziana*, founded in 1571, has its origin in the library of Cosimo de' Medici the Elder, and was enlarged by Piero, Giovanni and above all by Lorenzo the Magnificent. Various princes and private persons presented it with valuable gifts and legacies, among the most important of which was the collection of *luce principis* given by Count D'Albertis in 1841, and the Ashburnham collection of MSS. purchased by the Italian Government in 1885. It contains nearly 10,000 MSS., including many magnificent illuminated missals and Bibles and a number of valuable Greek and Latin texts, 242 incunabula and 11,000 printed books, chiefly dealing with palaeography; it is in some ways the most important of the Florentine libraries. The *Biblioteca Riccardiana*, founded in the 17th century by Romolo Riccardi, contains nearly 4000 MSS., over 57,000 books and 650 incunabula, chiefly relating to Florentine history. The state archives are among the most complete in Italy, and contain over 450,000 *file* and *registri* and 126,000 charters, covering the period from 726 to 1836.

Few cities are as rich as Florence in collections of works of artistic and historic interest, although the great majority of them belong to a comparatively limited period—from the 15th to the 16th century. The chief art galleries are the Uffizi, the Pitti and Accademia. The two last are among the most famous in the world, but, unfortunately, insufficient care is taken in the latter to prevent it being filled with masterpieces by Raphael, Andrea del Sarto, Perugino, Ghirlandajo, Botticelli, the Lippi, and many other Florentine, Umbrian, Venetian, Dutch and Flemish artists, as well as numerous admirable examples of antique, medieval and Renaissance

*Libraries.*

*Galleries of Fine Art and Museums.*
Florence was founded considerably later than Faesulae (Fiesole), which lies on the hill above it; indeed, as its name indicates, it was built only in Roman times and probably in connexion with the construction by C. Flaminius in 187 B.C. of a road from Bononia to Arretium (which later on formed part of the Via Cassia) at the point where this road crossed the river Arno. We hear very little of it in ancient times; it appears to have suffered at the end of the war between Marcus Aurelius and Sulla and in A.D. 15 (by which period it seems to have been already a colony) it successfully opposed the project of diverting part of the waters of the Clāns into the Arno (see Chiana). Tacitus mentions it, and Florus describes it as one of the municipia splendidissima. A bishop of Florence is mentioned in A.D. 313. A group of Italian cremation tombs a pozzo of the Villanov period were found under the pavement of the medieval Vicolo del Campidoglio. This took its name from the Capitolium of Roman times, the remains of which were found under the Piazza della Luna; the three collae were clearly traceable. The capitals of the columns were Corinthian, about 4 ft. in diameter, and it became clear that this temple had supplied building materials for S. Giovanni and S. Miniato. Fragments of a fine octagonal altar, probably belonging to the temple, were found. Remains of baths have been found close by, while the ancient amphitheatre has been found near S. Croce outside the Roman town, which formed a rectangle of about 400 by 600 yds., with four gates, the Decumanus being represented by the Via Strozzi and the Cardinale, and the Via Calimala, while the Mercato Vecchio occupied the site of the Forum.

See L. Milani, "Reliquie di Firenze antica," in Monumenti dei Lincei, vi. (1896), 5 seq.

(T. As.)

The first event of importance recorded is the siege of the city by the Goths, A.D. 425, and its deliverance by the Roman general Stilicho. Totila besieged Florence in 542, but was repulsed by the imperial garrison under Justin, and later it was occupied by the Goths. We find the Longobards in Tuscany in 570, and mention is made of one Godibrando Ducx civitatis Florentinorum, who suggests that at that time Florence was the capital of a duchy (one of the regular divisions of the Longobard empire). Charles I of Sweden was in Florence in 1786 and conferred many favours on the city, which continued to grow in importance owing to its situation on the road from northern Italy to Rome. At the time of the agitation against simony and the corruption of the clergy, the head of the movement in Florence was San Giovanni Gualberto, of the monastery of San Salvi. The simoniacal election of Pietro Mezzabarba as bishop of Florence (1066) caused serious disturbances and a long controversy with Rome, which ended in the triumph of the candidate, of the monk Pietro I igneus, champion of the popular reform movement; this event indicates the beginnings of a popular conscience among the Florentines.
Under the Carolingian emperors Tuscany was a March or margraviate, and the marquises became so powerful as to be even a danger to the Empire. Under the emperor Otto I. one Ugo (d. 1001) was marquis, and the emperor Conrad II. (elected in 1024) appointed Boniface of Canossa marquis of Tuscany, a territory then extending from the Po to the borders of the Roman state. Boniface died in 1052, and in the following year the margraviate passed to his daughter, the famous countess Matilda, who ruled for forty years and played a prominent part in the history of Italy in the time of the hini homines. In the Wars of the Investitures Matilda was ever on the papal (afterwards called Guelph) side against the emperor and the faction afterwards known as Ghibelline, and she herself often led armies to battle. It is at this time that the people of Florence first began to acquire influence, and while the countess presided at the courts of justice in the name of the Empire, she was assisted by a group of great feudal nobles, judges, lawyers, &c., who, formed, as elsewhere in Tuscany, the boni homines or sapiences. As the countess was frequently absent these boni homines gave judgment without her, thus paving the way for a free commune. The citizens found themselves in opposition to the nobility of the hills around the city, Teutonic feudatories of Ghibelline sympathies, who interfered with their commerce. Florence frequently waged war with these nobles and with other cities on its own account, although in the name of the countess, and the citizens began to form themselves into groups and associations which were the germs of the arri or gilds. After the death of Countess Matilda in 1136 the grand or boni homines continued to rule and administer justice, but in the name of the people—a change hardly noticed at first, but which marks the foundation of the commune.

After 1138 the boni homines began to be called consules, while the population was divided into the grandi or dette tori, i.e. the noble families who had towers, and the arri or trade and merchant gilds. At first the consules, of whom there seem to have been twelve, two for each sestiere or ward, were chosen by the men of the towers, and assisted by a council of 100 boni homines, in which the arri were predominant; the government thus came to be in the hands of a few powerful families. The republic now proceeded to extend its power. In 1135 Fiesole was sacked and destroyed, but the feudal nobles of the contado (surrounding country), protected by the imperial margraves, were still powerful. The early margraves had permitted the Florentines to wage war against the Alberti family, whose castles they destroyed. The emperor Lothair when in Italy forced Florence to submit to his authority, but at his death in 1137 things returned to their former state and the Florentines fought successfully against the powerful Frederick II, who, according to Tuscany, however, elected emperor in 1152, made his authority felt in Tuscany, and appointed one Welf of Bavaria as margrave. Florence and other cities were forced to supply troops to the emperor for his Lombard campaigns, and he began to establish a centralized imperial bureaucracy in Tuscany, appointing a podestà, who resided at San Miniato (whence the name of “San Miniato al Tedesco”), to represent him and exercise authority in the contado; this double authority of the consoli in the town and the podestà of podestà outside generated confusion. In 1176 the Florentines were masters of all the territory comprised in the dioceses of Florence and Fiesole; but civil commotion within the city broke out between the consoli and the greater nobles, headed by the Alberti and strengthened by the many feudal families who had been forced to leave their castles and dwell in the city (1177-1180). In the end the Alberti, though not victorious, succeeded in getting occasionally admitted to the consulship. Florence now formed a league with the chief cities of Tuscany, made peace with the Guidi, and extended its power to all the territory of Seminforte and Verrucchio (1129). Later we find a podestà within the city, elected for a year and assisted by seven councillors and seven rectores super capitibus urbis. This represented the triumph of the feudal party, which had gained the support of the arri minori or minor gilds. The podestàs subsequently were foreigners, and in 1207 the dignity was conferred on Guidfredotto of Milan; a new council was formed, the consiglio del comune, while the older senate still survived. The Florentines now undertook to open the highways of commerce towards Rome, for their city was already an important industrial and banking centre.

Discord among the great families broke out again, and the attempt to put an end to it by a marriage between Buonelmonte degli Alidinesi and a daughter of the Amidei, only led to further strife (1215), although the causes of these broils were deeper and wider, being derived from the general division between Guelphs and Ghibellines all over Italy. But the work of crushing the nobles of the contado and of asserting the city's position among rival communes continued. In 1222 Florence waged war successfully on Pisa, Lucca and Pistoia, and during the next few years against the Siensese with varying results; although the emperor supported the latter as Ghibellines, on his departure for Germany in 1225 they were forced to accept peace on onerous terms. During the interregnum (1244-1245) following on the death of Pope Gregory IX. the Ghibelline cause revived in Tuscany and imperial authority was re-established. The tumults against the Paterine heretics (1244-1245), among whom were many Ghibelline nobles favoured by the podestà Pace di Pesamiagola, indicate a successful Guelphic reaction; but Frederick II., having defeated his enemies both in Lombardy and in the Two Sicilies, appointed his natural son, Frederick of Antioch, imperial vicar in Tuscany, who, when civil war broke out, entered the city with 300 German knights. The Ghibellines now triumphed completely, and in 1249 the Guelph leaders were driven into exile—the first of many instances in Florentine history of exile en masse of a defeated party. The attempt to seize Montevarchi and other castles where the Guelph exiles were congregated failed, and in 1250 the burgheers elected thirty-six caporali di popolo, who formed the basis of the primo popolo or body of citizens independent of the nobles, headed by the capitano del popolo. The Ghibellines being unable to maintain their supremacy, the city came to be divided into two almost autonomous republics, the commune headed by the podestà, and the popolo headed by the capitano and militarily organized into twenty companies; the central power was represented by twelve amianzi or elders. The podestà, who was always a foreigner, usually commanded the army, represented the city before foreign powers, and signed treaties. He was assisted by the consiglio speciale of 90 and the consiglio generale e speciale of 300, composed of nobles, while the capitano del popolo had also two councils composed of burgheers, heads of families, and foreigner, who, with the capitaneo del popolo, was a council of 36 burgheers, and then there was the parlamento or general assembly of the people, which met only on great occasions. At this time the podestà's palace (the Bargello) was built, and the gold florin was first coined and soon came to be accepted as the standard gold piece throughout Europe. But, although greatly strengthened, the Guelphs, who now may be called the democrats as opposed to the Ghibelline aristocrats, were by no means wholly victorious, and in 1251 they had to defend themselves against a league of Ghibelline cities (Siena, Pisa and Pistoia) assisted by Florentine Ghibellines; the Florentine Uberti, who had been driven into exile after their plot of 1258, took refuge in Siena and encouraged that city in its hostility to Florence. Fresh disputes about the possession of Montepulciano and other places having arisen, the Florentines declared war once more. A Florentine army assisted by Guelphs of other towns was cunningly induced to believe that Siena would surrender at the first summons; but it was met by a Siensese army reinforced by Florentine exiles, including Pisan and Sienese troops, and the war continued till the death of Manfred (g.v.) of Sicily, led by Count Giordano and the count of Arras, with the result that the Florentines were totally routed at Montaperti on the 4th of September 1260. Count Giordano entered Florence, appointed Count Guido Novello podestà, and began a series of persecutions.
FLORENCE

against the Ghibellines. The Ghibellines even proposed to raze the walls of the city, but Farinata degli Uberti strongly opposed the idea, saying that "he had fought to regain and not to ruin his fatherland."

During this new Ghibelline predominance (1260-1266) the old liberties were abolished, and the popolo was deprived of all share in the administration. But when Charles I. (q.v.) of Anjou descended into Italy as champion of the papacy, and Manfred was defeated and killed (1266), the popolo, who had acquired wealth in trade and industry, was ready to rise. After some disturbances Guido Novello and the Ghibellines were expelled, but it was not the popolo who triumphed; the pope and Charles were the real masters of the situation, and the Florentines found they had exchanged a foreign and Ghibelline protector for one who was foreign and Guelph. Nevertheless much of the old order was restored; the podestà who represented King Charles was assisted by 12 buoni uomini, and by the council of the 100 buoni uomini del popolo, "without the deliberation of whom," says Villani, "no great matter nor expenditure could be undertaken." Other bodies and magistrates were maintained, and the capitano del popolo, now called capitano della massa di parte Guelfa, tended to become a very important person. The property of the Ghibellines was confiscated, and a commission of six capitani di parte Guelfa appointed to administer it and in general to expend it for the persecution of the Ghibellines. The whole constitution of the republic, although of very democratic tendencies, seemed designed to promote civil strife and weaken the central power.

While the constitution was evolving in a manner which seemed to argue small political ability and stability in the Florentines, the people had built up a wonderful commercial organization. Each of the seven arti maggiori or greater gilds was organized like a small state with its councils, statutes, assemblies, magistrates, &c., and in times of trouble constituted a citizen militia. Florentine cloth especially was known and sold all over Europe, and the Florentines were regarded as the first merchants of the age. If the life of the city went on uninterrupted even during the many changes of government and the almost endemic civil war, it was owing to the solidity of the gilds, who could carry on the administration without the help of the clergy.

After Charles's victory over Conradin in 1268 the Florentines defeated the Sienese (1269) and made frequent raids into Pisan territory. As Charles perpetually interfered in their affairs, always favouring the grandi or Guelph nobles, some of the Ghibellines were recalled as a counterpoise, which, however, only led to further civil strife. Rudolph of Habsburg, elected king of the Romans in 1273, having come to terms with Pope Nicholas III., Charles was obliged in 1278 to give up his title of imperial vicar in Tuscany, which he had held during the interregnum following on the death of Frederick II. In 1279 Pope Nicholas sent his nephew, the friar preacher Latino Frangipani Malabranca, whom he had created cardinal bishop of Ostia the same year, to reconcile the parties in Florence once more. Cardinal Latino to some extent succeeded, and was granted a kind of temporary dictatorship. He raised the 12 buoni uomini to 14 (8 Guelphs and 6 Ghibellines), to be changed every two months; and they were assisted by a council of 100. A force of 1000 men was placed at the disposal of the podestà and capitano (now both elected by the people) to keep order and oblige the grandi to respect the law. The Sicilian Vespers (q.v.) by weakening Charles strengthened the commune, which aimed at complete independence of emperors, kings and popes. After 1282 the signoria was composed of the 3 (afterwards 6) priori of the gilds, who ended by ousting the buoni uomini, while a defensor artificem et arrium takes the place of the capitano; thus the republic became an essentially trading community, governed by the popolani grassi or rich merchants.

The republic now turned to the task of breaking the power of the Ghibelline cities of Pisa and Arezzo. In 1289, the Arretini were completely defeated by the Florentines at Campaldino, a battle made famous by the fact that Dante took part in it. War against the Pisans, who had been defeated by the Genoese in the naval battle of La Meloria in 1284, was carried on in a desultory fashion, and in 1293 peace was made. But the grandi, who had largely contributed to the victory of Campaldino, especially men like Corso Donati and Vieri de' Cerchi, were becoming more powerful, and Charles had increased their number by creating a great many knights; but their attempts to interfere with the administration of justice were severely repressed, and new laws were passed to resist the influence of the grandi. Many other internal reforms the abolition of the last traces of servitude in 1284, and the increase in the number of arti, from 12 to 21 (7 maggiori and 14 minori) must be mentioned. This, however, was not enough for the Florentine democracy, who viewed with alarm the increasing power and arrogance of the grandi, who in spite of their exclusion from many offices were still influential and constituted independent clans within the state. The law obliged each member of the clan (consoritaria) to sodare for all the other members, i.e. to give a pecuniary guarantee to ensure payment of fines for offences committed by any one of their number, a provision made necessary by the fact that the whole clan acted collectively.

But as the laws were not always enforced new and severe ones were enacted. These were the famous Ordinamenti Ordinari della Giustizia of 1293, by which all who were not of the arti were definitely excluded from the signory. Giustizia (1293).

The priori were to remain in office two months and a day, elected the gonfaloniere, also for two months; there were the capitidumi or councils of the gilds, and two savi for each sestiere, with 1000 soldiers at their disposal; the number of the grandi families was fixed at 38 (later 72). Judgment in matters concerning the Ordinamenti was delivered in a summary fashion without appeal. The leading spirit of this reform was Giano della Bella, a noble who by engaging in trade had become a popolano; the grandi now tried to make him unpopular with the popolani grassi, hoping that without him the Ordinamenti would not be executed, and opened negotiations with Pope Boniface VIII. (elected 1294), who aimed at extending his authority in Tuscany. A signory adverse to Giano having been elected, he was driven into exile in 1295. The grandi regained some of their power by corrupting the podestà and by the favour of the popolo minuto or unorganized populace; but their quarrels among themselves prevented them from completely succeeding, while the arti were solid.

In 1295 a signory favourable to the grandi enacted a law attenuating the Ordinamenti, but now the grandi split into two factions, one headed by the Donati, which hoped to abolish the Ordinamenti, and another by the Cerchi, which had given up all hope of their abolition; afterwards these parties came to be called Neri (Blacks) and Bianchi (Whites). A plot of the Donati to establish their influence over Florence with the help of Boniface VIII. having been discovered (May 1300), serious riots broke out between the Neri and the Bianchi. The pope's attempt to unite the grandi having failed, he summoned Charles of Valois to come to his assistance, promising him the imperial crown; in 1301 Charles entered Italy, and was created by the pope pacifico or peacemaker of Tuscany, with instructions to crush the Bianchi and the popolo and exalt the Neri. On the 1st of November Charles reached Florence, promising to respect its laws: but he permitted Corso Donati and his friends to attack the Bianchi, and the new podestà, Cante dei Gabrielli di Gubbio, who had come with Charles, punished many of that faction; among those whom he exiled was the poet Dante (1302). Corso Donati, who for some time was the most powerful man in Florence, made himself many enemies by his arrogance, and was obliged to rely on the popolo grasso, the irritation against him resulting in a rising in which he was killed (1308). In this same year Henry of Luxemburg was elected king of the Romans and with the pope's favour he came to Italy in 1310; the Florentine exiles and all the Ghibellines of Italy regarded him as a saviour and regenerator of the country, while the Guelphs of Florence on the contrary opposed
both him and the pope as dangerous to their own liberties and accepted the protection of King Robert of Naples, disregarding Henry's summons to submission. In 1322 Henry was crowned emperor as Henry VII in Rome, but instead of the universal ruler and pacifier which he tried to be, he was forced by circumstances into being merely a German kaiser who tried to subjugate free Italian communities. He besieged Florence without success, and died of disease in 1313.

The Pisans, fearing the vengeance of the Guelphs now that Henry was dead, had accepted the lordship of Ugucione della Faggionola, imperial vicar in Genoa. A brave general and an ambitious man, he captured Lucca and defeated Florence and Tuscany. In 1325 he laid siege to Pisa, and the following year he lost both Lucca and Pisa and had to fly from Tuscany. A new danger now threatened Florence in the person of Castruccio Castracani degli Antelminelli (q.v.), who made himself lord of Lucca and secured help from Matteo Visconti, lord of Milan, and other Ghibellines of northern Italy. Between 1320 and 1323 he harried the Florentines and defeated them several times, captured Pistoia, devastated their territory up to the walls of the city in spite of assistance from Naples under Raymundo de la Nave, and the Pisans, and the Maremma inhabitants. Never before had Florence been so humiliated, but while Castruccio was preparing to attack Florence he died in 1328.

Two months later the duke of Calabria, who had been appointed protector of the city in 1325, died, and further constitutional reforms were made. The former councilors were replaced by the consiglio del popolo, consisting of 300 popolani and presided over by the capitano, and the consiglio del comune of 250 members, half of them nobles and half popolani, presided over by the podestà. The priori and other officers were drawn by lot from among the Guelphs over thirty years old who were destined for public office by a special board of 98 citizens (1329). The system worked well at first, but abuses soon crept in, and many persons were unjustly excluded from office; trouble being expected in 1335 a captain of the guard was created. But the first one appointed, Jacopo dei Gabrielli di Gubbio, used his dictatorial powers so ruthlessly that at the end of his year of office no successor was chosen.

The Florentines now turned their eyes towards Lucca; they might have acquired the city immediately after Castruccio's death if for 80,000 florins, but failed to do so owing to the differences of opinion in the signory; Martino della Scala, lord of Verona, promised it to them in 1335, but broke his word, and although their finances were not then very flourishing they allied themselves with Venice to make war on him. They were successful at first, but Venice made a truce with the Scala independently of the Florentines, and by the peace of 1339 they only obtained a part of Lucchese territory. At the same time they purchased from the Tarlati the protectorate over Arezzo for ten years. But misfortunes fell on the city; Edward III. of England repudiated the heavy debts contracted for his wars in France with the Florentine banking houses of Bardi and Peruzzi (1339), which eventually led to their failure and to that of many smaller firms, and shook Florentine credit all over the world; Philip VI. of France extorted large sums from the Florentine merchants and bankers in his dominions by accusing them of usury; in 1340 plague and famine wrought terrible havoc in Florence, and riots again broke out between the grandi and the popolo, partly on account of the late unsuccessful wars and the unsatisfactory state of the finances. To put an end to these disorders, Walter of Brienne, duke of Athens, was elected "conservator" and captain of the guard in 1342. An astute, deliberate and ambitious man, half French and half Levantine, he began his government by a policy of conciliation and impartial justice which won him great popularity. But as soon as he thought the ground was secure he succeeded in getting himself acclaimed by the populace lord of Florence for life, and on the 8th of September was carried in triumph to the Palazzo della Signoria. The podestà and the capitano asseenting to this treachery, he dismissed the gonfaloniere, reduced the priori to a position of impotence, disarmed the citizens, and soon afterwards accepted the lordship of Arezzo, Volterra, Colle, San Gimignano and Pistoia. He increased the body of men an Florence, who behaved with the greatest licence and brutality; by his oppressive taxes, and his ferocious cruelty towards all who opposed him, and the unsatisfactory treaties he concluded with Pisa, he accumulated bitter hatred against his rule. The grandi were disappointed because he had not crushed the popolo, and the latter because he had destroyed their liberties and interfered with the organization of the arti. Many unsuccessful plots against him were hatched, and having discovered one that he conducted by Antonio degli Adimari, the duke summoned the latter to the palace and detained him there. He also summoned 300 leading citizens on the pretext of wishing to consult them, but fearing treachery they refused to come. On the 26th of July 1343, the citizens rose in arms, demanded the duke's abdication, and besieged him in the palace. Help came to the Florentines from neighbouring cities, the podestà was expelled, and a bolla or provisional government of 14 was elected. The duke was forced to set Adimari and his other prisoners free, and several of his men-at-arms were killed by the populace; the money he had invested in the house had given him 200,000 florins, which were literally torn to pieces, and finally on the 1st of August he had to resign his lordship. He departed from Florence under a strong guard a few days later, and the Fourteen cancelled all his encomiums.

The expulsion of the duke of Athens was followed by several measures to humble the grandi still further, while the podestà minuto or artisans began to show signs of discontent at the rule of the merchants, and the populace destroyed the houses of many nobles. As soon as order was restored a bolla was appointed to reform the government, in which task it was assisted by the Siennese and Perugian ambassadors and by Simone da Battifolle. The priori were reduced to 8 (2 popolani grossi, 3 mediasti and 3 artifici miniati), while the gonfaloniere was to be chosen in turn from each of those classes; the grandi were excluded from the administration, but they were still admitted to the consiglio del comune, the cinque di mercedia, and other offices pertaining to the commune; the Ordinamenti were maintained but in a somewhat attenuated form, and certain grandi as a favour were declared to be of the popolo. Florence was now a thoroughly democratic and commercial republic, and its whole policy was mainly dominated by commercial considerations: its rivalry with Pisa was due to an ambition to gain secure access to the sea; its strong Guelphism was the outcome of its determination to secure the bank-business of the papacy, and its desire to extend its territory in Tuscany to the necessity for keeping open the land trade routes. Florentine democracy, however, was limited to the walls of the city, for no one of the comito nor any citizen of the subject towns enjoyed political rights, which were reserved for the inhabitants of Florence alone and not by any means for all of them.

Florence was in the 14th century a city of about 100,000 inhabitants, of whom 25,000 could bear arms; there were 110 churches, 39 religious houses; the shops of the arti Statisca della lana numbered over 200, producing cloth worth 1,200,000 florins; Florentine bankers and merchants were found all over the world, often occupying responsible positions in the service of foreign governments; the revenues of the republic, derived chiefly from the city customs, amounted to some 300,000 florins, whereas its ordinary expenses, exclusive of military matters and public buildings, were barely 40,000. It was already a centre of art and letters and full of fine buildings, pictures and libraries. But now that the grandi were suppressed politically, the lowest classes came into prominence, "adventurers without sense or virtue and of no authority for the most part, who had usurped public offices by illicit and dishonest practices" (Matteo Villani, iv. 60); this paved the way for tyranny.

In 1347 Florence was again stricken with famine, followed the next year by the most terrible plague it had ever experienced, which carried off three-fifths of the population (according to
Villani). Yet in spite of these disasters the republic was by no means crushed; it soon regained the suzerainty of many cities which had broken off all connexion with it after the expulsion of the duke of Athens, and subsequently purchased the overlordship of Prague from Queen Joanna of Naples, who had inherited it from the duke of Calabria. In 1351 Giovanni Visconti, lord and archbishop of Milan, having purchased Bologna and allied himself with sundry Ghibelline houses of Tuscany with a view to dominating Florence, the city made war on him, and in violation of its Guelph traditions placed itself under the protection of the emperor Charles IV. (1355) for his lifetime. This move, however, was not popular, and it enabled the grandi, who, although excluded from the chief offices, still dominated the parte Guelfa, to reassert themselves. They had in 1347 succeeded in enacting a very stringent law against all who were in any way tainted with Ghibellinism, which, they themselves being above suspicion in that connexion, enabled them to drive from office many members of the popolo minuto. In 1358 the parte Guelfa made these enactments still more stringent, punishing with death or heavy fines all who being Ghibellines held office, and provided that if trustworthy witnesses were forthcoming condemnations might be passed for this offence without hearing the accused; even a non-proved charge or an ammonitio (warning not to accept office) might be sufficient. Thus the parte, represented by its 6 (afterwards 9) captains, came to exercise a veritable reign of terror, and no one knew when an accusation might fall on him. The leader of the parte was Piero degli Alibizzi, whose chief rivals were the Ricci family.

Italy at this time began to be overrun by bands of soldiers of fortune. The first of these bands with whom Florence came into contact was the Great Company, commanded by the count of Lando, which twice entered Tuscany but was expelled both times by the Florentine troops (1358-1359).

In 1362 we find Florence at war with Pisa on account of commercial differences, and because the former had acquired the lordship of Volterra. The Florentines were successful until Pisa enlisted Sir John Hawkwood's English company; the latter won several battles, but were at last defeated at Cascina, and peace was made in 1364, neither side having gained much advantage. A fresh danger threatened the republic in 1369 when Charles IV., who had allied himself with Pope Urban V., Queen Joanna of Naples, and various north Italian despots to humiliate the Visconti, demanded that the power of the Florentines should join the league. They refused to do so and armed themselves for defence, but eventually satisfied the emperor with a money payment.

The tyranny of the parte Guelfa still continued unabated, and the copiani carried an enactment by which no measure affecting the parte should be even discussed by the signory unless previously approved of by them. This infamous law, however, aroused such opposition that some of the very men who had proposed it assembled in secret to discuss its abolition, and a quarrel between the Alibizzi and the Ricci having weakened the parte, a balia of 56 was agreed upon. Several of the Alibizzi and the Ricci were excluded from office for five years, and a council called the Ten of Liberty was created to defend the laws and protect the weak against the strong. The parte Guelfa and the Alibizzi still remained very influential and the attempts to abolish admonitions failed.

In 1375 Florence became involved in a war which showed how the old party divisions of Italy had been obliterated. The papal legate at Bologna, Cardinal Guillaume de Noënet (d. 1376), although the church was then subjected to Florence, was meditating the annexation of the city to the Holy See; he refused a request of the Florentines for grain from Romagna, and authorized Hawkwood to devastate their territory. Although a large part of the people disliked the idea of a conflict with the church, an alliance with Florence's old enemy Benaffi Visconti was made, war declared, and a balia of 8, the Otto della guerra (afterwards called the "Eight Saints" on account of their good management) was created to carry on the campaign. Treaties with Pisa, Siena, Arezzo and Cortona were concluded, and soon no less than 80 towns, including Bologna, had thrown off the papal yoke. Pope Gregory XI. placed Florence under an interdict, ordered the expulsion of all Florentines from foreign countries, and engaged a ferocious company of Bretons to invade the republic's territory. The Eight levied heavy toll on church property and ordered the priests to disregard the interdict. They turned the tables on the pope by engaging Hawwoodd, and although the Bretons by order of Cardinal Robert of Geneva (afterwards the anti-pope Clement VII.) committed frightful atrocities in Romagna, their captains were bribed by the republic not to molest its territory. By 1378 peace was made, partly through the mediation of St. Catherine of Siena, and the interdict was removed in consideration of the republic's paying a fine of 200,000 florins to the pope.

During the war the Eight had been practically rulers of the city, but now the parte Guelfa, led by Lapo da Castiglionechio and Piero degli Alibizzi, attempted to reassert itself by illicit interference in the elections and by a liberal use of "admonitions" ("ammonizioni"). Salvestro de' Medici, who had always opposed the parte, having been elected gonfaloniere in spite of its intrigues, proposed a law for the abolition of the admonitions, which was eventually passed (June 18, 1358), but the people had been aroused, and desired to break the power of the parte for good. Rioting occurred on the 21st of June, and the houses of the Alibizzi and other nobles were burnt. The signory meanwhile created a balia of 80 which repealed some of the laws promulgated by the parte, and partly enfranchised the ammoniti. The people were still unsatisfied, the arti minori demanded further privileges, and the workmen insisted that their grievances against the arti maggiori, especially the wool trade by whom they were employed, had not been redressed. A large party therefore gathered outside the city and conspired to subvert the signory and establish a popular government. The riot of the ciompi (1378). Although the plot, in which Salvestro does not seem to have played a part, was revealed, a good deal of mob violence occurred, and on the 21st of July the populace seized the podestà's palace, which they made their headquarters. They demanded a share in the government for the popolo minuto, but as soon as this was granted Tommaso Strozzi, as spokesman of the ciompi, obliged the signory to resign their powers to the Eight. Once the people were in possession of the palace, a ciompo named Michele di Lando took the lead and put a stop to disorder and pillage. He reigned master of Florence for one day, during which he reformed the constitution, probably with the help of Salvestro de'Medici. Three new guilds were created, and nine priors appointed, three from the arti maggiori, three from the minori, and three from the new ones, while each of these classes in turn was to choose the gonfaloniere of justice; the first to hold the office was Michele di Lando. This did not satisfy the ciompi, and the disorders provoked by them resulted in a new government which reformed the two councils so as to exclude the lower orders. But to satisfy the people several of the grandi, including Piero degli Alibizzi, were put to death, on charges of conspiracy, and many others were exiled. There was perpetual rioting and anarchy, and interference in the affairs of the government by the working men, while at the same time poverty and unemployment increased owing to the timidity of capital and the disorders, until at last in 1382 a reaction set in, and order was restored by the guild companies. Again a new constitution was established, which was that of the ciompi and the other half of the minori; on several other boards the former were to be in the majority, and the three new guilds were abolished. The demagogues were executed or forced to fly, and Michele di Lando with great ingratitude was exiled. Several subsequent risings of the ciompi, largely of an economic character, were put down, and the Guelph families gradually regained much of their lost power, of which
they availed themselves to exclude their opponents and revive the odious system of ammosidion.

Meanwhile in foreign affairs the republic maintained its position, and in 1385 it regained Arezzo by purchase from the lieutenant of Charles of Durazzo. In 1390 Gian Galeazzo Visconti, having made himself master of a large part of northern Italy, intrigued to gain possession of Pisa and Siena. Florence, alone in resisting him, engaged Hawkwood, who with an army of 7000 men more than held his own against the powerful lord of Milan, and in 1392 a peace was concluded which the republic strengthened by an alliance with Pisa and several north Italian states. In 1393 Maso degli Albizzi was made gonfaloniere, and for many years remained almost master of Florence owing to his influence in the Arte della Lana. A severe persecution was initiated against the Alberti and other families, who were disfranchised and exiled. Disorders and conspiracies against the merchant oligarchy continued, and although they were unsuccessful, the passion was incredibly bitter, and the exiles caused the republic much trouble by intriguing against it in foreign states. In 1397-1398 Florence had two more wars with Gian Galeazzo Visconti, who, aspiring to the conquest of Tuscany, acquired the lordship of Pisa, Siena and Perugia. Hawkwood being dead, Florence purchased aid from the emperor Rupert. The Imperialists were beaten; but just as the Milanese were about to march on Florence, Visconti died. His territories were then divided between his sons and his condottieri, and Florence, ever keeping her eye on Pisa, now ruled by Gabriele Maria Visconti, made an alliance with Pope Boniface IX., who wished to regain Perugia and Bologna. War broke out once more, and the allies were successful, but as soon as Boniface had gained his ends he made peace, leaving the Florentines unsatisfied. In 1404 their attempt to capture Pisa single-handed was failed, and Gabriele Maria placed himself under the protection of the French king. The Florentines then marched to Rome, who supported the anti-popes all through the great schism, and suggested that they too would support the then anti-pope, Benedict XIII., in exchange for the sale of Pisa. This was agreed to, and in 1405 the city was sold to Florence for 250,000 florins; and Gino Capponi, 1 the Florentine commissioner, took possession of the citadel, but a few days later the citizens arose in arms and recaptured it from the mercenaries. There was great consternation in Florence at the news, and every man in the city "determined that he would go naked rather than not conquer Pisa." (G. Capponi). The next year that city, then ruled by Giovanni Guidaccia, was besieged by the Florentines, who blockaded the mouth of the Arno. After a six months' siege Pisa surrendered on terms (10th October 1406), and, although it was not sacked, many of the citizens were exiled and others forced to live in Florence, a depopulation from which it never recovered. Florence now acquired a great seaport and was at last able to develop a direct maritime trade.

Except in connexion with the Pisan question the republic had taken no definite side in the great schism which had divided the church since 1378, but in 1408 she appealed both to Pope Gregory XII. and the anti-pope Benedict XIII. as well as to various foreign governments in favour of a settlement, and suggested a council within her own territory. Gregory refused, but after consulting a committee of theologians who declared him to be a heretic, the council promoted by Cardinal Cossa and other independent prelates met at Pisa. This nearly led to war with King Ladislas of Naples, because he had seized Rome, which he could only hold so long as the church was divided. The council deposed both popes and elected Pietro Filargi as Alexander V. (26th of June).

But Ladislas still occupied the papal states, and Florence, alarmed at his growing power and ambition, formed a league with Siena, Bologna and Louis of Anjou who laid claim to the Neapolitan throne, to drive Ladislas from Rome. Cortona, Orvieto, Viterbo and other cities were recovered for Alexander, and in January 1410 Rome itself was captured by the Florentines under Malatesta dei Malatesti. Alexander having died in May before entering the Eternal City, Cardinal Cossa was elected as John XXIII.; Florence without offering him made peace with Ladislas, who had ceased to be dangerous, and purchased Cortona of the pope. In 1413 Ladislas attacked the papal states once more, driving John from Rome, and threatened Florence; but like Henry VII., Gian Galeazzo Visconti, and other enemies of the republic, he too died most opportunely (6th of August 1414). John having lost all authority after leaving Rome, a new council was held at Constance, which put an end to the schism in 1417 with the election of Martin V. The new pope came to Florence in 1419 as he had not yet regained Rome, which was held by Francesco Sforza for Queen Joanna II. of Naples, and remained there until the following year.

No important changes in the constitution took place during this period except the appointment of two new councils in 1411 to decide on questions of peace and war. The aristocratic faction headed by Maso degli Albizzi, a wise and popular statesman, had remained predominant, and at Maso's death in 1417 he was succeeded in the leadership of the party by Niccolò da Uzzano. In 1421 Giovanni de' Medici was elected gonfaloniere of justice, an event which marks the beginning of that wealthy family's power. The same year the republic purchased Leghorn from the Genoese for 100,000 florins, and established a body of "Consuls of the Sea" to superintend maritime trade. Although 11,000,000 florins had been spent on recent wars Florence continued prosperous and its trade increased.

In 1421 Filippo Maria Visconti, who had succeeded in reconquering most of Lombardy, seized Forli; this induced the Florentines to declare war on him, as they regarded his approach as a menace to their territory in spite of the opposition of the peace party led by Giovanni de' Medici. The campaign was anything but successful, and the Florentines were defeated several times, with the result that their credit was shaken and several important firms failed. The pope too was against them, but when they induced the Venetians to intervene the tide of fortune changed, and Visconti was finally defeated and forced to accept peace on onerous terms (1427).

The old systems of raising revenue no longer corresponded to the needs of the republic, and as early as 1336 the various loans made to the state were consolidated into one national debt (monte). Subsequently all extraordinary expenditure was met by forced loans (prestanze), but the method of distribution aroused discontent among the lower classes, and in 1427 a general catastro or assessment of all the wealth of the citizens was formed, and measures were devised to distribute the obligations according to each man's capacity, so as to avoid pressing too heavily on the poor. The catastro largely the work of Giovanni de' Medici, who greatly increased his popularity thereby. He died in 1429. An attempt to capture Lucca led Florence, in alliance with Venice, into another costly war with Milan (1432-1433). The mismanagement of the campaign brought about a quarrel between the aristocratic party, led by Rinaldo degli Albizzi, and the popular party, led by Giovanni de' Medici's son Cosimo (1386-1464), although both had agreed to the war before it began. Rinaldo was determined to break the Medici party, and succeeded in getting Cosimo exiled. The Albizzi tried to strengthen their position by conferring exceptional powers on the capitano del popolo and by juggling with the election bags, but the Medici still had a great hold on the populace. Rinaldo's proposal for a coup d'état met with no response from his own party, and he failed to prevent the election of a pro-Medici signory in 1434. He and other leaders of the party were summoned to the palace to answer a charge of plotting against the state, to which he replied by collecting 800 armed men and was only avenged through the intervention of Pope Eugenius IV., who was then in Florence. A parlamento was summoned, and the ballia appointed decreed
the return of Cosimo and the exile of Rinaldo degli Albizzi, Rodolfo Peruzzi, Niccolò Barbarodi, and others, in spite of the feeble attempt of Eugenius to protect them. On the 9th of October, 1454, Cosimo returned to Florence, and for the next three centuries the history of the city is identified with that of the house of Medici. Cosimo succeeded in dominating the republic while remaining nominally a private citizen. He exiled those who opposed him, and governed by means of the balle, which, re-elected every five years, appointed all the magistrates and acted according to his orders. In 1437 Florence and Venice were again at war with the Visconti, whose chief captain, Niccolò Piccinino (q.v.), on entering Tuscany with many Florentine exiles, his troops was signally defeated at Anghiari by the Florentines under Francesco Sforza (1440); peace was made the following year. The system of the catasto, which led to abuses, was abolished, and a progressive income-tax (decima scalata) was introduced with the object of lightening the burdens of the poor, who were as a rule Medicean, at the expense of the rich; but as it was frequently increased the whole community came to be oppressed by it in the end. Cosimo increased his own authority and that of the republic by aiding Francesco Sforza to become duke of Milan (1450), and he was in fact himself aspired to by the Venetians (1452-1454). In 1452 the emperor Frederick III. passed through Florence on his way to be crowned in Rome, and he was received as a friend. During the last years of Cosimo's life, affairs were less under his control, and the gonfaloniere Luca Pitti, a vain and ambitious man, introduced many changes, such as the abasement of the authority of the podestà and of the capitano, which Cosimo desired but was glad to attribute to others.

In 1464 Cosimo died and was succeeded, not without some opposition, by his son Piero, who was very infirm and gouty. Various plots against him were hatched, the anti-Medician faction being called the Del Poggio party because the house of its leader Luca Pitti was on a hill, while the Mediceans were called the Del Piano party because Piero's house was in the town below; the other opposition leaders were Deticsalvi Neroni and Agnolo Acciaiuoli. But Piero's unexpected energy upset the schemes of his enemies. The death of Sforza led to a war for the succession of Milan, and the Venetians, instigated by Florentine exiles, invaded Tuscany. The war ended in an indefinite armistice, signed in 1466, through the intervention of Pope Paul II. Piero died in 1469, leaving two sons, Lorenzo (1449-1492) and Giuliano (1455-1478). The former at once assumed the reins of government and became ruler of Florence in a way neither Cosimo nor Piero had ever attempted; he established his domination by means of balle consisting of the signory, the accoppiatori, and 240 other members, all Medicians, to be renewed every five years (1471). In 1472 a quarrel having arisen with Volterra on account of a dispute concerning the alum mines, Lorenzo sent an expedition against the city, which was sacked and many of the inhabitants massacred. Owing to a variety of causes an enmity arose between Lorenzo and Pope Sixtus IV., and the latter, if not an accomplice, at all events had knowledge of the Pazzi conspiracy against the Medici (1478). The result of the plot was that, although Giuliano was murdered, Lorenzo strengthened his position, and put to death or exiled numbers of his enemies. He was excommunicated by Sixtus, who, together with King Ferdinand of Naples, waged war against him; no great successes were registered on either side at first, but eventually the Florentines were defeated at Poggio Imperiale (near Poggibonsi) and the city itself was in danger. Lorenzo's position was critical, but by his boldness in going to Naples he succeeded in concluding a peace with the king, which led to a reconciliation with the pope (1479-1480). He was received with enthusiasm on returning to Florence and became absolute master of the situation. In April 1480 a bolla was formed, and its most important act was the creation at Lorenzo's instance of the Council of Seventy: it was constituted for five years, but it became permanent, and all its members were Lorenzo's friends. From that time until his death the city was free from party strife under a de facto despotism, but after the Rinuccini conspiracy of that year the Council of Seventy passed a law declaring attempts on Lorenzo's life to be high treason. Owing to his political activity Lorenzo had neglected the business interests of his firm, and in order to make good certain heavy losses he seems to have appropriated public funds. His foreign policy, which was magnificent but expensive, rendered further forced loans necessary, and he placed himself on the side of the French. On the 6th of November at the head of 12,000 men, in spite of their French sympathies the citizens were indignant at the seizure of Sársana, and when they gave the king a splendid welcome, they did not like his attitude of conqueror. Charles was impressed with the wealth and refinement of the citizens, and above all with the solid fortress-like appearance of their palaces. The signory appointed Piero Capponi, a man of great ability and patriotism, and experienced in diplomacy, the gonfaloniere Francesco Valori, the Dominican Giorgio Vespucci, and the jurisconsult and diplomatist Domenico Bonsi, Lorenzo the Magnificent.

Piero de' Medici

Piero de' Medici (the Goaty).

Florence Expulsion of the Medici (1494).

Charles VIII. in Florence.
Savonarola conduct against a conquer war, party the his them the death; anrf snivellers, The actual discussions to having Savonarola’s money the tried over so) the syndics refused to accept it. The king said in a threatening tone, “Then we shall sound our trumpets,” whereupon Capponi tore up the document in his face and replied, “And we shall ring our bells.” The king, realizing what street fighting in Florence would mean, at once came to terms; he contented himself with 120,000 florins, agreeing to assume the title of “Protector and Restorer of the liberty of Florence,” and to give up the fortresses he had taken within two years, unless his expedition to Naples should be concluded sooner; the Medici were to remain banished, but the price on their heads was withdrawn. But Charles would not depart, a fact which caused perpetual disturbance in the city, and it was not until the 28th of November, after an exhortation by Savonarola whom he greatly respected, that he left Florence.

It was now intended to re-establish the government on the basis of the old republican institutions, but it was found that sixty years of Medici rule had reduced them to mere shadows, and the condition of the government, largely controlled by a balia of 20 accoppiatori and frequently disturbed by the summoning of the parlamento, was utterly chaotic. Consequently men talked of nothing save of changing the constitution, but unfortunately there was no longer an upper class accustomed to public affairs, while the lower class was thoroughly demoralized. Many proposals were made, none of them of practical value, until Savonarola, who had already made a reputation as a moral reformer, began his famous series of political sermons. In the prevailing confusion the people turned to him as their only hope, and gradually a new government was evolved, each law being enacted as the result of his exhortations. A Greater Council empowered to appoint magistrates and pass laws was formed, to which all citizens noti di specchio (who had paid their taxes) and beneficiari (i.e., who had sat in one of the higher magistracies or whose fathers, grandfathers, or great-grandfathers had done so) were eligible together with certain others. There were 3300 such citizens, and they sat one-third at a time for six months. The Greater Council was to elect another council of 80 citizens over forty years old, also to be changed every six months; this body, which the signori must consult once a week, together with the council and the syndics, was to appoint ambassadors and commissaries of war, and deal with other confidential matters. The system of forced loans was abolished and a 10% tax on real property introduced in its stead, and a law of amnesty for political offenders enacted. Savonarola also proposed a court of appeal for criminal and political crimes tried by the Otto di guardia e balia; this too was agreed to, but the right of appeal was to be, not to a court as Savonarola suggested, but to the Greater Council, a fact-which led to grave abuse, as judicial decisions became the arbiters of political questions. The portasini were abolished and a monte di pieta to advance money at reasonable interest was created. But in spite of Savonarola’s popularity there was a party called the Bigi (greys) who intrigued secretly in favour of the return of the Medici, while the men of wealth, called the Arrabbiati, although they hated the Medici, were even more openly opposed to the actual régime and desired to set up an aristocratic oligarchy.

The adherents of Savonarola were called the Piagnoni, or snivellers, while the Neutrali changed sides, as judiciously as the weather, and the Opportunists, or Medicei, being between the hammer and the anvil, would presently be crushed. A league between the pope, consultor, Venice and Spain having been made against Charles VIII., the latter was forced to return to France. On his way back he passed through Florence, and, although the republic had refused to join the league, it believed itself in danger, as Piero de’ Medici was in the king’s train. Savonarola was again sent to the French camp, and his eloquence turned the king from any idea he may have had of reinstating the Medici. At the same time Charles violated his promise by giving aid to the Pisans in their revolt against Florence, and did not restore the other fortresses. After the French had abandoned Italy, Piero de’ Medici, encouraged by the league, enlisted a number of mercenaries and marched on Florence, but the citizens, fired by Savonarola’s enthusiasm, flew to arms and prepared for an energetic resistance; owing to Piero’s incapacity and the exhaustion of his funds the expedition came to nothing. At the same time the conditions of the city were not prosperous; its resources were strained by the sums paid to Charles and by the war; its credit was shaken, its trade paralysed, and plague visited the city, and the war to subjugate Pisa was proceeding unsatisfactorily. Worse still was the death in 1496 of one of its ablest and most disinterested statesmen, Piero Capponi. The league now attacked Florence, for Pope Alexander VI. hated Savonarola and was determined to destroy the republic, so as to re-establish the Medici temporarily. The enemy was strengthened by the Venetians and Imperialists besieged Leghorn, and there was a great misery in Florence. All this decreased Savonarola’s popularity to some extent, but the enemy having been beaten at Leghorn and the league being apparently on the point of breaking up, the Florentines took courage and the friar’s party was once more in the ascendant. Numerous processions were held, Savonarola’s sermons against corruption and vice seemed to have had some effect, and the carnival of 1497 again famous for the burning of the “vanities” (i.e., indecent books and pictures and carnival masks and costumes). The friar’s sermons against ecclesiastical corruption, and especially against the pope, resulted in his excommunication by the latter, in consequence of which he lost much of his influence and immorality spread once more. That same year Piero made another unsuccessful attempt on Florence. New Medici plots having been discovered, Bernardo del Nero and other prominent citizens were tried and put to death; but the party hostile to Savonarola gained ground and had the support of the Franciscans, who were hostile to the Dominican order. Pulpit warfare was waged between Savonarola and his opponents, and the matter ended in his being forbidden to preach and in a proposed ordeal by fire, which, however, never came off. The pope again and again demanded that the friar be surrendered to him, but without success, in spite of his threats of an interdict against the city. The Piagnoni were out of power, and a signory of Arrabbiati having been elected in 1498, a mob of Savonarola’s opponents attacked the convent of St. Giovannina and killed the friar, and he himself was arrested and imprisoned. The commissary appointed to try him on charges of heresy and treason was composed of his enemies, including Doffo Spini, who had previously attempted to murder him; many irregularities were committed during the three trials, and the prisoner was repeatedly tortured. The outgoing signory secured the election of another which was of their way of thinking, and on the 22nd of May 1498 Savonarola was condemned to death and executed the following day.

The pope having been satisfied, the situation in Florence was less critical for the moment. The war against Pisa was renewed, and in 1499 the city might have been taken but for the dilatory tactics of the Florentine commander Paolo Vitelli, who was consequently arrested on a charge of treason and put to death. Louis XII. of France, who now sent an army into Italy to conquer the Milanese, obtained the support of the Florentines. Cesare Borgia, who had seized many cities in Romagna, suddenly demanded the reinstatement of the Medici in Florence, and then changed sides, attacking him by pointing him captain-general of the Florentine forces at a large salary (1501). The weakness of the government becoming every day more apparent, several constitutional changes were made, and many old institutions, such as that of the podestà and capitanio del popolo, were abolished; finally in 1502, in order
Florence being of propulsion threw was Malatesta large internal A to play under in Medici to expulsion Second supported Giuliano was Pisa, but meanwhile militia appointment. 538 give Cardinal of the city, the militia with Passerini's and suggested ra (i7th Niccolo de' Capponi of Florence, who proved unequal influence and scales above his headway in the city). After some unexpected, he entered the city, and Cardona, by appointed a new factional government, was appointed to the city, and Cardona's new terms were accepted, viz. the readmission of the Medici, a fine of 150,000 florins, and an alliance with Spain. On the 1st of September 1512 Giuliano and Giovanni de' Medici, and their nephew Lorenzo, entered Florence with the Spanish troops; a parlamento was summoned, and a packed balta formed which abolished the Greater Council and created a constitution similar to that of Lorenzo the Magnificent. Giuliano became de facto head of the government, but he did not pursue the usual vindictive policy of his house, although he resorted to the Laurentian method of amusing the citizens with splendid festivities. In 1513, on the death of Julius II, Giovanni de' Medici was elected pope as Leo X, an event which greatly enhanced the importance of the house. In March 1514 Giuliano died, and was succeeded by Lorenzo, who was also created duke of Urbino. At his death in 1519 Cardinal Giulio de' Medici (son of the Giuliano murdered in the Pazzi conspiracy) took charge of the government; he met with some opposition and had to play off the Ottimati against the Pianghi, but he did not rule badly and maintained at all events the outward forms of freedom. In 1523 he was created pope as Clement VII. and sent his relatives Ippolito and Alessandro, both minors and bastards, to Florence under the tutelage of Cardinal Silvio Passerini. Ippolito was styled the Magnifico and destined to be ruler of the republic, but Cardinal Passerini's regency proved most unpopular, and the city was soon seething with discontent. Revolts broke out and Passerini showed himself quite unequal to coping with the situation. The Ottimati were mostly anti-Medicean, and by 1527 the position was untenable. When Passerini, Ippolito and all his wife, threw their influence in the scales against the Medici, and the magistrates declared for their expulsion from power, Passerini, Ippolito and Alessandro left Florence (17th of May 1527). A Consiglio degli Sceti was summoned, and a constitution similar to that of Savonarola's time was established. The Greater Council was revived and Niccolò Capponi created gonfaloniere for a year. But Florence was torn by factions—the Ottimati who desired an oligarchy, the Pallesechi or Mediceans who generally supported them, the Adrati who opposed Capponi for his moderation, the Arrabbiati who were strongly anti-Medicean, and the Popolani who opposed the Ottimati. "It is almost impossible that a state so disorganized and corrupt as Florence then was should produce men of parts and character, but if by chance any such should arise they would be hated and persecuted, their dispositions would be soured by indignation, or they would be hunted from their country or die of grief" (Benedetto Varchi). Capponi did his best to reform the city and save the situation, and while adopting Savonarola's tone in internal matters, he safeguarded the Medicean party, realized that a reconciliation between the papal arm and the Republic was not to be hoped for, a siege for a siege, but a large part of the people were against him, either from Medicean sympathies or fear, although the Frateschi, as the believers in Savonarola's views were called, supported him strongly. A body called the Nove della Milizia, of whom Michelangelo Buonarroti was a member, was charged with the defence of the city, and Michelangelo (q.v.) himself superintended the strengthening of the fortifications. A most unfortunate choice for the chief command of the army was the appointment of Malatesta Baglioni. In August an imperial army under Phillibert, prince of Orange, advanced on the city. In September Malatesta surrendered Perugia, and other cities fell before the Imperialists. All attempts to come to terms with the pope were unsuccessful, and by October the siege had begun. Although alone against papacy and empire, the citizens showed the greatest spirit and devotion, and were successful in many sorties. The finest figure produced by these events was that of Francesco Ferruccio (q.v.); by his defence of Empoli he showed himself a first-class soldier, and was appointed commissioner-general. He executed many rapid marches and counter-marches, assaulting isolated bodies of the enemy unexpectedly, and harassing them continually. But Malatesta was a traitor at heart and hindered the defence of the city in every way. Ferruccio, who had recaptured Volterra, marched to Gavianna above Pistoia to attack the Imperialists in the rear. A battle took place at that spot on the 3rd of August, but in spite of Ferruccio's heroism he was defeated and killed; the prince of Orange also fell in that desperate engagement. Malatesta contributed to the defeat by preventing a simultaneous attack by the besieged. The sufferings from famine within the city were now very great, and an increasingly large part of the people favoured surrender. The signory, at last realizing that Malatesta was a traitor, dismissed him; but it was too late, and he now behaved as though he were governor of Florence; when the troops attempted to enforce the dismissal he turned his guns on them. On the 9th of August the signory saw that all hope was lost and entered into negotiations with Don Ferrante Gonzaga, the new imperial commander. On the 12th the capitulation was signed: Florence was to pay an indemnity of 80,000 florins, the Medici were to be recalled, the emperor was to establish the new government, "it being understood that liberty is to be preserved." Baccio Valori, a Medicean who had been in the imperialist camp, now took charge, and the city was occupied by foreign troops. A parlamento was summoned, the usual packed balta created, and all opposition silenced. The city was given over to Pope Clement, who, disregarding the terms of the capitulation, had Carducci and Girolami (the last gonfaloniere) hanged, and established Alessandro de' Medici, the natural son of Lorenzo, duke of Urbino, as head of the republic on the 3rd of July 1531. The next year
FLORES—FLORIAN

539

the signory was abolished, Alessandro created gonfaloniere for life, and his lordship made hereditary in his family by imperial patent. Thus Florence lost her liberty, and came to be the capital of the duchy (afterwards grand-duchy) of Tuscany (see TUSCANY). The Medici dynasty ruled in Tuscany until the death of Gian Gastone in 1382. The grand-duchy was annexed to the French crown by the marriage of Maria Theresa on her son Peter Leopold. During the Napoleonic wars the grand-duke Ferdinand III. of Habsburg-Lorraine was driven from the throne, and Tuscany was annexed to the French empire in 1808. In 1815 Florence was made capital of the kingdom of Etruria, but after the fall of Napoleon in 1814 Ferdinand was reinstated. He died in 1833, and was succeeded by Leopold II. In 1848 there was a liberal revolutionary movement in Florence, and Leopold granted a constitution. But civil disorders followed, and in 1849 the grand-duke returned under an Austrian escort. In 1859, after the Franco-Italian victories over the Austrians in Lombardy, by a bloodless revolution in Florence Leopold was expelled and Tuscany annexed to the Sardinian kingdom.

In 1866 Florence became the capital of the kingdom of Italy, but after the occupation of Rome in 1870 during the Franco-Prussian war, the capital was transferred to the Eternal City (1871).

BIBLIOGRAPHY.—The best complete history of Florence is Gino Capponi's *Storia della Repubblica di Firenze* (2 vols., Florence, 1875), which although defective as regards the earliest times is a standard work. The best modern histories of Florence are: F. Perinetti, *Italia in Firenze* (9 vols., Paris, 1877-1890). For the early period see Pasquale Villari's *I Primi Due Secoli della storia di Firenze* (Eng. ed., London, 1894), and R. Davidson's *Geschichte der Stadt Florenz* (Berlin, 1896); P. Villari's *Savonarola elegante* (London, 1876) is invaluable for the period during which the friar's personality dominated Florence, and his *Machiavelli* (English ed., London, 1892) must be also consulted, especially for the development of political theories. Among the English histories of Florence, Napier's *Florentine History* (6 vols., London, 1846-1847) and A. Trollope's *History of the Commonwealth of Florence* (4 vols., London, 1865) are not without value, although out of date. Francis Hyett's *Florence* (London, 1900) is more recent and comprehensive; the author is somewhat Medicean in his views, and frequently inaccurate. For the later history, A. von Reumont's *Geschichte von Toscania* (Gotha, 1876-1877) is one of the best works. There is a large number of small treatises and compendia of Florentine history of the guide-book description. See also the bibliographies in Medic, Machiavelli, Savonarola, Tuscany, &c.

*The Moors,* an island in the Atlantic Ocean, belonging to Portugal, and forming part of the Azores archipelago. Pop. (1900) 8137; area, 57 sq. m.Flores and the adjacent island of Corvo (pop. 806; area, 7 sq. m.) constitute the westernmost group of the Azores, and seem but imperfectly to belong to the archipelago, from the rest of which they are widely severed. They lie also out of the usual track of navigators; but to those who, missing their course, are led thither, Flores affords good shelter in its numerous bays. Its poultry is excellent; and the cattle are numerous, but small. It derives its name from the abundance of the flowers that find shelter in its deep ravines. Its capital is Santa Cruz das Flores (2247). In 1591 Flores was the station of the English fleet before the famous sea fight between Sir R. Grenville's ship "Revenge" and a Spanish fleet of 53 vessels. See AZORES.

*Flores,* an island of the Dutch East Indies, a member of the chain extending east of Java. Its length is 224 m., its greatest breadth 37 m., and its area 850 sq. m. The existence of chalk, and sandstone, eruptive rock, volcanoes and heights stretching west and east, indicates a similar structure to that of the other islands of the chain. Several volcanoes are active. Among the loftier summits are, on the south coast, Gunong Rokka (7940 ft.) and Koe (6960 ft.); with the lesser but constantly active Gunong Api, forming a peninsula; and at the south-east, Lobotobi (7120 ft.). The thickly wooded interior is little explored. The coasts have deep bays and extensive rounded gulfs, which are situated the principal villages (see PONI).

On the north coast are Bari, Reo, Maunier and Gelingit; on the east, Laranjuta; and on the south, Sikka and Ende.

The rivers, known only at their mouths, seem to be un navigable. The mean temperature is 77° to 80° F., and the yearly rainfall 43 to 47 in. For administrative purposes the island is divided into West Flores (Mangerais), attached to the government of Celebes, and Middle and East Flores (Larantuka and dependencies), attached to the residency of Ternate. The population is estimated at 250,000. The people live by trade, fishing, salt-making, shipbuilding, and the cultivation of rice, maize, and palms in the plain, but there is little industry or commerce. Some edible birds' nests, rice, sandalwood and cinnamon are exported to Celebes and elsewhere. The inhabitants of the coast-districts are mainly of Malay origin. The aborigines, who occupy the interior, are of Papuan stock. They are tall and well-built, with dark or black skins. The hair is frizzly. They are pure savages; their only religion is a kind of nature-worship. They consider the earth holy and inviolable; thus in severe droughts they only dig the river-beds for water as a last resource. Portugal claimed certain portions of the island until 1859.

FLOREZ, ENRIQUE (1701-1773), Spanish historian, was born at Valladolid on the 14th of February 1701. In his fifteenth year he entered the order of St Augustine, was afterwards professor of theology at the university of Alcala, and published a *Cursus theologiae in five volumes (1735-1738).* He afterwards devoted himself to historical studies. Of these the first-fruits was his *Clave Historic*, a work of the same class as the French *Art de verifier les dates,* and preceding it by several years. It appeared in 1743, and passed through many editions. In 1747 was published the first volume of *España Sagrada, teatro geográfico-histórico de la Iglesia de España,* a vast compilation of Spanish ecclesiastical history which obtained a European reputation, and of which twenty-nine volumes appeared in the author's lifetime. It was continued after his death by Manuel Risco and others, and further additions have been made at the expense of the Spanish government. The whole work in fifty-one volumes was published at Madrid (1747-1886). Its value is considerably increased by the insertion of ancient chronicles and documents not easily accessible elsewhere. Florez was a good numismatist, and published *Medallas de las Conquistas* in 2 vols. (1757-1758), of which a third volume appeared in 1773. His last work was the *Memorias de las reynas Católicas,* 2 vols. (1776). Florez led a retired, studious and unambitious life, and died at Madrid on the 20th of August 1773.

See F. Mendez, *Noticia de la vida y escritos de Henrique Florez* (Madrid, 1780).

FLOREY, SANT, a martyr honoured in Upper Austria. In the 8th century Puchow was mentioned as the place of his tomb, and on the site was built the celebrated monastery of canons regular, St Florian, which still exists. His Acta are of considerable antiquity, but devoid of historical value. Their substance is borrowed from the *Acta of St Irenaeus of Strimium.* The cult of St Florian was introduced into Poland, together with the relics of the saint, which were brought thither in 1183 by Giles, bishop of Modena. Casimir, duke of Poland, dedicated a church at Krakow to him. He is represented in various ways, especially as a warrior holding in his hand a vessel from which he pours out flames. His protection is often sought against fire. His day in the calendar is the 4th of May.

FLOREY, JEAN PIERRE CLARIS DE (1775-1794), French poet and romance writer, was born on the 6th of March 1755 at the château of Florían, near Sauve, in the department of Gard. His mother, a Spanish lady named Gillette de Salgues, died when he was quite a child. His uncle and guardian, the marquis of Florían, who had married a niece of Voltaire, introduced him at Ferney and in 1768 he became page at Anet in the household of the duke of Penthièvre, who retained his friend throughout his life. Having studied for some time at the artillery school at Bapaume he obtained from his patron a captain's commission in a dragoon regiment, and in this capacity it is said he displayed
a boisterous behaviour quite incongruous with the gentle, meditative character of his works. On the outbreak of the French Revolution he retired to Sceaux, but he was soon discovered and imprisoned; and though his imprisonment was short he survived his release only a few months, dying on the 13th of September 1794.

Florian's first literary efforts were comedies; his verse epistle Voltaire et le serf du Mont Jura and an eclogue Ruth were crowned by the French Academy in 1782 and 1784 respectively. In 1782 also he produced a one-act prose comedy, Le Bon Ménage, and in the next year Galatea, a romantic tale in imitation of the Galatea of Cervantes. Other short tales and comedies followed, and in 1786 appeared Numa Pompilius, an undisguised imitation of Fénelon's Télémaque. In 1788 he became a member of the French Academy, and published Estelle, a pastoral of the same class as Galatea. Another romance, Gonsalve de Cordoue, preceded by an historical notice of the Moors, appeared in 1791, and his famous collection of Fables in 1792. Among his posthumous works are La Jeu Messe des Floraie, ou Mémoires d'un jeune Espagnol (1807), and an abridgment (1799) of Don Quixote, which, though far from being a correct representation of the original, had great and merited success.

Florian imitated Salomon Gessner, the Swiss idyllist, and his style has all the artificial delicacy and sentimentality of the Gessnerian school. Perhaps the nearest example of the class in English literature is afforded by John Wilson's (Christopher North's) Idylls of the King, L'histoire de Nostre Dame, a Romanche (1831); Another of his fables are reckoned "The Monkey showing the Magic Lantern," "The Blind Man and the Paralytic," and "The Monkeys and the Leopard."

The best edition of Florian's Oeuvres complètes appeared in Paris in 16 volumes, 1820; his Oeuvres inédites in 4 volumes, 1824. See "Vie de Florian," by L. F. Jauffret, prefixed to his Œuvres posthumes (1802); A. J. N. de Roos, Vie de Florian (Paris, An V.); Sainte-Beuve, Citataires du lundi, t. iii.; A. de Montvaillant, Florian, sa vie, ses œuvres (1879); and Lettres de Florian à Mme de la Briche, published, with a note by the baron de Barante, in Milanges (1893) by the Société des bibliophiles français.

FLORIANOS (formerly Desterro, Nossa Senhora do Desterro and Santa Catharina, and still popularly known under the last designation), a city and port of Brazil and the capital of the state of Santa Catharina, on the western or inside shore of a large island of the same name, 485 m. S.S.W. of Rio de Janeiro, in 27° 30' S., 48° 30' W. Pop. (1890) 11,400, including many Germans. (1902, estimate) 16,000; of the municipality, including a large rural district and several villages (1890), 36,687. The harbour is formed by the widening of the strait separating the island from the mainland, which is nearly 2 m. wide. The best portlets are those which open from the N. and S., which are defended by small forts. The island is mountainous and wooded, and completely shelters the harbour from eastern storms. The surroundings are highly picturesque and tropical in character, but the town itself is poorly built and unattractive. Its public buildings include the president's official residence, arsenal, lyceum, hospital and some old churches. The climate is warm for the latitude, but the higher elevations of the vicinity are noted for their mild climate and healthfulness. There are some German colonies farther to the coast whose products find a market, but a number of small settlements along the mainland coast add something to the trade of the town. The more inland towns are partly supplied from this point, but difficult mountain roads tend to restrict the trade greatly. There is a considerable trade in market produce with Rio de Janeiro, but the exports are incomparable. Santa Catharina was formerly one of the well-known whaling stations of the South Atlantic, and is now a secondary military and naval station.

The island of Santa Catharina was originally settled by the Spanish; Cabesa de Vaca landed here in 1542 and marched hence across country to Asuncion, Paraguay. The Spanish failed to establish a permanent colony, however, and the Portuguese took possession. The island was captured by a Spanish expedition under Viceroy Zeballos in 1777. A boundary treaty of that same year restored it to Portugal. In 1894 Santa Catharina fell into the possession of revolutionists against the government of President Floriano Peixoto. With the collapse of the revolution the city was occupied by the government forces, and its name was then changed to Florianopolis in honour of the President. The republic of the same name was established.

FLORIDA, the most southern of the United States of America, situated between 24° 36' and 31° N. lat. and 79° 48' and 87° 35' W. long. It is bounded N. by Georgia and Alabama, E. by the Atlantic Ocean, S. by the Strait of Florida, which separates it from Cuba, and by the Gulf of Mexico, and W. by Alabama and the Gulf. The Florida Keys, a chain of islands extending in a general south-westery direction from Biscayne Bay, are included in the state boundaries, and the city of Key West, on an island of the same name, is the seat of justice of Monroe county. The total area of the state is 38,666 sq. m., of which 3,805 sq. m. are water surface. The coast line is greater than that of any other state, extending 472 m. on the Atlantic and 674 m. on the Gulf Coast.

The peculiar outline of Florida gives it the name of "Peninsula State." The average elevation of the surface of the state above the sea-level is less than that of any other state except Louisiana, but there is not the monotony of unbroken level which descriptions and maps often suggest. The N.W. portion of the state is, topographically, similar to south-eastern Alabama, being a rolling, hilly country; the eastern section is a part of the Atlantic coastal plain; the mean coastline is less regular than the eastern, being indented by a number of bays and harbours, the largest of which are Charlotte Harbour, Tampa Bay and Pensacola Bay. Along much of the western coast and along nearly the whole of the eastern coast extends a line of sand reefs and narrow islands, enclosing shallow and narrow bodies of water, such as Indian river and Lake Worth—called rivers, lakes, lagoons, bays and harbours. In the central part of the state there is a ridge, extending N. and S. and forming a divide, separating the eastern and western coast counties. The highest elevation above sea-level is about 300 ft. The central region is remarkable for its large number of lakes, approximately 30,000 between Gainesville in Alachua county, and Lake Okeechobee. They are due largely to sinkholes or depressions caused by solution of the limestone of the region. Many of the lakes are connected by subterranean channels, and a change in the surface of one lake is often accompanied by a change in the surface of another. By far the largest of these lakes, nearly all of them shallow, is Lake Okeechobee, a body of water about 1,250 sq. m. in area and about 5 ft. deep, with a maximum depth of greater than 5 ft. Caloosathatchee river, flowing into the Gulf of Mexico near Charlotte Harbour, is its principal outlet. Among the other lakes are Orange, Crescent, George, Weir, Harris, Euclid, Apopka, Tohopperalga, Kissimmee and Istokpoga. The chief feature of the southern portion of the state is the Everglades (q.v.), the term "Everglade State" being popularly applied to Florida. Within the state there are many swamps, the largest of which are the Big Cypress Swamp in the S. adjoining the Everglades on the W., and Okeechobee Swamp, extending from Georgia into the N.E. part of the state. The chief feature of the drainage of the state is the large number of subterranean streams and of springs, always found to a greater or less extent in limestone regions. Some of them are of great size. Silver Spring and Blue Spring in Marion county, and Sanibel Spring in Orange City, are the most noted. Some of these springs are drained by the Kissimmee and its tributaries, one of them, the Green Cove Spring in Clay county, discharging about 3,000 gallons of sulphurated water per minute. Not far from St Augustine a spring bursts through the sand with such force that the ocean breakers roll back from it as from a sunken reef. The springs often merge into lakes, and lake systems are usually the sources of the rivers, Lake George being the principal one, and the St Johns and the Kissimmee, of which a number of smaller lakes are the source of the Ocklawaha, one of the most beautiful of the Floridian rivers.
Of the rivers the most important are the St. Johns, which flows N. from about the middle of the peninsula, empties into the Atlantic a short distance below Jacksonville, and is navigable for about 250 m. from its mouth to Withlacoochee, flowing in a general north-westly direction from its sources in the N.W. part of Polk county, and forming near its entrance into the Gulf of Mexico the boundary between Levy and Citrus counties, and four rivers, the Escambia, the Choctawatchee, the Apalachicola, and the Suwanee, having their sources in other states and traversing the north-western part of Florida. On account of its sand reefs, the east coast has not so many harbours as the west coast. The most important harbours are at Fernandina, St Augustine, and Miami on the E. coast, and at Tampa, Key West and Pensacola on the W. coast.

The F. has seven large rivers, prominent among them the peculiar species are the red bay or "Florida Mahogany," the juniper, and cypress, the latter being the chief forest of Florida, and cypress jelly is an important Florida product. The forests are green almost extinct. The lumber industry is important: in 1905 the total factory product of lumber and timber was valued at $10,901,650, and lumber and planing mill products valued at $3,917,458. In 1899 this was the most valuable industry in the state; in 1905 it was second to the manufacture of tobacco.

Climatic conditions are similar to those that of the southern United States. The climate is subtropical, the annual variation is small, and the temperature is very uniform, except in the far north, and the climate is much too warm for crocodile, but the number of these has been greatly diminished by hunting. Ducks, wild turkeys, bears and wild cats (lynx) are found, but in decreasing numbers.

The fisheries are very valuable; the total number of species of fish in Florida waters is about 600, and many species found on one coast are not found on the other. The king and tarpon are the sport, while mullet, shad, redfish, pompano, trout, sheephead and Spanish mackerel are of great economic value. The sponge and oyster fisheries are also important. The total product of the fisheries in 1902 was valued at about $2,000,000.

Industry and Commerce.—The principal occupation is agriculture, in which 44% of the labouring population was engaged in 1900, but only 12-6% of the total land surface was enclosed in farms, of which only 34-6% was improved, and the total agricultural product for 1899 was valued at $18,309,104.

As regards climate Florida may be divided into three more or less distinct zones. North and west of a line passing through Cedar Keys and Fernandina the climate is distinctly "southern," similar to that of the Gulf states; from this line to another extending from the mouth of the Caloosahatchee to Indian river inlet the climate is semi-tropical, but is well suited to the cultivation of pineapples. Of this the climate is sub-tropical, well adapted to the cultivation of pineapples. Since the semi-tropical and sub-tropical zones are nearer the course of the Gulf Stream, and are swept by the trade winds, their temperatures are more uniform than those of the zones of southern climate; indeed, the extremes of heat (104°F) and cold (15°F) are felt in the region of southern climate. The mean annual temperature of the state is 70-8°F., greater in the sub-tropical than in the other climate zones, and the Atlantic coast is in general warmer than the Gulf coast. The rainfall averages 52-09 in. per annum. On account of its warm climate, Florida has many resorts for health and pleasure, which are especially popular in the season from January to April; the more important are St Augustine, Ormond, Daytona, Palm Beach, Miami, Tampa, White Springs, Hampton Springs, Worthington Springs and Orange Springs.

No metals have ever been discovered in Florida. The principal minerals are rock phosphate and (except the flint rock) river pebble phosphatc. Florida is a rich source of phosphate rock in the United States for fuller's earth, a deposit of which, near Quincy, was discovered in 1893; and clay (including kaolin) is also mined to some extent. Other minerals that have been discovered but have not yet been industrially developed are coal, the barium phosphate rock, the spar, pyrites, and gold. There is a lack of a good thorough geological survey has perhaps prevented the discovery of other minerals—certainly it is responsible for a late recognition of the economic possibilities of its mineral resources.

The flora of N. Florida is similar to that of south-eastern North America; that of S. Florida seems to be a link between the vegetation of North America and that of South America. Florida is about 250 square miles larger than the island of Cuba. The flora of N. Florida has been examined, 187 are common to the West Indies, Mexico and South America. The majority of species are found in the southern part of the state, including about half of the peninsula, yellow pine being found in the coastal marsh lands, where cypress is found throughout the state, particularly abounds. Half of the forests in the United States are found, and among the peculiar species are the red bay or "Florida Mahogany," the juniper, and cypress, the latter being the chief forest of Florida, and cypress jelly is an important Florida product. The forests are green almost extinct. The lumber industry is important: in 1905 the total factory product of lumber and timber was valued at $10,901,650, and lumber and planing mill products valued at $3,917,458. In 1899 this was the most valuable industry in the state; in 1905 it was second to the manufacture of tobacco.

Climatic conditions are similar to those that of the southern United States. The climate is subtropical, the annual variation is small, and the temperature is very uniform, except in the far north, and the climate is much too warm for crocodile, but the number of these has been greatly diminished by hunting. Ducks, wild turkeys, bears and wild cats (lynx) are found, but in decreasing numbers.

The fisheries are very valuable; the total number of species of fish in Florida waters is about 600, and many species found on one coast are not found on the other. The king and tarpon are the sport, while mullet, shad, redfish, pompano, trout, sheephead and Spanish mackerel are of great economic value. The sponge and oyster fisheries are also important. The total product of the fisheries in 1902 was valued at about $2,000,000.

Industry and Commerce.—The principal occupation is agriculture, in which 44% of the labouring population was engaged in 1900, but only 12-6% of the total land surface was enclosed in farms, of which only 34-6% was improved, and the total agricultural product for 1899 was valued at $18,309,104. As the number of farms increased faster than the cultivated area from 1850 to 1900, the average size of farms declined from 444 acres in 1860 to 140 in 1880 and to 106-9 in 1900, the largest class of farms being those with an acreage varying from 20 to 50 acres. Nearly three-fourths of the farms, in 1900, were cultivated by their owners, but the cash tenantry system showed an increase of 100% since 1890, being most extensively used in the cotton counties. One-third of the farms were operated by negroes, but one-half of these were rented, and the value of negro farm property was only one-eighth that of the entire farmland property of the state. According to the state census of 1905 only 1,521,362 acres were improved; of 45,984 farms, 31,233 were worked by whites.

Fruits normally form the principal crop; the total value for 1907-8 of the fruit crops of the state (including oranges, lemons, limes, grape-fuit, bananas, guavas, pears, peaches, grapes, figs, pecans, &c.) was $6,160,299, according to the report of the State Department of Agriculture. The discovery of Florida's adaptability to the cultivation of oranges about 1875 may be taken as the beginning of the state's modern industrial development. But the unusual severity of the winters of 1887, 1894 and 1899 (the report of the Twelfth Census which gives the figures for this year being therefore misleading) destroyed three-fourths of the orange trees, and caused an increased attention to stock-raising, and to various agricultural products. Orange culture has recovered much of its importance, but it is carried on in the more southern counties, the state planters of pinellia, in sub-tropical Florida, is proving successful, the total production far surpassing that of California, the only other state in the Union in which pineapples are grown. Grape-fuit, guavas and lemons are also successfully produced in this part of the state.

The cultivation of strawberries and vegetables (cabbage, cauliflower, beets, beans, tomatoes, egg plant, cucumbers, water-melons, celery, &c.) for northern markets, and of orchard fruits, especially plums, pears and prunes, has likewise proved successful. In 1907, according to the State Department of Agriculture, the total value of vegetable crops was $1,621,362, and the value of the various agricultural products was $3,928,675. In 1903, according to the statistics of the United States Department of Agriculture, Indian corn ranked next to fruits (as given in the state reports), but its product as compared with that of various other states is unimportant— in 1907 it amounted to 7,017,000 bushels only; rice is the only other cereal whose yield in 1899 was greater than that of 1886, but the Florida product was surpassed (in 1899) by that of the Carolinas, Georgia, Louisiana and Texas; in 1907 the product of rice in Florida (603,000 bushels) was less than that of Texas, Louisiana, South Carolina, Arkansas and Georgia severally. Tobacco culture, which declined after 1860 on account of the competition of Cuba and Sumatra, has revived since 1885 through the introduction of Cuban and Sumatran seed; the product of 1907 (6,937,500 lb) was more than six times that of
FLORIDA

1899, the product in 1899 (1,125,600 lb) being more than twice that of 1889 (476,443 lb), which in turn was more than twenty times that of 1880 (21,182 lb)—the smallest production recorded for many decades. In 1907 the average for the state was 550,000 lb. Tobacco growing was highly concentrated in a few counties, and in any other state. In 1898, 84% of the product was raised in Gadsden county. The sweet potato and pea-nut crops have also become very valuable; on the other hand the Census of 1900 showed a decline in acreage and production of cotton. In 1907 the acreage (265,000 acres) was less than in any cotton-growing state except Missouri and Virginia; the crop for 1907–1908 was 49,794 bales. Sea-island cotton of very high grade is grown in Alachua county. The production of sugar, begun by the early Spanish settlers, declined, but that of syrup increased. Florida's three most important products are tobacco, sugar, and lumber.

Irrigation, introduced in 1888 by the orange growers, has been adopted by other farmers, especially the tobacco-growers of Gadsden county, and so the evil effects of the droughts, so common from February to June, are avoided. The value of farm property in the southern counties, which have been developed very recently, shows a steady increase, that of Hillsboro county surpassing that of any of the others. In 1900, the total value of all field crops (cotton, cereals, sugar-cane, hay and forage, sweet potatoes, &c.) was $11,856,340, and the total value of all farm products (including live stock, $30,817,804, poultry and products, $1,688,433, and dairy products, $1,728,642) was $45,671,320.

The manufactures of Florida, as compared with those of other states, are unimportant. Their product in 1900 was more than twice that of the state in 1890, and the production in 1905 (from establishing the tobacco factory system only) was $50,298,280, i.e., 47% greater than in 1900. The most important industries were those that depended upon the forests, their product amounting to nearly 45% of the total. The lumber, turpentine, and timber products were valued in 1905 at $10,001,650, almost twice their valuation in 1890, and an increase of 12% over the product of 1900. The manufacture of turpentine and resin, material for which is obtained from the pine forests, had increased greatly in importance between 1890 and 1900, the product in 1890 being valued at only $191,859, that of 1900 at $8,499,505, and from the latter sum it increased in 1905 to $9,401,965, an increase of more than one-half. In 1900 the state ranked second and in 1905 first of all the states of the country in the value of this product; in 1905 the state's product amounted to 54% of that of the entire country. The manufacture of cigars and cigarettes (almost entirely made from a few cigarettes being manufactured), carried on chiefly by Cubans at Key West and Tampa, also increased in importance between 1890 and 1900. Products valued in 1890 at $11,973,826, or more than one-quarter more than in 1890, and in 1905 there was a further increase of 56 2/3%, the gross value being $16,764,276, or nearly one-third of the total factory product of the state. In 1900 Florida ranked fourth in the manufacture of tobacco among the states of the Union, being surpassed by New York, Pennsylvania and Ohio; in 1905 it ranked third (after New York and Pennsylvania). Most of the tobacco used is imported from Cuba, though, as has been indicated, the production of the state has greatly increased since 1880. In the manufacture of fertilizers, the raw material for which is derived from the phosphate beds, Florida's aggregate product in 1900 was valued at $900,329, and in 1905 at $1,590,371, an increase of 217 9/7% in five years.

Florida's industrial progress has been mainly since the Civil War, for before that conflict a large part of the state was practically undeveloped. An important influence has been the railways. In 1880 the total railway mileage was 518 m.; in 1890 it was 2,480 m.; in 1900, 3,255 m., and in January 1909, 4,009 92 m. The largest system is the Atlantic Coast Line, the lines of which in Florida were built or consolidated by H. B. Plant (1819–1899) and succeeding him the so-called "Plant System" of railways. The Florida East Coast Railway is also the product of one man's faith in the country, that of Henry M. Flagler (b. 1838). The Seaboard Air Line, the Louisville & Nashville, and the Georgia Southern & Florida are the other important railways. The Southern railway penetrates the state as far as Jacksonville, over the tracks of the Atlantic Coast Line. A state railway commission, whose members are elected by the people, has power to enforce its schedule of freight rates except when such rates would not pay the operating expenses of the railway. In 1882 the Florida East Coast Line Canal and Transportation Co. was organized to develop a waterway from Jacksonville to Biscayne Bay by connecting with canals at St. Johns, Matanzas, and Halifax rivers, Mosquito Lagoon, Indian river, Lake Worth, Hillsboro river, New river, and Snake Creek; in 1908 this vast undertaking was completed. The development of marine commerce has been retarded by unimproved harbours, but Fernandina and Pensacola harbours have always been good. Since 1890 much has been done by the national Government, aided in many cases by the local authorities and by private enterprise, to improve the harbours and to extend the limits of river navigation. With the increase of trade between the United States and the West Indies following the Spanish-American War (1898), the business of the principal ports, notably of Fernandina, Tampa and Pensacola, greatly increased.

Population.—The population of Florida in 1880 was 260,493; in 1890, 391,422, an increase of 45.2%; and in 1900, 528,542, or a further increase of 35.2%; and in 1905, by a state census, 614,835; and in 1910, 752,619. In 1900, 95.7% were native-born, 43.7% were coloured (including 479 Chinese, Japanese and Indians), and in 1905 the percentages were little altered. The Seminole Indians, whose number is not definitely known, live in the Everglades. The urban population was on the basis of places having a population of 400 or more was 16.6% of the total in 1900 and 22.7% in 1905, the percentage for Florida, as for other Southern States, being small as compared with the percentage for most of the other states of the Union. In 1900 there were 92, and in 1905, 125 incorporated cities, towns and villages; but only 14 (in 1905, 22) of these had a population of over 2000, and only 4 (in 1905, 8) a population of more than 5000. The four in 1905 were: Jacksonville (28,420); Pensacola (17,747); Key West (17,114); and Tampa (15,839). The eight in 1905 were Jacksonville (33,501), Tampa (22,853), Pensacola (21,726), Key West (8,248), Live Oak (5,366), Gainesville (5,193), and St Augustine (3,121). Tallahassee is the capital of the state. In 1890 the Baptists were the strongest religious denomination; the Methodists ranked second, while the Roman Catholic, Presbyterian and Protestant Episcopal churches were of relatively minor importance.

Government.—The present constitution was framed in 1885 and was ratified by the people in 1886. Its most important feature, when compared with the previous constitution of 1868, is its provision for the choice of state officials other than the governor by popular vote, and the governor's term of office instead of by the governor's appointment, but the governor, who serves for four years and is not eligible for the next succeeding term, still appoints the circuit judges, the state attorneys for each judicial circuit and the county commissioners; he may fill certain vacancies and may suspend, and with the Senate remove officers not liable to impeachment. The governor is a member of the Board of Pardons, the other members being the attorney-general, the secretary of state, the comptroller and the commissioner of agriculture; he and the secretary of state, attorney-general, comptroller, treasurer, superintendent of public instruction, and commissioner of agriculture comprise a Board of Commissioners of State Institutions; he is also a member of the Board of Education. The office of lieutenant-governor was abolished by the present constitution. The legislature meets biennially, the senators being chosen for four, the representatives for two years. By an amendment of 1896 the Senate consists of not more than 32, and the House of Representatives of not more than 68 members; by a two-thirds vote of members present the legislature may pass, still the governor's assent, an ordinary law; but the circuit court shall serve for six years, those of the county courts for four years, and justices of the peace (one for each justice district, of which the county commissioners must form at least two in each county) hold office for four years. The constitutional qualifications for suffrage are: the age of twenty-one years, citizenship in the United States or presentation of naturalization
certificates at registration centres, residence in the state one year and in the county six months, and registration. To these requirements the payment of a poll-tax has been added by legislative enactment, such an enactment having been authorized by the constitution. Insane persons and persons under guardianship are excluded by the constitution, and "all persons convicted of bribery, perjury, larceny, embezzlement, forgery, and other crimes who shall make or become directly or indirectly interested in any bet or wager the result of which shall depend upon any election," or who shall participate as principal, secondary or challenger in any duel, are excluded by legislative enactment.

Amendments to the constitution may be made by a three-fifths vote of each house of the legislature, ratified by a majority vote of the people. A revision of the Constitution may be made upon a two-thirds vote of all members of both Houses of the legislature, if ratified by a majority vote of the people; a Constitutional Convention is then to be provided for by the legislature, such convention to meet within six months of the passage of the law therefor, and to consist of a number equal to the membership of the House of Representatives, apportioned among the counties, as are the members of this House.

A homestead of 160 acres, or of one-half of an acre in an incorporated town or city, owned by the head of a family residing in the state, with personal property to the value of $1000 and the improvements on the real estate, is exempt from enforced sale except for delinquent taxes, purchase money, mortgage or judgment liens held on the property. The wife holds in her own name property acquired before or after marriage; the intermarriage of whites and negroes (or persons of negro descent to the fourth generation) is prohibited. All these are constitutional provisions. By legislative enactment whites and blacks living in adultery are to be punished by imprisonment or fine; divorces may be secured only after two years' residence in the state and on the ground of physical incapacity, adultery, extreme cruelty, habitual indulge in violent temper, habitual drunkenness, desertion for one year, previous marriage still existing, or such relationship of the parties as is within the degrees for which marriage is prohibited by law. Legitimacy of natural children can be established by subsequent marriage of the parents, and the age of consent is sixteen years.

The bonded debt was incurred during the Reconstruction Period (1865-1875). In 1871 7% 30 year bonds to the extent of $550,000 were issued and in 1873 another issue of 6½% 30 year bonds to the value of $700,000. Most of these were held by the Educational Fund at the time of their maturity. By 1901 all but $267,700 of the issue of 1871 had been retired and this amount was refunded with 2½% 30 year bonds which were taken by the Educational Fund. In 1903 $416,800 of the 1873 issue was held by the Educational Fund and $148,000 by individuals. The first part of this claim was refunded by a general appropriation, and the second was paid from an Indian war claim of $922,466, received from the United States government in 1902, when $1,020,000 bonds of 1857, held by the United States government, were also refunded, the bonded debt thus was reduced to $884,500; and on the 1st of January 1909 the debt, consisting of refunding bonds held as educational funds, amounted to $601,507.

Penal System.—There is no penitentiary; the convicts are hired to the one highest bidder who contracts for their labour, and moreover, to lease all other persons convicted during the term of the lease, and sub-leases the prisoners. In 1889 the convicts were placed under the care of a supervisor of convicts, and in 1905 the law was amended so that one or more supervisors could be appointed at the will of the governors. In 1908 there were four supervisors and one state prison physician, and there are special laws designed to prevent abuses in the system. In 1908 the state released 7 convicts, the least lease, the $208,148 from the lease of convicts being first released, but in 1906 the lease excluded such as were thought unfit by the state prison physician. Women convicts were still leased with the men in 1908; of the 446 convicts committed in that year, there were 15 negro females, 336 negro males and 75 white males. In the same year 54 escaped, and 27 were recaptured. The leased convicts are employed in the turpentine and lumber industries and in the phosphate works.

The 1723 convicts "on hand" at the close of 1908 were held in 38 camps, 4 being the minimum, and 160 the maximum number, at a camp. In 1908 two central hospitals for the convicts were maintained by the lessee company. County prison camps are under the supervision of the governor and the supervisors of convicts. The state supervisors must inspect each state prison camp and each county prison camp once every other year, or who shall participate as principal, secondary or challenger in any duel, are excluded by legislative enactment.

Education.—As early as 1831 an unsuccessful attempt was made to form an adequate public school fund; the first real effort to establish a common school system for the territory was made after 1835; in 1840 there were altogether 18 academies and 51 common schools, and in 1849 the state legislature made an appropriation in the interest of the public instruction of white pupils, and this was supplemented by the proceeds of land granted by the United States government for the same purpose. In 1852 Tallahassee established a public school; and in 1860 there were, according to a report of the United States census, 2032 pupils in the public schools of the state, and 44 at "academies and other schools." The Civil War, however, interrupted the early progress, and the present system of common schools dates from the constitution of 1868 and the school law of 1869. The school revenue derived from the interest of a permanent school fund, special state and county taxes, and a poll-tax, in 1907-1908 amounted to $1,716,191; the per capita cost for each child of school age was $61.11 (white, $6.08; negro, $2.14), and the average school term was 198 days (112 for white, 90 for negroes). The state constitution prescribes that "white and colored children shall not be taught in the same school, but impartial provision shall be made for both." The percentage of enrolment in 1907-1908 was 60 (whites, 66; negroes, 52). The percentage of attendance to enrolment was 70%—68% for white and 74% for negro schools. Before 1905 the state provided for higher education by the Florida State College, at Tallahassee, formerly the West Florida Seminary (founded in 1857), the University of Florida, at Gainesville, and the Florida Agricultural College (founded in 1883) at Fayetteville, and by an act of 1903 by enlarging the work of the Florida Agricultural College (founded in 1884); the East Florida Seminary, at Gainesville (founded 1848 at Ocala); the normal school (for whites) at De Funiak Springs; and the South Florida Military Institute at Bartow; but in 1905 the legislature passed the Buckman bill abolishing all these state institutions for higher education and establishing in their place the university of the state of Florida and a state Agricultural Experiment Station, both now at Gainesville, and the Florida Agricultural College at Fayetteville for farmers for entrance and for graduation as the state university for men. Private educational institutions in Florida are John B. Stetson University at De Land (Baptist); Rollins College (1885) at Winter Park (non-sectarian), with a collegiate department, an academy, a school of music, a school of expression, a school of fine arts, a school of domestic and industrial arts, and a business school; Southern College (1901), at Sutherland (Methodist Episcopal, South); the Presbyterian College of Florida (1905), at Eustis; Jasper Normal Institute, at Jasper, and the Florida Normal Institute at Madison.

The negroes have facilities for advanced instruction in the Florida Baptist Academy, and Cookman Institute (Methodist Episcopal, South), both at Jacksonville, and in the Normal and Manual Training School (Congregational), at Orange Park. There are a school for the Blind, Deaf, and Dumb (1883) at St. Augustine, a hospital for the insane at Chattahoochee and a reform school at Marianna, all wholly supported by the state, and a Confederate soldiers' and sailors' home at Tallahassee, which is partially supported by the state.

History.—The earliest explorations and attempts at colonization of Florida by Europeans were made by the Spanish. The Council of the Indies claimed that since 1510 fleets and ships had gone to Florida, and Florida is shown on the Cantino map of 1502. In 1513 Juan Ponce de Leon (c. 1460-1521), who had been with Christopher Columbus on his second voyage and had later been governor of Porto Rico, obtained a royal grant authorizing him to discover and settle "Bimini," a fabulous island believed to contain a marvellous fountain or spring.
whose waters would restore to old men their youth or at least had wonderful curative powers. Soon after Easter Day he came in sight of the coast of Florida, probably near the mouth of the St Johns river. From the name of the day in the calendar, Pascua Florida, or from the fact that many flowers were found on the coast, the country was named Florida. De Leon seems to have explored the coast, to some degree, on both sides of the peninsula, and to have turned homeward fully convinced that he had discovered an immensely large island. He returned to Spain in 1514, and obtained from the king a grant to colonize "the island of Bimini and the island of Florida," of which he was appointed adelantado, and in 1521 he made another expedition, this one for colonization as well as for discovery. He seems to have touched at the island of Tortugas, so named on account of the large number of turtles found there, and to have landed at several places, but many of his men succumbed to disease and he himself was wounded in an Indian attack, dying soon afterward in Cuba. Meanwhile, in 1516, another Spaniard, Diego Miruelo, seems to have sailed for some distance along the west coast of the peninsula. The next important exploration of Florida was that of Panfilo de Narvaez. In 1527 he sailed from Cuba with about 600 men (soon reduced to less than 400), landed (early in 1528) probably at the present site of Pensacola, and for six months remained in the country, he and his men suffering terribly from exposure, hunger and fierce Indian attacks. In September, his ships being lost and his force greatly reduced in number, he hastily constructed a crafty fleet, reembarked probably at Apalachee Bay, and lost his life in a storm probably near Pensacola Bay. Only four of his men, including Nuñez Cabeza de Vaca, succeeded after eight years of Indian captivity and of long and weary wanderings, in finding their way to Spanish settlements in Mexico. Florida was also partially explored by Ferdinando de Soto (q.v.) in 1539-1540. In the summer of 1559 another attempt at colonization was made by Tristan de Luna, who sailed from Vera Cruz, landed at Pensacola Bay, and explored a part of Florida and (possibly) Southern Alabama. Somewhere in that region he desired to make a permanent settlement, but he was abandoned by most of his followers and gave up his attempt in 1561.

In the following year, Jean Ribaut (1520-1556), with a band of French Huguenots, landed first near St Augustine and then at the mouth of the St Johns river, which he called the river of May, and on behalf of France claimed the country, which he described as "the fairest, fruitfullest and pleasantest of all the world"; but he made his settlement on an island near what is now Beaufort, South Carolina. In 1564 René de Laudonnière (?) -c. 1586), with another party of Huguenots, established Fort Caroline probably at the mouth of St Johns Bay, and lost his life in a storm not prosper, and in 1565 Laudonnière was about to return to France when (on the 28th of August) he was reinforced by Ribaut and about 300 men from France. On the same day that Ribaut landed, a Spanish expedition arrived in the bay of St Augustine. It was commanded by Pedro Menéndez de Avilés (1523-1574), one of whose aims was to destroy the Huguenot settlement. This he did, putting to death almost the entire garrison at Fort Caroline "not as Frenchmen, but as Lutherans," on the 20th of September 1565. The ships of Ribaut were soon after wrecked near Matanzas Inlet; he and most of his followers were captured, and Menéndez and they were executed. Menéndez then turned his attention to the founding of a settlement which he named St Augustine (q.e.t.; he also explored the Atlantic coast from Cape Florida to St Helena, and established forts at San Mateo (Fort Caroline), Avista, Guale and St Helena. In 1567 he returned to Spain in the interest of his colony.

The news of the destruction of Fort Caroline, and the execution of Ribaut and his followers, was received with indifference at the French court; but Dominique de Gourgues (c. 1530-1593), a friend of Ribaut but probably a Catholic, organized an expedition of vengeance, not informing his men of his destination until three of their ships were near the Florida coast. With the co-operation of the Indians under their chief Saturiba he captured Fort San Mateo in the spring of 1568, and on the spot where the garrison of Fort Caroline had been executed, he hanged his Spanish prisoners, inscribing on a tablet of pine the words, "I do this not as unto Spaniards but as to traitors, robbers and murderers." Feeling unable to attack St Augustine, de Gourgues returned to France.

The Spanish settlements experienced many vicissitudes. The Indians were hostile and the missionary efforts among them failed. In 1568 St Augustine was almost destroyed by Sir Francis Drake and it also suffered severely by an attack of Captain John Davis in 1565. No until the last decade of the 17th century did the Spanish authorities attempt to extend the settlements beyond the east coast. Then, jealous of the French explorations along the Gulf of Mexico, they turned their attention to the west coast, and in 1696 founded Pensacola. When the English colonies of the Carolinas and Georgia were founded, there was constant friction with Florida. The Spanish were accused of inciting the Indians to make depredations on the English settlements and of interfering with English commerce and the Spanish were in constant fear of the encroachments of the British. In 1702, when Great Britain and Spain were contending in Europe, on opposite sides, in the war of the Spanish Succession, a force from South Carolina captured St Augustine and laid siege to the fort, but being unable to reduce it for lack of necessary artillery, burned the town and withdrew at the approach of Spanish reinforcements. In 1706 a Spanish and French expedition against Charleston, South Carolina, failed, and the Carolinians retaliated by invading middle Florida in 1708. In 1722 Governor Oglethorpe, governor of Georgia, supported by a naval force, made an unsuccessful attack upon St Augustine; two years later a Spanish expedition against Savannah by way of St Simon's Island failed, and in 1745 Oglethorpe again appeared before the walls of St Augustine, but the treaty of Aix-la-Chapelle in 1748 prevented further hostilities. Pensacola, the other centre of Spanish settlement, though captured and occupied (1719-1723) by the French from Louisiana, had a more peaceful history.

By the treaty of Paris in 1763 Florida was ceded to England in return for Havana. The provinces of East Florida and West Florida were now formed, the boundaries of West Florida being 31° N. lat. (when civil government was organized in 1767, the N. line was made 32° 28'), the Chattoochee, and the Apalachicola rivers, the Gulf of Mexico, Mississippi Sound, Lakes Borgne, Ponchatrain and Maurepas, and the Mississippi river. A period of prosperity now set in. Civil in place of military government was instituted; immigration began; and Andrew Turnbull, an Englishman, brought over a band of about 1,500 Minorcas (1767), in whom he engaged in the cultivation of indigo at New Smyrna. Roads were laid out, some of which yet remain; and in the last three years of English occupation the government spent $580,000 on the two provinces. Consequently, the people of Florida were for the most part loyal to Great Britain during the War of American Independence. In 1776, the Minorcas of New Smyrna refused to work longer on the indigo plantations; and many of them removed to St Augustine, where they were protected by the authorities. Several plans were made to invade South Carolina and Georgia, but none materialized until 1780, when an expedition was organized which co-operated with British forces from New York in the siege of Savannah, Georgia. In the following year, Spain having declared war against Great Britain, Don Bernardo de Galvez (1756-1794), the Spanish governor at New Orleans, seized most of the English forts in West Florida, and in 1781 captured Pensacola.

By the treaty of Paris (1783) Florida reverted to Spain, and, no religious liberty being promised, many of the English inhabitants left East and West Florida. A dispute with the United States concerning the northern boundary was settled by the treaty of 1795, the line 31° N. lat. being established. The westward expansion of the United States made necessary American ports on the Gulf of Mexico; consequently the acquisition of West Florida as well as of New Orleans was one of the
aims of the negotiations which resulted in the Louisiana Purchase of 1803. After the cession of Louisiana to the United States, the people of West Florida feared that that province would be seized by Bonaparte, and therefore, through a convention at Bouhler’s Plains (July 17, 1812), they appealed to Congress for more effective government. When it was found that the Spanish governor did not accept these plans in good faith, another convention was held on the 26th of September which declared West Florida to be an independent state, organized a government and petitioned for admission to the American Union. On the 27th of October President James Madison, acting on a theory of Robert R. Livingston that West Florida was ceded by Spain to France in 1800 along with Louisiana, and was therefore included in the Louisiana Purchase, asked Congress to appropriate funds for the occupation of the country in order that it might not be seized by Great Britain and made a base of military operations. When the request was refused, American forces seized Fernandina in the spring of 1812, an action that was repudiated by the American government after protest from Spain, although it was authorized in official instructions. About the same time an attempt to organize a government at St. Mary’s was made by American sympathizers, and a petty civil war began between the Americans, who called themselves "Patriots," and the Indians, who were encouraged by the Spanish. In 1814 British troops landed at Pensacola to begin the operations against the United States, which continued long after peace was concluded in 1814. In 1818 General Jackson, believing that the Spanish were aiding the Seminole Indians and inciting them to attack the Americans, again captured Pensacola. By the treaty of 1819 Spain formally ceded East and West Florida to the United States, and the treaty was ratified in 1821, when the United States took formal possession, but civil government was not established until 1822.

Indian affairs furnished the most serious problems of the new Territory of Florida. The aborigines, who seemed to have reached a stage of civilization somewhat similar to that of the Aztecs, were conquered and exterminated or absorbed by Creeks about the middle of the 18th century. There was a strong demand for the removal of these Creek Indians, known as Seminoles, and by treaties at Payne’s Landing in 1821 and Fort Gibson in 1833 the Indian chiefs agreed to exchange their Florida lands for equal territory in the western part of the United States. But a strong sentiment against removal suddenly developed, and the efforts of the United States to enforce the treaty brought on the Seminole War (1836–42), which resulted in the removal of all but a few hundred Seminoles whose descendants still live in southern Florida.

In 1845 Florida became a state of the American Union. On the 10th of January 1861 an ordinance of secession, which declared Florida to be a "sovereign and independent nation," was adopted by a state convention, and Florida became one of the Confederate States of America. The important coast towns were rapidly captured by Union forces; Fernandina, Pensacola and St. Augustine in 1862, and Jacksonville in 1863; but an invasion of the interior in 1864 failed, the Union forces being repulsed in a battle at Olustee (on the 20th of February 1864).

In 1865 a provisional government was appointed by President Andrew Johnson, and a new state government was organized. The legislature of 1866 rejected the Fourteenth Amendment to the Federal Constitution, and soon afterwards Florida was made a part of the Third Military District, according to the Reconstruction Act of 1867. Negroes were now registered as voters by the military authorities, and another Constitutional Convention met in January and February 1868. A factional strife in the dominant party, the Republican, now began; fifteen delegates withdrew from the convention; the others framed a constitution, and then resolved themselves into a political convention. The seceding members with nine others then returned and organized; but the factions were reconciled by General George M. Meade. A new constitution was framed and was ratified by the electors, and Florida passed from under a quasi-military to a full civil government on the 4th of July 1868.

The factional strife in the Republican party continued, a number of efforts being made to impeach Governor Harrison Reed (1813–1819). The decisive year of the Reconstruction Period was 1876. The canvassing board, which published the election returns, cast out some votes, did not wait for the returns from Dade county, and declared the Republican ticket elected. George F. Drew (1827–1900), the Democratic candidate for governor, then secured a mandamus from the circuit court restraining the board from going behind the face of the election returns; this was not obeyed and a similar mandamus was therefore obtained by the Governor-elect in Florida, which declared that the board had no right to determine the legality of a particular vote. According to the new count thus ordered, the Democratic state ticket was elected. By a similar process the board’s decision in favour of the election of Republican presidential electors was nullified, and the Democratic electors were declared the successful candidates; but the electoral commission, appointed by Congress, reversed this decision. (See Electoral Commission.)

Since 1876 Florida has been uniformly Democratic in politics.

#### Bibliography—Physical and economic conditions are discussed in a pamphlet (591 pp.) published by the State Department of Agriculture, Florida, a Pamphlet Descriptive of its History, Topography, Climate, Soil, &c. (Tallahassee, 1903); a "History of the Natural Resources of Florida" (United States Department of Agriculture, Washington, 1892); A Preliminary Report on the Soils of Florida (United States Department of Agriculture, Division of Soils, Bulletin 13, 1898); C. L. Norton’s "Handbook of Florida" (2nd edition, New York, 1892), and the volumes of the Twelfth Census of the United States (for 1890) which treat of Agriculture and Manufactures, and the Special Report on the Soils and Quarries of Florida, J. N. McGonigle’s "Geography of Florida" ("National Geographic Magazine", vol. 7, T. D. A. Cockey’s "West Indian Fauna in Florida" (Nature, vol. 40), L. F. Florida’s "Florida Keys" (American Naturalist, vol. 11), and C. F. Millspaugh’s Flora of the Sand Keys of Florida (Chicago, 1907), a Field Columbian Museum publication, are of value. To sportsmen, C. B. Cory’s "Hunting and Fishing in Florida" (Boston, 1896) and A. W. and
FLORIDABLANCA—FLORIO

J. A. Dimock's *Florida Enchanted* (New York, 1908) are of interest. For administration, see Wilbur F. Yocum's *Civil Government of Florida* (New York, 1906). *The氓ited States of Florida* (New York, 1892). The standard history is that by G. R. Fairbanks, *History of Florida* (Philadelphia, 1871). This should be supplemented by B. B. Gervin's *Naissance et ...* (1899). It has an excellent descriptive bibliography of the early explorations: Woodbury Lowrey, *The Spanish Settlements within the Present Limits of the United States* (New York, 1, 1901; vol. 2, sub-title Florida, 1905); R. L. Campbell's *Historical Sketches of Colonial Florida* (Cleveland, 1892), which treats at length of the history of Pensacola; H. E. Chamber's *West Florida's Relation to the Historical Cartography of the United States* (Johns Hopkins Studies in Historical and Political Science, Series 16, No. 6); and Herbert B. Fuller's *The Purchase of Florida; its History and Character* (Cleveland, O., 1906). The only published collections of documents relating to the state are Buckingham Smith's *Collection of Various Documents for the History of Florida* (London, 1857), and Benjamin F. French's *Historical Collections of Louisiana* (New York, 1849-1875).

**FLORIDABLANCA, DON JOSE MOÑINO Y REDONDO, COUNT OF** (1748-1808), Spanish statesman, was born at Murcia in 1728. He was the son of a retired army officer, and received a good education, which he completed at the university of Salamanca, especially applying himself to the study of law. For a time he followed the profession of an advocate, and acquired a high reputation. A more public career was opened to him by the marquis of Esquilache, then chief minister of state, who sent him ambassador to Pope Clement XIV. Successful in his mission, he was then appointed by the Pope, on the death of the count, to be the pro-curial and his administration was one of the most brilliant Spain had ever seen. He regulated the police of Madrid, reformed many abuses, projected canals, established many societies of agriculture and economy and many philanthropical institutions, and gave encouragement to learning, science and the fine arts. Commerce flourished anew under his rule, and the long-standing disputes with Portugal about the South American colonies were settled. He sought to strengthen the alliance of Spain with Portugal by a double marriage between the members of the royal houses, designing by this arrangement to place ultimately a Spanish prince on the throne of Portugal. But in this he failed. Floridablanca was the right-hand man of King Charles III. in his policy of domestic reform, and was much under the influence of French *philosophes* and economic writers. Like other reformers of that school he was a strong supporter of the royal authority and a convinced partisan of benevolent despotism. The French Revolution frightened him into reaction, and he advocated the support of the first coalition against France. He retained his office for three years under Charles IV.; but in 1792, through the influence of the favourite Godoy, he was dismissed from power and exiled to Pamplona. Here he was saved from starvation only by the intervention of his brother. He was afterwards allowed to retire to his estates, and remained in seclusion till the French invasion of 1808. He was then called by his countrymen to take the presidency of the central junta. But his strength failed him, and he died at Sevilla on the 20th of November of the same year. He left several short treatises on jurisprudence. See *Obres originales del Conde de Floridablanca*, edited, with biographical introduction, by A. Ferrer del Rio; in the *Biblioteca de Riberandesa*, vol. lix.

**FLORIDOR [JOSE DE SOULAS, Sieur de Prinofosse] (d. c. 1671).** French actor, was born in Brie in the 17th century, the son of a gentleman of German family who had moved to France, married there, and become a Roman Catholic. The son entered the French army, but after being promoted ensign, quit the army for the theatre, where he took the name of Floridor. His first Paris appearance was in 1640. Three years later he was called to the company at the Hotel de Bourgogne, where he played all the leading parts in tragedy and comedy and became the head of his profession. He was a man of superb physique and excellent carriage, with a flexible and sonorous voice, and manners of rare distinction and elegance. He was much liked at court, and Louis XIV. held him in particular esteem. He died in 1671 or 1672.

**FLORIN,** the name applied to several coins of the continent of Europe and to two coins struck in England at different times. The word comes through the Fl. *florin* from the Ital. *fiorino*, flower, Lat. *flos, florere*. Fiorino was the Italian name of a gold coin issued at Florence in 1253, weighing about fifty-four grains. This coin bore on the obverse a lily, from which it took its name of "the flower", and on the reverse the Latin name of the city *Florentia*, from which it was also known as a "dorate," "Florin" and "florenc" seem to have been used in English indiscriminately as the name of this coin. The Florintine florin was held in great commercial repute throughout Europe, and similar coins were struck in Germany, other parts of Italy, France, &c. The English gold florin was introduced by Edward III. in 1343. Half and quarter florins being struck at the same time. This gold florin weighed 108 grains and was to be current for six shillings. It was found, however, to be overvalued in England on account of the silver currency and was demonetized the following year. The florin did not again appear in the English coinage until 1849, when silver coins with this name, having a nominal value of two shillings (one-tenth of a pound), were struck. When first issued the "Dei gratia" was omitted from the inscription, and they were frequently referred to as the "Godless" or "graceless" florins. The D.G. was added in 1852. In 1857 a double florin or four shilling piece was issued, but its coinage was discontinued in 1890. The total value of double florins issued during these years amounted to £533,125. (See Charles H. Smith in *Numismatic Journal*, 1889.)

**FLORIO, GIOVANNI** (1553-1629), English writer, was born in London about 1553. He was of Tuscan origin, his parents being Waldenses who had fled from persecution in the Valtelline and taken refuge in England. His father, Michael Angelo Florio, was pastor of an Italian Protestant congregation in London in 1550. He was attached to the household of Sir William Cecil, but dismissed on a charge of immorality. He dedicated a book on the Italian language to Henry Herbert, and may have been a tutor in the family of William Herbert, earl of Pembroke. Anthony A Wood says that the Florios left England on the accession of Queen Mary, but returned after her death. The son resided for a time at Oxford, and was appointed, about 1576 tutor to the son of Richard Barnes, bishop of Durham, then studying at Magdalen College. In 1578 Florio published a work entitled *Pierstre Fruits*, which yield *Familiar Speech*, *Merry Proverbs*, *Witty Sentences*, and *Golden Sayings* (4to). This was accompanied by *A Perfect Induction to the Italian and English Tongues*. The work was dedicated to the earl of Leicester. Three years later Florio was admitted a member of Magdalen College, and became a teacher of French and Italian in the university of Oxford. He died in 1629. His translation of *Boccaccio's Decameron*, or *Twelve Trees*, of divers but delightsome Tastes to the Tongues of Italian and English men; to which was annexed the *Garden of Recreation*, yielding six thousand Italian Proverbs (4to). These manuals contained an outline of the grammar, a selection of dialogues in parallel columns of Italian and English, and longer extracts from classical Italian writers in prose and verse. Florio had many patrons; he says that he "lived some years" with the earl of Southampton, and the earl of Pembroke also befriended him. His Italian and English dictionary, *Italian and English Dictionary* (1611), was reprinted as *A Dictionary of Words, already used or to be used, in both English and Italian* (1613). After the accession of James I., Florio was named French and Italian tutor to Prince Henry, and afterwards became a gentleman of the privy chamber and clerk of the closet to the queen, whom he also instructed in languages. His *magnum opus* is the admirable translation of the Essays on Moralt, Politike, and Militarie Discourses of Lo. Michaeli de Montaigne, published in folio in 1603 in three books, each dedicated to two noble ladies. A second edition in 1613 was dedicated to the queen. Special interest attaches to the first edition from the circumstance that of the several copies in the British Museum library one bears the autograph of Shakespeare—long received as genuine but now supposed to be by an 18th-century hand—and another that of Ben Jonson. It was suggested by Warburton that Florio is satirized by Shakespeare under the character of Holofernes, the
pompous pedant of Love's Labour's Lost, but it is much more likely, especially as he was one of the earl of Southampton's protégés, that he was among the personal friends of the dramatist, who may well have gained his knowledge of Italian and French from him. He had married the sister of the poet Daniel, and had friendly relations with many writers of his day. Ben Jonson sent him a copy of Volpone with the inscription, "To eldest son and worthy friend Master John Florio, Ben Jonson seals this testimony of his friendship and love." He is characterized by Wood, in Athenae Oxonienses, as a very useful man in his profession, zealous for his religion, and deeply attached to his adopted country. He died at Fulham, London, in the autumn of 1625.

FLORIS, FRANS, or more correctly Frans de Vriendt, called Floris (1520-1570), Flemish painter, was one of a large family trained to the study of art in Flanders. Son of a stone-cutter, Cornelis de Vriendt, who died at Antwerp in 1538, he began life as a student of sculpture, but afterwards gave up carving for painting. At the age of twenty he went to Liège and took lessons from Lambert Lombard, a pupil of Mabuse, whose travels in Italy had transformed a style truly Flemish into that of a mongrel Leonardsque. Following in the footsteps of Mabuse, Lambert Lombard had visited Florence, and caught the manner of Salvati and other pupils of Michelangelo and Del Sarto. It was about the time when Schoorel, Coxie and Heemskerk, after migrating to Rome and imitating the manner of Poussin, as for many years, came home to execute Dutch-Italian works beneath the level of those produced in the peninsula, as by Leonardo da Pistoia, Nanacci and Rinaldo of Mantua. Fired by these examples, Floris in his turn wandered across the Alps, and appropriated without assimilation the various mannerisms of the schools of Lombardy, Florence and Rome. Bold, quick and resolute, he saw how easy it would be to earn a livelihood and acquire a name by drawing for engravers and painting on a large scale after the fashion of Vasari. He came home, joined the guild of Antwerp in 1546, and quickly opened a school from which 130 disciples are stated to have issued. Floris painted strings of large pictures for the country houses of Spanish nobles and the villas of Antwerp patricians. He is known to have illustrated the fable of Hercules in ten compositions, and the liberal arts in seven, for Claes Jorgeling, a merchant of Antwerp, and adorned the duke of Arschot's palace of Beaumont, with fourteen colossal panels. Comparatively few of his works have descended to us, partly because they came to be condemned for their inherent defects, and so were suffered to perish, partly because they were soon judged by a different standard from that of the Dominicus and the 16th century. The earliest extant canvas by Floris is the "Mars and Venus ensnared by Vulcan" in the Berlin Museum (1547), the latest a "Last Judgment" (1566) in the Brussels gallery. Neither these nor any of the intermediate works at Alost, Antwerp, Copenhagen, Dresden, Florence, Léau, Madrid, St Petersburg and Vienna display any charm of originality in composition or in form. Whatever boldness and force they may possess, or whatever principles they may embody, they are mere appropriations of Italian models spoiled in translation or adaptation. Their technical execution is rapid, but the quality of the lustre of bright colouring; and Floris owed much of his reputation to the cleverness with which his works were transferred to copper by Jerome Cock and Theodorus de Gallo. Whilst Floris was engaged on a Crucifixion of 27 ft., and a Resurrection of equal size, for the grand prior of Spain, he was seized with illness, and died on the 1st of October 1570 at Antwerp.

FLORUS, Roman historian, flourished in the time of Trajan and Hadrian. He compiled, chiefly from Vergil, Livy, a brief sketch of the history of Rome from the foundation of the city to the closing of the temple of Janus by Augustus (25 B.C.). The work, which is called Epitome de T. Livio Bellorum omnium annorum DCC Libri duo, is written in a bombastic and rhetorical style, and is rather a panegyric of the greatness of Rome, whose life is divided into the four periods of infancy, youth, manhood and old age. It is often wrong in geographical and chronological details; but, in spite of its faults, the book was much used in the middle ages. In the MSS. the writer is variously given as Julius Florus, Lucius Annuus Florus, or simply Annaeus Florus. From certain similarities of style he has been identified with Publius Annius Florus, poet, rhetorician and friend of Hadrian, author of a dialogue on the question whether Virgil was an orator or poet, of which the introduction has been preserved. The best editions are those of Jahn (1832), C. Halm (1854), which contain the fragments of the Virgilian dialogue. There is an English translation in Bohn's Classical Library.

FLORUS, JULIUS, poet, orator, and jurist of the Augustan age. His name has been immortalized by Horace, who dedicated to him two of his Epistles (i. 3. ii. 2), from which it would appear that he composed lyrics of a light, agreeable kind. The statement of Porphyrius, the old commentator on Horace, that Florus himself wrote satires, is probably erroneous, but he may have edited selections from the earlier satirists (Ennius, Lucilius, Varro). Nothing is definitely known of his personality, except that he was one of the young men who accompanied Tibullus on his mission to settle the affairs of Armenia. He has been variously identified with Julius Florus, a distinguished orator and uncle of Julius Secundus, an intimate friend of Quintilian (Instit. x. 3. 13); with the leader of an insurrection of the Treviri (Tacitus, Ann. iii. 40); with the Postumus of Horace (Odes, ii. 14) and even with the historian Florus.

FLORUS, PUBLIUS ANNUS, Roman poet and rhetorician, identified by some critics with the historian Florus (q.v.). The introduction to a dialogue called Virgilius orator ad poëta est, in which the author (whose name is given as Publius Annus Florus) states that he was born in Africa, and at an early age took part in the literary contests on the Capitol instituted by Domitian. Having been refused a prize owing to the prejudice against African provincials, he left Rome in disgust, and after travelling for some time set up at Tarraco as a teacher of rhetoric. Here he was persuaded by an acquaintance to return to Rome, for it is generally agreed that it is his poems who wrote the well-known, often quoted, few words in this manner with Hadrian's answer by Aelius Spartanus (Hadrian 16). Twenty-six trochaic tetrameters, De qualitate vitae, and five graceful hexameters, De rosis, are also attributed to him. Florus is important as being the first in order of a number of 2nd-century African writers who exercised a considerable influence on Latin literature, and also the first of the poëtae neronici or novelli (new-fashioned poets) of Hadrian's reign, whose special characteristic was the use of lighter and graceful metres (anapaestic and iambic dimeters), which had hitherto found little favour.

The little poems will be found in E. Bährsen, Poëiae Latinii minores (1853), and for an unlikely identification of Florus with the author of the Persigilia Veneris (1856) see E. H. O. Müller, Der P. Anno Floro poëta et de Persigilia Veneris (1865), and, for the poet's relations with Hadrian, P. Eyzenhardt, Hadriani et Florus (1868), see also F. Marx in Pauly-Wissowa's Realencyclopaedie, i. pt. 2 (1894).

FLOTOW, FRIEDRICH FERDINAND ADOLF VON, FREIHERR (1812-1883), German composer, was born on his father's estate at Teutendorf, in Mecklenburg, on the 27th of April 1812. Destined originally for the diplomatic profession, his passion for music induced his father to send him to Paris to study under Reicha. But the outbreak of the revolution in 1830 caused his return home, where he busied himself writing chamber-music and opetta until he was able to return to Paris. There he produced Pierre et Catherine, Rob Roy, La Duchesse de Guise, but made his first real success with Le Naufrage de la Méduse at the Renaissance Théâtre in 1835. Greater, however, was the success which attended Stradella (1844) and Martha (1847), which made the tour of the world. In 1848 Flotow was again driven home by the Revolution, and in the course of a few years he produced Die Grossfürstin (1850), Indra (1853), Rubezahl (1854), Hilda (1855) and Albin (1856). From 1856 to 1863 he was director (Incendient) of the Schwerin opera, but in the latter year he returned to Paris, where in 1860 he produced L'Ombre. From that time to the date of his death he lived in Paris, or on his estate near Vienna. He died on the 24th of
January 1883. Of his concert-music only the *Jubelvieritüre* is now ever heard. His strength lay in the facility of his melodies.

**FLOTSAM, JETSAM and LIGAN,** in English law, goods lost at sea, as distinguished from goods which come to land, which are technically designated *wreck.* Jetsam (the same as *landed* from *float*, from *float*, Lat. *flottare*) is when goods are cast into the sea, and there sink and remain under water; flotsam (*floatson*, from *float*, Lat. *flottare*) is where they continue floating on the surface of the water; ligian (or *lain*, from *lay or lie*) is where they are sunk in the sea, but tied to a cork or buoy in order to be found again. Flotsams, jetsams and ligans belong to the sovereign in the absence only of the true owner. Wreck, on the other hand (i.e. goods cast on shore), was by the common law adjudged to the sovereign in any case, because it was said by the loss of the ship all property was gone out of the original owner. This singular distinction which treated goods washed ashore as lost, and goods on and in the sea as not lost, is no doubt to be explained by the primitive practice of plundering wrecked ships. (See *Wreck.*)

**FLOUNDER,** a common term for flat-fish. The name is also more specially given to certain varieties, according to local usage. Thus the *Pleuronectes flesus* is the common flounder of English terminology, found along the coasts of northern Europe from the Bristol Channel to Iceland. It is particularly partial to fresh water, ascending the Rhine as far as Cologne. It is eight inches long and both the height and width of its disk. In American terminology the principal fish of the name are the "summer flounders" or "deep-sea flounders," also known in America as "pailce" (Paralichthys dentatus), as long as 3 ft. and as heavy as 15 lb.; the "four-spotted flounders" (*Paralichthys oblongus*); the "common" or "winter" flounder (Pseudopleuronectes americanus); the "diamond flounder" (*Hypopsettula gutulata*); and the "pole flounder" (*Glyptocephalus cynoglossus*).

**FLOUR** and **FLOUR MANUFACTURE.** The term "fLOUR" (Fr. *fleur*, flower, i.e. the best part) is usually applied to the triturated carboinaceous constituents of the wheat berry (see *Wheat*); it is, however, also used of other cereals and even of leguminoids when ground into a fine powder, and of many other substances in a pulvurate state, though in these cases it is usual to speak of rye flour, bean flour, &c. The flour obtained from oats is generally termed oatmeal. In Great Britain wheaten flour was commonly known in the 16th and 17th centuries as meal, and up to the beginning of the 19th century, or perhaps later, the meal terming meal was not infrequently used of the same trade. The ancestor of the millstone was apparently a rounded stone about the size of a man's fist, with which grain or nuts were pounded and crushed into a rude meal. These stones are generally of hard sandstone and were evidently used against another stone, which by dint of continual hammering was broken into hollows. Sometimes the crusher was used on the surface of rocks. St Bridget's stone, on the shore of Lough Macnean, is supposed to have been a primitive Irish mill; there are many depressions in the face of the table-laid rock, and it is probable that round this stone several women (for partly civilisation the preparation of flour was peculiarly the duty of the women) would stand and grind, or rather pound, meal. Many such stones, known as Bullan stones, still exist in Ireland. Similar remains are found in the Orkneys and Shetlands, and it is on record that some of these stones have been used for flour-making within historic times. Richard Bennett in his *History of Corn Milling* remarks that the Seneca Indians to this day boil maize and crush it into a paste between loose stones. In the same way the Omahas pound this cereal in holes in the rocks, while the Oregon Indians parch and pound the capsules of the yellow lil or, much after the fashion described by Herodotus in his account of the ancient Egyptians. In California the Indian squaws make a sort of paste by crushing acorns between a round stone or "muller," and a cuplike hollow in the surface of a rock. Crushing stones are of different shapes, ranging from the primitive ball-like implement to an elongated shape resembling the pestle of a mortar. Mullers of the latter type are not infrequent among prehistoric remains in America, while Dr Schliemann discovered several specimens of the globular form on the reputed site of the city of Troy, and also among the ruins of Mycenae. As a matter of fact stone millers survived in highly civilized countries into modern days, if indeed they are now altogether extinct.

The saddle-stone is the connecting link between the primitive pounder, or muller, and the quern, which was itself the direct ancestor of the millstones still used to some extent in the manufacture of flour. The saddle-stone, the first true grinding implement, consisted of a stone with a more or less concave face on which the grain was spread, and in and along this hollow surface it was rubbed and ground into coarse meal. Saddle-stones have been discovered in the sand caves of Italy, among the lake dwellings of Switzerland, in the dolmens of France, in the pit dwellings of the British Isles, and among the remains of primitive folk all the world over. The Romans of the classical period seem to have distinguished the saddle-stone from the quern. We find allusions to the *mola trusitilis,* which may be translated "the thrusting mill"; this would fairly describe a backwards and forwards motion. The *mola versatilis* evidently referred to the revolving millstone or quern. In primitive parts of the world the saddle-stone is not yet extinct, as for instance in Mexico. It is known as the *metate,* and in the case between the rubbing manger and for making the maize cakes known as tortillas. The same implement is apparently still in use in some parts of South America, notably in Chile. According to Richard Bennett, the quern, the first complete milling machine, originated in Italy and is in all probability not older than the 2nd century B.C. This is, however, a controverted point. Querns are still used in most primitive countries, nor is it certain that they have altogether disappeared from remote districts of Scotland and Ireland. Whatever was their origin, they revolutionized flour milling. The rotary motion of millstones became the essential part of the triturating or grain, and exists to-day in the rolls of the roller mill. The early quern appears to have differed from its descendants in that it was somewhat globular in shape, the lower stone being made conical, possibly with the idea that the ground flour should be provided with a downward flow to enable it to fall from the stones. This type did not, however, persist. Gradually the convexity disappeared and the surface of the two stones became flat or very nearly so. In the upper stone was a species of funnel, through which the grain passed as through a hopper, making its way thence, as the stone revolved, into the space between the running and the bed stone. The ground meal was discharged at the periphery. The runner, or upper stone, was provided with a wooden handle by which the stone was revolved. The typical Roman mill of the Augustan age may be seen at Pompeii. Here, in what is believed to have been a public *pistrinum* or mill, were found four pairs of millstones. The circular base of these mills is 5 ft. in diameter and 1 ft. high, and upon it was fastened the *meta,* a blunt cone about 2 ft. high, on which fitted the upper millstone or *cattillus,* also conical. These mills were evidently rotated by slave labour, and as no mechanism was necessary to drive them while the side-lugs in which the handle-bars were inserted are plainly visible. Slave labour was generally used up to the introduction of Christianity, but was finally abolished by the emperor Constantine, though even after his edict mills continued to be driven by criminals.

The Romans are credited by some authorities with having first applied power to the driving of millstones, which they connected with water-wheels by a horizontal spindle through the intervention of bevel gearing. But long before this mills had been harnessed to water power. Use of power.

The water-mill of the Romans was introduced at a relatively early period into Britain. Domesday Book shows that England was covered by mills of a kind at the time of the Norman conquest, and
mentions some 500 mills in the counties of Norfolk and Suffolk alone. No doubt the mola of Domesday Book consisted of one pair of stones connected by rude gearing with a water-wheel. Windmills are said to have been introduced by the Crusaders, who brought them from the East. Steam power is believed to have been first used in a British flour mill towards the close of the 18th century, when Boulton & Watt installed a steam engine in the Albion Flour Mills, London, erected under the care of John Rennie. Another great engineer, Sir William Fairbairn, in the early days of the 19th century, left the impress of his genius on the mill and all its accessories. He was followed by other clever engineers, and in the days immediately preceding the roller period many improvements were introduced as regards the balancing and driving of millstones. The introduction of the blast and exhaust to keep the stones cool was a great step in advance, while the substitution of silk gauze for woollen or linen bolting cloth, about the middle of the 19th century, marked another era in British milling. Millstones, as used just before the introduction of roller milling, were from 4 to 4 1/2 ft. in diameter by some 12 in. in thickness, and were usually made of a siliceous stone, known as buhr-stone, much of which came from the quarry of La Ferté-sous-Jouarre, in France.

Nine-tenths, or perhaps ninety-nine hundredths, of all the flour consumed in Great Britain is made in roller mills, that is, mills in which the wheat is broken and flouried by means of rollers, some grooved in varying degrees of fineness, some smooth, their work being preceded and supplemented by a wide variety of other machines and processes. All roller mills worthy of the name are completely automatic, that is to say, from the raw material enters the mill warehouse till it is sacked, whether in the shape of finished flour or of offals, it is touched by no human hand.

The history of the roller milling extends back to the first half of the 19th century. Roller mills, that is to say, machines fitted with rolls set either horizontally, or vertically, or obliquely, for the grinding of corn, are said to have been used as far back as the 17th century, but if this be so it is certain that they were only used in a tentative manner. Towards the middle of the 19th century the firm of E. R. & F. Turner, of Ipswich, began to build roller mills for breaking wheat as a preliminary to the conversion of the resultant middlings on millstones. The rolls were made of chilled iron and were provided with serrated edges, which must have exercised a treading action on the integuments of the berry. These mills were built to the design of a German engineer, of the name of G. A. Buchholz, and were exhibited at the London exhibition of 1862, but they never came into general use. It has also been stated that as early as 1823 a French engineer named Collier, of Paris, patented a roller mill, while five years later a certain Malar took out another French patent, the specification of which speaks of grooves and differential speeds. But the direct ancestors of the roller mills of the present day were brought out some time in the third decade of the 19th century by a Swiss engineer named Sulzberger. His apparatus was rather cumbersome, and the chilled iron rolls with which it was fitted consumed a large amount of power relatively to the work effected. But the Pester Wals-Mühle, founded in 1830 by Count Waliszewski, a Hungarian nobleman, which took its name from the roller mills with which it was equipped by Sulzberger, was for many years a great success; some of its roller mills are said to have been kept at work for upwards of forty years, and one at least is preserved in the museum at Budapest.

It may be noted that Hungarian wheat is hard and flinty and well adapted for treatment by rolls. Moreover, gradual reduction, as now understood, was more or less practised in Hungary, even before the introduction of roller milling. Though millstones and not rolls were used, yet the wheat was not flouried at one operation, as in typical low or flat grinding, but was reduced to flour in several successive operations. In the first break the stones would be placed just wide enough apart to "end" the wheat, and in each succeeding operation the stones were brought closer together. But Hungarian milling was not then automatic in the sense in which British millers understand the word. For a long time a great deal of hand labour was employed in the merchant mills of Budapest in carrying about products from one machine to another for further treatment. This practice may have been partly due to the cheap labour available, but it was also the deliberate policy of Hungarian millers to handle in this way the middlings and fine "dunst," because it was maintained that only thus could certain products be delivered to the machine by which they were to be treated in the perfection of condition. The results were good so far as the finished products were concerned, but in the light of modern automatic milling the system appears uneconomical. Not only did it postulate an inordinately large staff, but it further increased the labour bill by the demand it made on the number of sub-foremen who were occupied in classifying, largely by touch, the various products, and directing the labourers under them. Hungarian milling still differs widely from milling as practised in Great Britain in being a longer system. This is due to the more minute subdivision of products, a necessary consequence of the large number of grades of flour and offals made in Hungary, where there are many intermediate varieties of middlings and "dunst" for which no corresponding terms are available in an English miller's vocabulary.

It will be convenient here to explain the meaning of three terms constantly used by millers, namely, semolina, middlings and dunst. These three products of roller mills are practically identical in composition, but represent different stages in the process of reducing the endosperm of the wheat into flour. A wheat berry is covered by several layers of skin, while under these layers is the floury kernel or endosperm. This the break or grooved rolls tend to tear and break up. The largest of these more or less cubical particles are known as semolina, whilst the medium-sized are called middlings and the smallest sized termed dunst. The last is a German word, with several meanings, but is used in this particular sense by German and Austrian millers, from whom it was doubtless borrowed by the pioneers of roller milling in England. If we were to lay a sample of fairly granular flour beside a sample of small dunst the two would be easy to distinguish, but place a magnifying glass over the flour and it would look very like the dunst. If we were to repeat this experiment on dunst and fine middlings, the former would under the glass present a strong resemblance to the middlings. The same effect would be produced by the putting side by side of large middlings and small semolina. This is a broad description of semolina, middlings and dunst. Semolina and middlings are apt to vary in appearance; that is dunst, because what is the product of the later stages of the milling process and represents small particles of the floury kernel tolerably free from imperities as bran or fluff. The flour producing middlings must not be confounded with the variety of wheat offal which is also known to many English millers as middlings. This consists of husk or bran, more or less comminuted, and with a certain proportion of floury particles adherent. It is only fit for feeding beasts.

The spread of roller milling on the continent of Europe was undoubtedly accelerated by the invention of porcelain rolls, by Friedrich Wegmann, a Swiss miller, which were brought into general use in the seventh decade of the 19th century, and are still widely employed. They are admirably fitted for the reduction of semolina, middlings and dunst into flour; and for reducing pure middlings, that is, middlings containing no bran or wheat husk, there is perhaps nothing that quite equals them. They were introduced into Great Britain in 1877, or thereabouts, and were used for several years in most of the tall millstone mills. This was partly due to the fact that as made at that date they were rather difficult to work, as it was not easy to keep the rolls perfectly parallel. Another drawback was their inadaptability to over-heavy feeds, to which the British, and perhaps still more the American, miller is frequently obliged to resort. However, since the beginning of the 20th century some of the most advanced flour mills in England have again
taken to use porcelain rolls for some part of their reduction process.

The birth of roller milling in Great Britain may be said to date from 1872, when Oscar Oexle, a German milling engineer, erected a set of roller mills in the Tradeston Mills, in Glasgow. This was long before the introduction of automatic roller mills. But the foundations of the Transean Mills system were not seriously disturbed till 1877, when a party of leading British and Irish millers visited Vienna and Budapest with the object of studying roller milling in its native home. In 1878 J. H. Carter installed in the mill of J. Boland, of Dublin, what was probably the first complete automatic roller plant erected in the United Kingdom, and in 1881 a milling exhibition held at the Royal Agricultural Hall, London, showed the automatic roller system in complete operation. From that time the roller system made great progress. By 1885 many of the leading British millers had installed full roller plants, and in the succeeding ten years small roller plants were installed in many country mills. For a time there was a transition stage in which there was in operation a number of so-called "combined" plants, that is to say, mills in which the wheat was broken on millstones or disk mills, while the middlings were reduced by smooth rolls; but these gradually dropped out of being.

Well-found British flour mills at the present time are probably the best fitted in the world, and as a whole have nothing to fear from comparison with their American competitors. It is true that operations outside the system throughout the berry, but are milling methods so far as gradual reduction was concerned. But from about 1886 the British miller was quite awake to his position and was striving every nerve to provide himself with a plant capable of dealing with every kind of wheat. It has often been said that he commands the wheat of the whole world. This is true in a sense, but it is not true that he can always command the exact kind of wheat he requires at the price required to meet foreign competition. Therein he is at a disadvantage. But engineers have done their best to meet this weak point, and by their assistance he is able to compete under almost all conditions with the millers of the whole world.

Processes of Milling.—Fully to appreciate the various processes of modern milling, it must be remembered not only that the wheat as delivered at the mill is dusty and mixed with sand and even more objectionable refuse, but also that it contains many light grains and seeds of other plants. It is not therefore sufficient for the miller to be able to reduce the grain to flour on the most approved principles; he must also have at command the means of freeing it from foreign substances, and of "conditioning" it, so as to be dry or over dry and floury. Ancient and primitive, characterized by its dependence on the texture of the wheat grain. The wheat berry is a fruit, not a seed, the actual seed being the gum or embryo, a kidney-shaped body which is found at the base of the berry and is connected with the plumule or root. The gum is tough in texture and is in roller milling easily separated from the rest of the berry, being flattened instead of crushed by the rolls and thus readily sifted from the stock. The germ contains a good deal of fatty matter, which, if allowed to remain, would not increase the keeping qualities of the flour. Botanists distinguish five skins on the berry—pericarp, epicarp, endocarp, episperm and embryous membrane—but for practical purposes the number of integuments may be taken as three. The inner skin is often as thick as the outer and second skins together, which are largely composed of woody fibre; it contains the cereal or aleurone cells, but although these are made up of a certain proportion of proteids, on account of the discolouring and diastasic action of the cerealin in flour they are best eliminated. The endosperm, or floury kernel, coming next to the inner skin, consists of starch granules which are caught as it were in the minute meshes of a net. This network is the gluten, and it may be noted that these meshes are not of the usual fibrous nature occurring in the berry but are usually finer and more dense near the husk than in the interior of the kernel. This glutinous portion is of great importance to the baker because on its quantity and quality depends the "strength" or rising power of the flour, and the aim of modern roller milling is to retain it as completely as possible, a matter of some difficulty owing to its close adherence to the husk, especially in the richest wheats. Another organ of the wheat berry which has a most important bearing on the work of the miller is the pericarp or shell, the outer covering of the berry with its stalk or straw. The pericarp serves to filter the food which the plant sucks up from the ground; it passes up the crease of the berry, and is enclosed in the middle skin, being protected on the outer side by the husk and on whatever side by the outer skin on its other side. A good deal of the matters filtered by the pericarp are mineral in their nature, and such portions as are not digested remain in the crease. This is the matter which millers call "crease dirt." It is highly discolouring to flour, and must be carefully eliminated. The fuzzy end of the berry known as the beard also has a distinct function; its hairs are in reality tubes which serve to carry off superfluous moisture. They have, in common with the bran, no nutritive value. (See also Wheat.)

In the old "flat" or "low" milling the object was to grind as perfectly as possible, at one operation, the cerealin, or germ of the grain, constituting the flour, and to separate it from the embryo and outer skins constituting the bran. In "high" milling, on the other hand, the grinding is effected in a series of operations, the aim being to as much as possible disintegrate the middling as possible. The results may be obtained by breaking the wheat, and to make as little flour as possible during the earlier or "breaking" part of the process. It is impossible altogether to avoid the breaking of the wheat, and, in fact, the broken rolls will make as little as 15% of "break-flour," which is of less value, being contaminated with crease dirt, and also because it is weak owing to the absence of the gluten cells which are more readily to the middlings of whole wheat. The middlings, times called Graham flour, consists of the entire grain ground up to a uniform mass.

Milling has been well called the foundation of all good milling. In the screen house, as the wheat-cleaning department of the mill is termed, will be found an array of machinery almost equal in range and variety to that in the mill wheel. Before the wheat, drawn out from the barn or hoisted in sacks, is first treated by a machine known as a warehouse separator. This apparatus accomplishes its work by means of screens, some of which will be of much coarser mesh than others, and of air currents, the adjustment of which is a more delicate task than might appear. The warehouse separator serves to free dirty wheat of such impurities as lumps of earth, stones, straws and the like. Mention should be made here of the great break Great care has to be exercised in all operations of the screen house lest wheat should pass away with the screenings. Besides the warehouse separator, which is made in different types and sizes, a machine known as a sorter is used. This consists of a number of cylinders, usually made of bronze, and which are accurately polished, and are set at a slight tilt in the frame. The cylinders are provided with windings so shaped and of such size as to catch the grains of wheat, and to separate them out according to the size of the grains. These are variously termed oat, which are longer than wheat. Sorting cylinders should be followed by machines known as scours, the function of which is to free the wheat from adherent impurities. These machines are of different types, but all depend on a similar action. A vertical scourer consists of a number of steel or iron beaters attached to a vertical spindle which revolves inside a metallic woven or perforated casing, the whole being fitted with an effectual exhaust. Scours with horizontal spindles are also in great favour. Not every wheat is suitable for scouring, but some wheats are so mingled with impurities that a severe action between the beaters and the perforated casing is absolutely necessary. The most effective of all scours frees the wheat from the greatest amount of impurity with a minimum of abrasion. The beaters should be adjustable to suit different kinds of wheat. Scours are followed by brush machines in which the grain is agitated and disturbed by a series of rubber or bristle brushes, or by fans, which are used to carry away the waste matter without disturbing the grain. The material is then again subjected to a second brushing, and is then conveyed to the sifting and cleaning department.
be of horseshoe shape, in which case they are usually set at the head of the dryer. In another case, they may consist of magnetized plates set at angles over which the wheat is passed. This is not a bad arrangement, for it places the magnets just before the first set of break-rods, where they should ensure the arrest of steel and iron particles, which might otherwise pass into the flour and roll with the edges of the grain, and also do damage to the sifting machines. Mention may also be made of the automatic scales which are used to check the milling value of the wheat. In principle these machines are all the same, though the disposition and arrangement of the parts varies with the weight of grain. As soon as the receiving hopper has poured through a valve into the recipient or skip, which is hung at one end of the machine, or lead to overcome the weight hung at the other end of the beam, the inlets of granary is automatically cut off and the skip is discharged, automatically returning to take another charge. Each weighing is automatically recorded on a chart which records a bar for each bushel of unmilled or cleaned wheat entering the warehouse and of the net weight of the cleaned wheat. The difference between the two weighings will be at the loss by cleaning. The percentage of flour obtained from a given Wheat is ascertainable in the mill itself. In practice the second weigher is placed just before the first break.

The cleaning of wheat by washing only became a fine art at the close of the 19th century, though it was practised in the north of England some twenty years earlier. Briefly it may be said that certain wheats are washed to free them from extraneous matter, while in others washing is adopted for the purpose of removing the wheat which could not be removed by dry cleaning without undue abrasion. Such wheats are Indians, Persians and hard Russian wheats, and it is usual to wash, or purify, or blend, a soft wheat, by which is meant dehulling, before going to the rolls. With another class of wheats, such as the softer Russians and Indians, spring Americans and Canadians, hard American winters, Californian and River Plate wheats, it is found that the heat is also desirable, though care must be exercised not to let the moisture penetrate into the endosperm or flour portion of the kernel, and even distinct class soft wheats, such as many kinds of Flours, soft Russians and English wheats, are generally admitted that while wheat of the first two divisions will benefit from the application of both moisture and heat, wheat of the third class must be washed with great circumspection. The descending machines is to agitate the wheat in water in which the adherent foreign matters are washed off and any dirt balls broken up and drained off in the waste water. To this end some washers are fitted with Archimedean screws, which either all go or slide horizontally or vertically; or the washer may consist of a barrel revolving in a tank partly filled with water. Another function of washing machines is to separate stones of the same size which are found in several varieties of wheat. This separation is effected by utilizing a current of water as a balance strong enough to carry wheat but not strong enough to carry stones or bodies of greater specific gravity that might be present in the grain. There may be a perforated floor or draw horizontally over a revolving tray. The washer is followed by a whizzer, which is an apparatus intended to free the berry by puree mechanism of the extraneous matter. When the case is thoroughly washed, while the water passes in a vertical column fed at the bottom and delivered at the top. The wet wheat ascends by centrifugal force in a spiral direction round the column to the top, and by the time it is discharged from the whizzer it is through a certain percentage of its moisture. In all its moisture, the water escaping through the perforated cover of the machine. But there still remains a certain amount of water which has penetrated the integuments more or less deeply, and to flour the berry it is necessary to subject it to a greater or less degree of hot and cold air.

The wheat is passed between perforated metal plates and subjected to a draught first of hot and then of cold air. The perforated plates are usually built in the shape of a column, or leg as it is often called, and this is provided with two air chambers, an upper one serving as a reservoir for hot, and the lower for cold air. The air from both chambers is discharged by pressure through the perforated sides of the column, which must be made of steel or iron and so thick that the air is drawn in by a steel-plate fan, which is often provided with a divided casing, one side being used for hot and the other for cold. Coupled with the hot air side is a heater of a proper temperature for the purpose of vaporizing the moisture. The temperature of the heated air can be regulated by the supply of steam to the heater. This process of washing and conditioning, one of the most important in the mill, is characteristically British; mills have to deal with wheats of the most varied nature, and one object of conditioning is to bring hard and harsh, soft and weak wheats as nearly as possible to a common standard of condition before they pass into the flour mill. There are three ways of achieving this; the first is to change the temperature of the grain, the second is to change the moisture content, the third is to change the shape of the grain. The first is known as conditioning, consists of injecting steam into wheat as it passes through a metal hopper. Here the object is to change to some extent, and to warm and soften (by the condensate being the principal substances used for a full washing and conditioning plant. Hard wheats will be not injured by a fairly long im-

length 9 in. is the usual diameter; for longer rolls 10 in. is the
standard. To do good work rolls must run in perfect parallelism
otherwise some parts of the material will pass untouched, while
others will be treated too severely.
The products of the break-rolls are treated by what are known
as scalpers, which are simply machines for sorting out these products
for further treatment. Scalpers may either be revolving

next break. The
throughs," or what has passed this sieve, are
graded by the next sieve, the tailings going to a purifier, while the
throughs may be freed from what flour adheres to them by a centrifugal dressing machine and then treated by another purifier. A
form of scalper which has come into general use on the continent
of Europe, and to a lesser extent in Great Britain and America, is
known as the plansifter. This machine, of Hungarian origin, is
simply a collection of superimposed flat sieves in one box, and will
scalp or sort out any kind of break stock very efficiently. A system
of grading the tailings, that is, the rejections of the scalpers, introduced by James Harrison Carter (Carter-Zimmer patent), was known
as pneumatic sorting. Its object was to supplement the work of
the scalpers by classifying the tailings by means of air-currents.
To this end each scalper was followed by a machine arranged somewhat like a gravity purifier; that is to say, a current of air drawn
through the casing of the sorter allowed the heaviest and best
material to drop down straight, while the lighter stuff was deposited
in one or other of further compartments formed by obliquely placed
adjustable cant boards. So searching was this grading, that from
the first sorter of a four-break plant four separations would be
obtained, the first going to the second break, the second joining the
first separation from the second sorter and being fed to the third
break, while the third went with the best separation of the third
sorter to the fourth break, and the last separation from all the
sorters went straight into the bran sack. The work of the breakrolls was greatly simplified and reduced
by this sorting process, as
each particle of broken wheat went exactly to that pair of breakrollers for which it was suitable, instead of all the material being
run indiscriminately through all the break-rollers and thereby being
cut up with the necessary result of increasing the production of
small bran.
The object of the purifier, a machine on which milling engineers
have lavished much thought and labour, is to get away from the
_
semolina and middlings as much impure matteras possible,
that those products may be pure, as millers say, for
reduction to flour by the smooth rolls. The purifiers used in British
mills take advantage of the fact that the more valuable portions of
the wheat berry are heavier than the less valuable particles, such as
bran and fibrous bodies, and a current of air is employed to weigh
these fragments of the wheat berry as in a balance and to separate
them while they pass over a silk-covered sieve. To this end the
semolina or middlings are fed on a sieve vibrated by an eccentric
and set at a slight downward angle. This sieve is installed in an
air-tight longitudinal wooden chamber with glass windows on either
side, through which the process of purifying can be watched. Upwards through this sieve a fan constantly draws a current of air,
which, raising the stock upwards, allows the heavier and better
material to remain below while the lighter particles are lifted off
and fall on side platforms or channels, whence they are carried
forward and delivered separately. The good material drops through
the meshes of the silk, and is collected by a worm. It is usual to
clothe the sieve in sections with several different meshes of silk so
that stock of almost identical value, but differing size, may be

preceding machines. Repurification and even tertiary purification
may be necessary under certain conditions. In Hungary and other
are much in use. Here the material
parts of Europe, gravity purifiers
is guided along an open sieve set at a slight angle, while an aircurrent is drawn up at an acute angle. Under the sieve may be arranged a series of inclined boards, the position of which can be varied
as required. The heaviest and most valuable products resist the
current and drop straight down, while lighter material is carried
off to further divisions.
From the purifier all the stock except the tailings, which may
require other treatment, should go to the smooth rollers to be made

great care and discretion. Many of the remarks already
rolls
made in regard to break-rolls apply to smooth rolls,
notably in respect of parallelism. But instead of a cutting action,
the smooth rolls press the material fed to them into flour. This
pressure, however, must be applied with great discrimination, large
semolina with impurities attached requiring quite different treatment from that called for by small pure middlings. The pressure on
;

%

'

the stock must be just sufficient and no more. Reduction rolls are
usually run at a differential speed of about 2 to 3. The feed must be
carefully graded, because to pass stock of varying size through a
pair of smooth rolls would be fatal to good work. Scratch rolls very
finely grooved are used for cracking impure semolina or for reducing
the tailings of purifiers. The latter often hold fragments of bran,
which are best detached by rolls grooved about 36 to the inch and
run at a differential of 3 to I. The reduction requires even more
roll surface than the break system.
To do first-class work a mill
should have at least 35 to 40 in. on the breaks and 50 in. on the
reduction for each sack of 280 ft of flour per hour. Many engineers
consider 100 to 1 10 in. on the break, scratch and smooth rolls not
too much.
The dressing out of the flour from the stock reduced on smooth
rolls is generally effected by centrifugal machines, which consist
of a slowly revolving cylinder provided with an internal
-^
shaft on which are keyed a number of iron beaters that
run at a speed of about 200 revolutions a minute, and fling the feed
against the silk clothing of the cylinder. What goes through the silk
is collected by a worm conveyor at the bottom of the machine.
Most centrifugals have so-called " cut-off " sheets, with internal
divisions in the tail end
these are intended to separate some
intermediate products, which, having been freed fromfloury particles,
are treated on some other machine, such as a pair of rolls either
direct or after a purifier. The centrifugal is undoubtedly an efficient
flour separator, but the plansifters already mentioned are also good

gets more sticky and requires more severe treatment.

The yield of flour obtained in a British roller mill averages 70 to
of the wheat berry. The residue, with the exception of a very
73
small proportion of waste, is offal, which is divided into various
grades and sold. Profitable markets for British-made bran have
been found in Scandinavia, and especially in Denmark. In millstone milling the yield of flour probably averaged 75 to 80 %, but
a certain proportion of this was little more than offal. The length of
the flour yield taken by British millers varies in different parts of

patents may be at a premium in another the call is for a straight
grade, i.e. a flour containing as much of the farinaceous substance
as can be won from the wheat berry. In one district there is a sale
for rich offals, that is, offals with plenty of flour adhering in another
there may be no demand for such offals. Hence, though the general
principles of roller milling as given above hold good all over the
country, yet in practice the work of each mill is varied more or less
to suit the peculiarities of the local trade.
Early in the io.th century a French chemist, J. J. E. Poutet,
discovered that nitrous acid and oxides of nitrogen act on some
.
fluid and semi-fluid vegetable oils, removing their yellow

the wheat itself rather than on the flour. In 1879 a process was
patented for bleaching grain by means of chlorine, gas, and about
1891 a suggestion was made for bleaching grain by means of electroIn 1895 a scheme was put forward for treating
lysed sea-water.
grain with sulphurous acid, and about two years later it was proposed to subject both grain and flour to the influence of electric
currents. In 1893 a patent was granted for the purification of flour
by means of fresh air or oxygen, and three years later another inventor proposed to employ the Rontgen rays for the same purpose.
In 1898 Emile Frichot took out a patent for using ozone and ozonized
air for flour-bleaching. The patent (No. 1661 of 1901) taken out by
J. & S. Andrews of Belfast recited that flour is known to improve
greatly if kept for some time after grinding, and the purpose of the
invention it covered was to bring about this improvement or conditioning not only immediately after grinding, but also to a greater
extent than can be effected by keeping. The process consisted in
subjecting the flour to the action of a suitable gaseous oxidizing
medium; the inventors preferred air carrying a minute quantity
of nitric acid or peroxide of nitrogen, but they did not confine themselves to those compounds, having found that chlorine, bromine
and other substances capable of liberating oxygen were also more
or less efficacious. They claimed that while exercising no deleterious
action their treatment made the flour whiter, improved its baking
qualities, and rendered it less liable to be attacked by mites or other
organisms. Under the patent, No. 14006 of 1903, granted to J. N.
Alsop of Kentucky the flour was treated with atmospheric air
which had been subjected to the action of an arc or, flaming disof purifying it and improvcharge of electricity, with the purpose

ing its nutritious properties.
became the objects of extended litigation in the English courts,
and it was held that the gaseous medium employed by Alsop was
substantially the same as that employed by Andrews, though
produced electrically instead of chemically, and therefore that the
Alsop process was an infringement of the Andrews patent. Various
other patents for more or less similar processes have also been taken
out.

FLOURENS—FLOWER

FLOURENS, GUSTAVE (1838-1871), French revolutionist and writer, a son of J. P. Flourens (1794-1867), the physiologist, was born at Paris on the 4th of August 1838. In 1863 he undertook for his father a course of lectures at the Collège de France, the subject of which was the history of mankind. His theories as to the manifold origin of the human race, however, gave offence to the clergy, and he was precluded from delivering a second course. He then went to Brussels, where he published his lectures under the title of Histoire de l'homme (1863); he next visited Constantinople and Athens, took part in the Cretan insurrection of 1866, spent some time in Italy, where an article of his in the Popolo d'Italia caused his arrest and imprisonment, and finally, having returned to France, nearly lost his life in a duel with Paul de Cassagnac, editor of the Pays. In Paris he devoted his pen to the cause of republicanism, and at length, having failed in an attempt to organize a revolution at Belleville on the 7th of February 1870, found himself compelled to flee from France. Returning to Paris on the downfall of Napoleon, he soon placed himself at the head of a body of 500 tirailleurs. On account of his insurrectionary proceedings he was taken prisoner at Créteil, near Vincennes, by the provisional government, and confined at Mazas on the 7th of December 1870, but was released by his men on the night of January 21-22. On the 18th of March he joined the Communists. He was elected a member of the commune by the 20th arrondissement, and was named colonel. He was one of the most active leaders of the insurrection, and in a sortie against the Versailles troops in the morning of the 3rd of April was killed in a hand-to-hand conflict at Rueil, near Maureilhan, henceforth known as Flourens. Gustave Flourens was the author of numerous fugitive pamphlets.

See C. Proélès, Les Hommes de la révolution de 1871 (Paris, 1898).

FLOURENS, MARIE JEAN PIERRE (1794-1867). French physiologist, was born at Maureilhan, near Béziers, in the department of Hérault, on the 15th of April 1794. At the age of fifteen he began the study of medicine at Montpellier, where in 1823 he received the degree of doctor. In the following year he repaired to Paris, provided with an introduction from A. P. de Candolle, the botanist, to Baron Cuvier, who received him kindly, and interested himself in his welfare. At Paris Flourens engaged in physiological research, occasionally contributing to literary publications; and in 1821, at the Athénées there, he gave a course of lectures on the physiological theory of the sensations, which attracted much attention amongst men of science. His paper entitled Recherches expérimentales sur les propriétés et les fonctions du système nerveux dans les animaux verités, in which he, from experimental evidence, sought to assign their special functions to the cerebrum, corpora quadrigemina and cerebellum, was the subject of a highly commendatory report by Cuvier, adopted by the French Academy of Sciences in 1822. He was chosen by Cuvier in 1828 to deliver for him a course of lectures on natural history at the Collège de France, and in the same year became, in succession to L. A. G. Bosc, a member of the Institute, in the division "Économie rurale." In 1830 he became Cuvier's substitute as lecturer on human anatomy at the Jardin du Roi, and in 1832 was elected to the post of Titular professor, which he vacated for the professorship of comparative anatomy created for him at the museum of the Jardin the same year. In 1833 Flourens, in accordance with the dying request of Cuvier, was appointed a perpetual secretary of the Academy of Sciences; and in 1836 he was returned as a deputy for the arrondissement of Béziers. In 1840 he was elected, in preference to Victor Hugo, to succeed J. F. Michaud at the French Academy; and in 1845 he was created a commander of the legion of honour, and in the next year a peer of France. In March 1847 Flourens directed the attention of the Academy of Sciences to the anaesthetic effect of chloroform on animals. On the revolution of 1848 he withdrew completely from political life; and in 1855 he accepted the professorship of natural history at the Collège de France. He died at Montgomer, near Paris, on the 4th of August 1867.

Besides numerous shorter scientific memoirs, Flourens published—Essai sur quelques points de la doctrine de la révolution et de la dérivation (Montpellier, 1813); Experiences sur le système nerveux (Paris, 1825); Cours sur la génération, l'âgeologie, et l'embryologie (1836); Analyse raisonnée des travaux de G. Cuvier (1841); Recherches sur le développement des os et de la duré de leurs bases, et des membres nuqueux (1843); Buffon, histoire de ses travaux et de ses idées (1844); Fontenelle, ou de la philosophie moderne relativement aux sciences physiques (1847); Théorie expérimentale de la longévité (1850); Hositoire de la découverte de la circulation du sang (1854); Dictionnaire de Physiologie et de Phystologie des animaux inferieurs (1856): De la vie et de l'intelligence (1858); De la raison, du génie, et de la foi (1861); Ontologie naturelle (1861); Examen du livre de M. Dorson sur l'origine des Épées (1864). For a list of his papers see the Royal Society's Catalogue of Scientific Papers.

FLOWER, SIR WILLIAM HENRY (1831-1889), English botanist, was born at Stratford-on-Avon on the 30th of November 1831. Choosing medicine as his profession, he began his studies at University College, London, where he showed special aptitude for physiology and comparative anatomy and took his M.B. degree in 1851. He then joined the Army Medical Service, and went out to the Crimea as an assistant-surgeon, receiving the medal with four clasps. On his return to England he became a member of the surgical staff of the Middlesex Hospital, London, and in 1861 succeeded J. T. Queckett as curator of the Hunterian Museum of the Royal College of Surgeons of England. In 1870 he also became Hunterian professor, and in 1884, on the death of Sir Richard Owen, was appointed to the directorship of the Natural History Museum at South Kensington. He died in London on the 1st of July 1889. He made valuable contributions to structural anthropology, publishing, for example, complete and accurate measurements of no less than 1500 human skulls, and as a comparative anatomist he ranked high, devoting himself especially to the study of the mammalia. He was also a leading authority on the arrangement of museums. The greater part of his life was spent in their administration, and in consequence he held very decided views as to the principles upon which their specimens should be set out. He insisted on the importance of distinguishing between collections intended for the use of specialists and those designed for the Instruction of the general public, pointing out that it was as futile to present to the former a number of merely typical forms as to provide the latter with a long series of specimens differing only in the most minute details. His ideas, which were largely and successfully applied to the museums of which he had charge, gained wide approval, and his influence entitles him to be looked upon as a reformer who did much to improve the methods of museum arrangement and management. In addition to numerous original papers, he was the author of An Introduction to the Osteology of the Fishes (1879); Flower: the Introduction to the Study of Mammals, Living and Extinct (1883); Essays on Museums and other Subjects (1868). He also wrote many articles for the ninth edition of the Encyclopaedia Britannica.

FLOWER (Lat. fl. floris; Fr. fleur), a term popularly used for the bloom or blossom of a plant, and so by analogy for the fairest, choicest or finest part or aspect of anything, and in various technical senses. Here we shall deal only with its botanical sense. It is impossible to give a rigid botanical definition of the term "flower." The term is a characteristic of the highest group of the plant kingdom—the flowering plants (Phanerogams)—and is the name given to the association of organs, more or less leaf-like in form, which are concerned with the production of the fruit or seed. In modern botanical works the group is often known as the seed-plants (Spermatophyta). As the seed develops from the ovule which has been fertilized by the pollen, the essential structures for seed-production are two, viz. the pollen-hearer or stamen and the ovule-hearer or carpel. These are with few exceptions fleshy structures, known in comparative morphology as sporophylls, because they bear the spores, namely, the microspores or pollen-grains which are developed in the microспорangia or pollen-sacs, and the megaspore, which is contained in the ovule or megasporangium.

In Gymnosperms (p.s.), which represent the more primitive
FLOWER

The flower of seed-plants, the micro- or macro-sporophylls are generally associated, often in large numbers, in separate cones, to which the term “flower” has been applied. But there is considerable difference of opinion as to the relation between these cones and the more definite and elaborate structure known as the flower in the higher group of seed-plants—the Angiosperms (q.v.)—and it is to this more definite structure that we generally refer in using the term “flower.”

Flowers are produced from flower-buds, just as leaf-shoots arise from leaf-buds. These two kinds of buds have a resemblance to each other as regards the arrangement and the development of their parts; and it sometimes happens, from injury and other causes, that the part of the axis which, in ordinary cases, would produce a leaf-bud, gives origin to a flower-bud. A flower-bud has not in ordinary circumstances any power of extension by the continuous development of its apex. In this respect it differs from a leaf-bud. In some cases, however, of monstrosity, especially seen in the rose (fig. 1), the central part is prolonged, and bears leaves or flowers. In such cases the flowers, so far as their functional capabilities are concerned, are usually abortive. This phenomenon is known as proliferation of the floral axis.

Flower-buds, like leaf-buds, are produced in the axil of leaves, which are called bracts.

The term bract is properly applied to the leaf from which the primary floral axis, whether simple or branched, arises, while the leaves which arise on the axis between the bract and the outer envelope of the flower are bracteoles or bractelets. Bracts sometimes do not differ from the ordinary leaves, as in Veronica hederifolia, Vinca, Anagallis and Ajuga. In general as regards their form and appearance they differ from ordinary leaves, the difference being greater in the upper than in the lower branches of an inflorescence. They are distinguished by their position at the base of the flower or flower-stalk. Their arrangement is similar to that of the leaves. When the flower is sessile the bracts are often applied closely to the calyx, and may thus be confounded with it, as in the order Malvaceae and species of Dianthus and winter aconite (Erantis), where they have received the name of epicalyx or calycus. In some Rosaceous plants an epicalyx is present, due to the formation of stipular structures by the sepals. In many cases bracts act as protective organs, within or beneath which the young flowers are concealed in their earliest stage of growth.

When bracts become coloured, as in Amherstia nobilis, Emphorbia splendens, Erica elegans and Salvia splendens, they may be mistaken for parts of the corolla. They are sometimes mere scales or threads, and at other times are undeveloped, giving rise to the bracteate inflorescence of Cruciferae and some Boraginaceae. Sometimes they are empty, no flower-buds being produced in their axil. A series of empty coloured bracts terminates the inflorescence of Salvia Horminum. The smaller bracts or bracteoles, which occur among the subdivisions of a branching inflorescence, often produce no flower-buds, and thus anomalies occur in the floral arrangements. Bracts are occasionally persistent, remaining long attached to the base of the peduncles, but more usually they are deciduous, falling off early by an articulation. In some instances they form part of the fruit, becoming incorporated with other organs. Thus, the cones of firs and the stroboli of the hop are composed of a series of spirally arranged bracts covering fertile flowers; and the scales on the fruit of the pine-apple are of the same nature. At the base of the general umbel in umbelliferous plants a whorl of bracts often exists, called a general involucel, and at the base of the smaller umbels or umbellules there is a similar leafy whorl called an involucel or partial involucel. In some instances, as in fool’s-parsley, there is no general involucel, but simply an involucel; while in other cases, as in fennel or dill (fig. 15), neither involucel nor involucel is developed. In Compositae the name involucel is applied to the bracts surrounding the head of flowers (fig. 2, i), as in marigold, dandelion, daisy, artichoke. This involucel is frequently composed of several rows of leaflets, which are either of the same or of different forms and lengths, and often lie over each other in an imbricated manner. The leaves of the involucel are spiny in thistles and in teasel (Dipsacus), and hooked in burdock. Such whorled or verticillate bracts generally remain separate (polyphyllous), but may be united by cohesion (gemiphylous), as in many species of Buphleum and in Lavatera. In Compositae besides the involucel there are frequently chaffy and setose bracts at the base of each flower, and in Dipsacaceae a membranous tube surrounds each flower. These structures are of the nature of an epicalyx.

In the acorn the cupule or cup (fig. 3) is formed by a growing upwards of the flower-stalk immediately beneath the flower, upon which scaly or spiny protuberances appear; it is of the nature of bracts. Bracts also compose the husky covering of the hazel-nut.

When bracts become united, and overlie each other in several rows, it often happens that the outer ones do not produce flowers, that is, are empty or sterile. In the artichoke the outer imbricated scales or bracts are in this condition, and it is from the membranous white scales or bracts (paleae) forming the choke attached to the edible receptacle that the flowers are produced. The sterile bracts of the daisy occasionally produce capitula, and give rise to the hen-and-chickens daisy. In place of developing flower-buds, bracts may, in certain circumstances, as in profliferous or viviparious plants, produce leaf-buds.

A sheathing bract enclosing one or several flowers is called a spadix. It is common among Monocotyledons, as Narcissus (fig. 4), snow-flake, Arum and palms. In some palms it is 20 ft. long, and enclosed 200,000 flowers. It is often associated with that form of inflorescence termed the spadix, and may be coloured, as in Anthurium, or white, as in arum lily (Richardia aethiopicia). When the spadix is compound or branching, as in palms, there are smaller spathes, surrounding separate parts of the inflorescence. The spathe protects the flowers in their young state, and often falls off after they are developed, or hangs down...
in a withered form, as in some palms, Typha and Pothos. In
grasses the outer scales or glumes of the spikelets are sterile
bracts (fig. 5, gl); and in Cyperaceae bracts enclose the organs
of reproduction. Bracts are frequently changed into com-
plete leaves. This change is called phyllody of bracts, and
is seen in species of Plantago, especially in the variety of
Plantago media, called the rose-plantain in gardens,
where the bracts become leafy and form a rosette round the
flowering axis. Similar changes occur in Plantago major, P.
lanceolata, Ajuga reptans, dandelion, daisy, dahlia and
in umbelliferous plants. The conver-
version of bracts into stamens (staminody of bracts) has
been observed in the case of Abies excelsa. A lengthen-
ing of the axis of the female strobili of Coniferae is not
in frequent occurrence in
Crypomeria japonica, larch (Larix europaea), &c., and this is
usually associated with a leaf-like condition of the bracts,
and sometimes even with the development of leaf-bearing
shoots in place of the scales.

The arrangement of the flowers on the axis,
or the ramifications of the floral axis, is called the
inflorescence. The primary axis of the
inflorescence is sometimes called the rachis;
it branches, whether terminal or lateral,
which form the stalks supporting flowers or clusters of flowers,
are peduncles, and if small branches are given off
by it, they are called pedicels. A flower
having a stalk is called pedunculate or pedicel-
late; one having no stalk is sessile. In describing a branching
infloroscence, it is common to speak of the rachis as the primary
floral axis, its branches as the secondary floral axes, their divi-
sions as the tertiary floral axes, and so on; thus avoiding any
confusion that might arise from the use of the terms rachis, ped-
uncle and pedicel.

The peduncle is simple, bearing a single flower, as in primrose;
or branched, as in London-pride. It
is sometimes succulent, as in the cashew, in which it forms
the large coloured expansion supporting the nut; spiral, as in
Cyclamen and Viola; or spiny, as in Alysium spinosum. When the peduncle proceeds
from radical leaves, that is, from an axis which is so shortened
as to bring the leaves close together in the form of a cluster, as
in the primrose, auricula or hyacinth, it is termed a scape.
The floral axis may be shortened, assuming a flattened, convex
or concave form, and bearing numerous flowers, as in the arti-
choke, daisy and fig (fig. 6). The floral axis sometimes appears as
if formed by several peduncles united together, constituting a
fasciated axis, as in the cockscomb, in which the flowers form
a peculiar crest at the apex of the flattened peduncles. Adhe-
sions occasionally take place between the peduncle and the
bracts or leaves of the plant, as
in the lime-tree (fig. 7). The
adhesion of the peduncles to the
stem accounts for the extra-
axillary position of flowers, as
in many Solanaceae. When this
union extends for a considerable
length along the stem, several
leaves may be interposed be-
tween the part where the ped-
uncle becomes free and the leaf
whence it originated, and it may
be difficult to trace the connec-
tion. The peduncle occasionally
becomes abortive, and in place
of bearing a flower, is trans-
formed into a tendril; at other
times it is hollowed at the apex,
as apparently to form the lower
part of the outer whorl of
floral leaves as in Eschscholtzia.
The termination of the peduncle,
or the part on which the whorls
of the flower are arranged, is
called the thalamus, torus or rec-
bipetal.

There are two distinct types of
infloroscence—one in which the
flowers arise as lateral shoots
from a primary axis, which goes on
elongating, and the lateral
shoots never exceed in their
development the length of the
primary axis beyond their point of origin. The flowers
are thus always axillary.

Exceptions, such as in cruciferous
plants, are due to the non-appearance
of the bracts. In the other
type the primary axis terminates

in a single flower, but lateral axes are
given off from the axis of the bracts,
which again repeat the primary axis;
the development of each lateral axis
is stronger than that of the primary
axis beyond its point of origin. The
flowers produced in this infloroscence
are thus terminal. The first kind
of infloroscence is indefinite,
indeterminate. Here the axis is either elongated,
producing flower-buds as it grows, the lower expanding first (fig. 8), or it is shortened and depressed, and the outer flowers expand first (fig. 9). The expansion of the flowers is thus centripetal, that is, from base to apex, or from circumference to centre.

The second kind of inflorescence is determinate, definite or terminal. In this the axis is either elongated and ends in a solitary flower, which thus terminates the axis, and if other flowers are produced, they belong to secondary axes farther from the centre; or the axis is shortened and flattened, producing a number of separate floral axes, the central one expanding first, while the others are developed in succession farther from the centre. The expansion of the flowers is in this case centripetal, that is, from apex to base, or from centre to circumference. It is illustrated in fig. 10, Ranunculus bulbosus; a’ is the primary axis swollen at the base in a bulb-like manner b, and with roots proceeding from it. From the leaves which are radical proceeds the axis ending in a solitary terminal flower f’. About the middle of this axis there is a leaf or bract, from which a secondary floral axis is produced ending in a single flower f”, less advanced than the flower f’. This secondary axis bears a leaf also, from which a tertiary floral axis a”’ is produced, bearing an unexpanded solitary flower f”’. From this tertiary axis a fourth is in progress of formation. Here f’ is the termination of the primary axis, and this flower expands first, while the other flowers are developed centrifugally on separate axes.

A third series of inflorescences, termed mixed, may be recognised. In them the primary axis has an arrangement belonging to the opposite type from that of the branches, or vice versa. According to the mode and degree of development of the lateral shoots and also of the bracts, various forms of both inflorescences result.

Amongst indefinite forms the simplest occurs when a lateral shoot produced in the axil of a large single foliage leaf of the plant ends in a single flower, the axis of the plant elongating beyond, as in Veronica hederifolia, Vinca minor and Lychnis nemorum. The flower in this case is solitary, and the ordinary leaves become bracts by producing flower-buds in place of leaf-buds; their number, like that of the leaves of this main axis, is indefinite, varying with the vigour of the plant. Usually, however, the floral axis, arising from a more or less altered leaf or bract, instead of ending in a solitary flower, is prolonged, and bears numerous bracteoles, from which smaller pedicels are produced, and those again in their turn may be branched in a similar way. Thus the flowers are arranged in groups, and frequently very complicated forms of inflorescence result. When the primary peduncle or floral axis, as in fig. 8, is elongated, and gives off pedicels, ending in single flowers, a raceme is produced, as in currant, hyacinth and barberry. If the secondary floral axis give rise to tertiary ones, the raceme is branching, and forms a panicle, as in Yucca gloriosa. If in a raceme the lower flower-stalks are developed more strongly than the upper, and thus all the flowers are nearly on a level, a corymb is formed, which may be simple, as in fig. 11, where the primary axis a’ gives off secondary axes a”, a’”, which end in single flowers; or branching, where the secondary axes again subdivide. If the pedicels are very short or wanting, so that the flowers are sessile, a spike is produced, as in Plantago and vervain (Verbena officinalis) (fig. 12). If the spike bears unisexual flowers, as in willow or hazel (fig. 13), it is an amentum or catkin, hence such trees are called amelanchiferous; at other times it becomes succulent, bearing numerous flowers, surrounded by a sheathing bract or spathe, and then it constitutes a spadix, which may be simple, as in Arum maculatum (fig. 14), or branching as in palms. A spike bearing female flowers only, and covered with scales, is a strobilus, as in the hop. In grasses

there are usually numerous sessile flowers arranged in small spikes, called locustae or spikelets, which are either set closely along a central axis, or produced on secondary axes formed by the branching of the central one; to the latter form the term panicle is applied.

If the primary axis, in place of being elongated, is contracted, it gives rise to other forms of indefinite inflorescence. When the axis is so shortened that the secondary axes arise from a common point, and spread out as radii of nearly equal length, each ending in a single flower or dividing again in a similar radiating manner,

an umbel is produced, as in fig. 15. From the primary floral axis a the secondary axes come off in a radiating or umbrella-like manner, and end in small umbels b, which are called partial umbels or umbellules. This inflorescence is seen in hemlock and other allied plants, which are hence called umbelliferous. If there are numerous flowers on a flattened, convex or slightly concave receptacle, having very short pedicels or none, a

Fig. 15.—Compound umbel of Common Dill (Anthemis graveolens), having a primary umbel a, and secondary umbels b, without either involucres or involucels.
capitulum (head) is formed, as in dandelion, daisy and other composite plants (fig. 2), also in scabious (fig. 9) and teasel. In the American button-bush the heads are globular, in some species of teasel elliptical, while in scabious and in composite plants, as sunflower, dandelion, thistle, centaury and marigold, they are somewhat hemispherical, with a flattened, slightly hollowed, or convex disk. If the margins of such a receptacle be developed upwards, the centre not developing, a concave receptacle is formed, which may partially or completely enclose a number of flowers that are generally unsexual. This gives rise to the peculiar inflorescence of *Dorstenia*, or to that of the fig (fig. 6), where the flowers are placed on the inner surface of the hollow receptacle, and are provided with bracteoles. This inflorescence has been called a *hypenthodium*.

Lastly, we have what are called *compound indefinite* inflorescences. In these the lateral shoots, developed centrifugally upon the primary axis, bear numerous bracteoles, from which floral shoots arise which may have a centripetal arrangement similar to that on the mother shoot, or it may be different. Thus we may have a group of racemes, arranged in a racemose manner on a common axis, forming a raceme of racemes or compound raceme, as in *Asphodelus*. In the same way we may have compound umbels, as in hemlock and most Umbelliferae (fig. 15), a compound spike, as in rye-grass, a compound spadix, as in some palms, and a compound capitulum, as in the hen-and-chickens daisy. Again, there may be a raceme of capitula, that is, a group of capitula disposed in a racemose manner, as in *Petasites*, a raceme of umbels, as in ivy, and so on, all the forms of inflorescence being indefinite in disposition. In *Eryngium* the shortening of the pedicles changes an umbel into a capitulum.

The simplest form of the definite type of the inflorescence is seen in *Anemone nemorosa* and in gentianella (*Gentiana acaulis*), where the axis terminates in a single flower, no other flowers being produced upon the plant. This is a solitary terminal inflorescence. If other flowers were produced, they would arise as lateral shoots from the bracts below the first-formed flower. The general name of *cyms* is applied to the arrangement of a group of flowers in a definite inflorescence. A *cymsese* inflorescence is one where the primary floral axis before terminating in a flower gives off one or more lateral uniflorous axes which repeat the process—the development being only limited by the vigour of the plant. The floral axes are thus centrifugally developed. The cymsese, according to its development, has been characterized as biparous or uniparous. In fig. 16 the biparous cymsese is represented in the flowering branch of *Cerastium*. Here the primary axis ends in a flower, which has passed into the state of fruit. At its base two leaves are produced, in each of which arise secondary axes *t*, ending in single flowers, and at the base of these axes a pair of opposite leaves is produced, giving rise to tertiary axes *t*, ending in single flowers, and so on. The term *dichasium* has also been applied to this form of cymsese.

In the natural order Carophyllaceae (pink family) the dichasial form of inflorescence is very general. In some members of the order, as *Dianthus barbatus*, *D. carthusianorum*, etc., in which the peduncles are short, and the flowers closely approximated, with a centrifugal expansion, the inflorescence has the form of a contracted dichasium, and receives the name of *fascicle*. When the axes become very much shortened, the arrangement is more complicated in appearance, and the nature of the inflorescence can only be recognized by the order of opening of the flowers. In Labiate plants, as the dead-nettle (*Lamium*), the flowers are produced in the axil of each of the foliage leaves of the plant, and they appear as if arranged in a simple whorl of flowers. But on examination it is found that there is a central flower expanding first, and from its axis two secondary axes spring bearing solitary flowers; the expansion is thus centrifugal. The inflorescence is therefore a contracted dichasium, the flowers being sessile, or nearly so, and the clusters are called *verticillasters* (fig. 17). Sometimes, especially towards the summit of a dichasium, owing to the exhaustion of the growing power of the plant, only one of the bracts gives origin to a new axis, the other remaining empty; thus the inflorescence becomes unilatral, and further development is arrested. In addition to the dichasial form there are others where more than two lateral axes are produced from the primary floral axis, each of which in turn produces numerous axes. To this form the terms *trichasial* and *polychassial cyme* have been applied; but these are now usually designated *cymsese umbels*. They are well seen in some species of *Euphorbia*. Another term, *anthela*, has been used to distinguish such forms as occur in several species of *Luzula* and *Juncus*, where numerous lateral axes arising from the primary axis grow very strongly and develop in an irregular manner.

In the uniparous cyme a number of floral axes are successively developed one from the other, but the axis of each successive generation, instead of producing a pair of bracts, produces only one. The basal portion of the consecutive axes may become much thickened and arranged more or less in a straight line,

![Fig. 16.—Cymose inflorescence (dichasium) of Cerastium collinum, 4-5<sup>1</sup>, successive axes. (After Duchartre.)](https://example.com/f16.png)
FLOWER

and thus collectively form an apparent or false axis or symposium, and the inflorescence thus simulates a raceme. In the true raceme, however, we find only a single axis, producing in succession a series of bracts, from which the floral peduncles arise as lateral shoots, and thus each flower is on the same side of the floral axis as the bract in the axil of which it is developed; but in the uniparous cyme the flower of each of these axes, the basal portions of which unite to form the false axis, is situated on the opposite side of the axis to the bract from which it apparently arises (fig. 18). The bract is not, however, the one from which the axis terminating in the flower arises, but is a bract produced upon it, and gives origin in its axil to a new axis, the basal portion

In the helicoid cyme there is also a false axis formed by the basal portion of the separate axes, but the flowers are not placed in a double row, but in a single row, and form a spiral or helix round the false axis. In Streplocarpus, as represented in fig. 18, the axis a1 ends in a flower (cut off in the figure) and bears a leaf. From the axil of this leaf, that is, between it and the primary axis a1, arises a secondary axis a2, ending in a flower f2, and producing a leaf about the middle. From the axil of this leaf a tertiary floral axis a3, ending in a flower f3, takes origin. In this case the axes are not arranged in two rows along one side of the false axis, but are placed at regular intervals, so as to form an elongated spiral round it.

Compound definite inflorescences are by no means common, but in Streptocarpus polygonus and in some arctotid flowers, we probably have examples. Here there are scorpionoid cymes of pairs of flowers, each pair consisting of an older and a younger flower.

Forms of inflorescence occur, in which both the definite and indefinite types are represented—mixed inflorescences. Thus in composite plants, such as hawkweeds (Hieracium) and ragworts (Senecio, fig. 21), the heads of flowers, taken as a whole, are developed centrifugally, the terminal head first, while the florets, or small flowers on the receptacle, open centripetally, those at the circumference first. So also in Labiatae, such as dead-nettle (Lamium), the different whorls of inflorescence are developed centripetally, while the florets of the verticillaster are centrifugal. This mixed character presents difficulties in such cases as Labiatae, where the leaves, in place of retaining their ordinary form, become bracts, and thus might lead to the supposition of the whole series of flowers being one inflorescence. In such cases the cymes are described as spiky, racemose, or panicked, according to circumstances. In Saxifraga umbrosa (London-pride) and in the horse-chestnut (Aesculus), a capitulum of contracted scorpionoid cymes (often called a glomerulus); in laurustinus, a compound umbel of dichasia cymes; a scorpionoid cyme of capitula in Veronica scorpionides. The so-called catkins of the birch are, in reality, spikes of contracted dichasia cymes. In the bell-flower (Campanula) there is a racemose uniparous cyme. In the privet (Ligustrum vulgare) there are numerous racemes of dichasia arranged in a racemose manner along an axis; the whole inflorescence thus has an appearance not unlike a bunch of grapes, and has been called a thyrsus.

The flower consists of the floral axis bearing the sporophylls (stamens and carpels), usually with certain protective envelopes.

The axis is usually very much contracted, no inter-nodes being developed, and the portion bearing the floral leaves, termed the thalamus or torus, frequently expands into a conical, flattened or broad torus, which is the basis upon which the parts, though rarely, are developed and is elongated. Upon this torus the parts of the flower are arranged in a crowded manner, usually forming a series of verticils, the parts of which alternate; but they are sometimes arranged spirally especially if the floral axis is elongated. In a typical flower, as in fig. 22, we recognize four distinct whorls of leaves: an outer whorl, the calyx of sepals; within it, another whorl, the parts alternating with those of the outer whorl, the corolla of petals; next a whorl of parts alternating with the parts of the corolla, the anther or stamens; and in the centre the gynoecium of carpels.

Fig. 23 is a diagrammatic representation of the arrangement of the parts of a flower, as it is known as a floral diagram. The flower is supposed to be cut transversely, and the parts of each whorl are distinguished by a different symbol. Of these whorls the two internal, forming the sporophylls, constitute the essential organs of reproduction; the two outer whorls are the protective coverings or floral envelopes. The sepals are generally of a greenish colour, their function is mainly protective, shielding the more delicate internal organs before the flower opens. The petals are usually showy, and normally alternate with the sepals. Sometimes, as in monocotyledons, the calyx and corolla are similar; in such cases the term pistil, or perigon, is applied. Thus, in the tulip, among other plants, in place of the several petals, there is an outer whorl (calyx), of three parts, and an inner (corolla), of a similar number, alternating with them. When the parts of the calyx are in appearance like petals they are said to be petaloid, as in Lilacaceae. In some cases the petals have the appearance of sepals, and are then sepaloïd, as in Juncaceae. In plants, as Nymphea alba, where a spiral arrangement of the floral leaves occurs, it is not easy to say where the calyx ends and the corolla begins; as these two whorls pass insensibly into each other. When both calyx and corolla are present, the plants are dichlamydeous; when one only is present, the flower is termed monochlamydeous or petaloid, having no petals (fig. 24). Sometimes both are absent, when the flower is achlamydeous, or naked, as in willow. The outermost series of the essential organs, collectively termed the androecium, is composed of the microsporophylls known as the stamine leaves or stamens. In their most differentiated form each consists of a stalk, the filament (fig. 25, f), supporting at its summit the anther (a), consisting of the pollen-sacs which contain the powdery pollen (p), the microspores, which is ultimately discharged therefrom. The gynoecium or pistil is the central portion of the flower, terminating the floral axis. It consists of one or more carpels (megasporophylls), either separate (fig. 22, c) or combined (fig. 24). The parts distinguished in the pistil are the ovary portion enclosing the ovules destined to become seeds, and the stigma (g), a portion of loose cellular tissue, the receptive surface on which the pollen is deposited, which is either sessile on the apex of the ovary, as in the poppy, or is separated from it by a prolonged portion called the style (s). The androecium and gynoecium are not present in all flowers. When both are present the flower is hermaphrodite, and in descriptive botany such a flower is indicated by the symbol $\beta$. When only one of those organs is present the flower is unisexual or dioecious, and is either male (stamine), $\delta$, or female (pistillate), $\varphi$. A flower then normally consists of the four series of leaves—calyx, corolla, androecium and gynoecium—and when these are all present the flower is complete. These are usually densely crowded upon the thalamus, but in some instances, after apical growth has ceased in the axis, an elongation of portions of the receptacle by intercalary growth occurs, by which changes in the position of the parts may be brought about. Thus in Lycopus an elongation of the axis betwixt the calyx and the corolla takes place, and in this way they are separated by an interval. Again, in the passion-flower (Passiflora) the stamens are separated from the corolla by an elongated portion of the axis, which has consequently been termed the androecium, and in Passiflora also, fraxinella (fig. 27), Capparidaceae, and some other plants, the ovary is raised upon a distinct stalk termed the gynophore; it is thus separated from the stamens, and is said to be stigmatate. Usually the successive whorls of the flower, disposed from below upwards or from without inwards upon the floral axis, are of the same number of parts, or are a multiple of the same number of parts, those of one whorl alternating with those of the whorls next it. In the more primitive types of flowers the torus is more or less convex, and the series of organs follow in regular succession, culminating in the carpels, in the formation of which the growth of the axis is closed (fig. 28). This arrangement is known as hypogynous, the other series (calyx, corolla and stamens) being beneath (hypo-) the gynoecium. In other cases, the apex of the growing point ceases to develop, and the parts below form a cup around it, from the rim of which the outer members of the flower are developed around (perig-) the carpels, which are formed from the bottom of the cup. This arrangement is known as perigynous (fig. 29). In many cases this is carried farther and a cavity is formed which is roofed over

**Fig. 27.** Calyx and pistil of Praxipellis (Dictamnus Praxipellis). The pistil consists of several carpels, which are elevated on a stalk or gynophore prolonged from the receptacle.
FLOWER

by the carpels, so that the outer members of the flower spring from the edge of the receptacle which is immediately above the ovary (epigynous), hence the term epigyny (fig. 30).

When a flower consists of parts arranged in whorls it is said to be cyclic and if all the whorls have an equal number of parts and are alternate it is eucyclic (figs. 22, 23). In Symmetry of the flower. contrast to the cyclic flowers are those, as in Magnoliaceae, where the parts are in spirals (acyclic). Flowers which are cyclic at one portion and spiral at another, as in many Ranunculaceae, are termed hemicyclic. In spiral flowers the distinction into series is by no means easy, and usually there is a gradual passage from sepaloid through petaloid to staminal parts, as in the water-lily family, Nymphaeaceae (figs. 31, 32), although in some plants there is no such distinction, the parts being all petaloid, as in Trollius. Normally, the parts of successive whorls alternate; but in some cases we find the parts of one whorl opposite or superposed to those of the next whorl. In some cases, as in the vine-family Ampelidaceae, this seems to be the ordinary mode of development, but the superposition of the stamens on the sepals in many plants, as in the pink family, Caryophyllaceae, is due to the suppression or abortion of the whorl of petals, and this idea is borne out by the development, in some plants of the order, of the suppressed whorl. As a rule, whenever we find the parts of one whorl superposed on those of another we may suspect some abnormality.

A flower is said to be symmetrical when each of its whorls consists of an equal number of parts, or when the parts of any one whorl are multiples of that preceding it. Thus, a symmetrical flower may have five sepals, five petals, five stamens and five carpels, or the number of any of these parts may be ten, twenty or some multiple of five. Fig. 23 is a diagram of a symmetrical flower, with five parts in each whorl, alternating with each other. Fig. 33 is a diagram of a symmetrical flower of stone-crop, with five sepals, five alternating petals, ten stamens and five carpels. Here the number of parts in the staminal whorl is double that in the others, and in such a case the additional five parts form a second row alternating with the others. In the staminal whorl especially it is common to find additional rows. Fig. 34 shows a symmetrical flower, with five parts in the three outer rows, and ten divisions in the inner. In this case it is the gynoeceum which has an additional number of parts. Fig. 35 shows a flower of heath, with four divisions of the calyx and corolla, eight stamens in two rows, and four divisions of the pistil. In fig. 36 there are three parts in each whorl; and in fig. 37 there are three divisions of the calyx, corolla and pistil, and six stamens in two rows. In all these cases the flower is symmetrical. In Monocotyledons it is usual for the staminal whorl to be double, it rarely having more than two rows, whilst amongst dicotyledons there are often very numerous rows of stamens. The floral envelopes are usually multiplied. Flowers in which the number of parts in each whorl is the same, are isomerous (of equal number); when the number in some of the whorls is different, the flower is anisomerous (of unequal number). The pistillate whorl is very liable to changes. It frequently happens that when it is fully formed, the number of its parts is not in conformity with that of the other whorls. In such circumstances, however, a flower has been called symmetrical, provided the parts of the other whorls are normal,—the permanent state of the pistil not being taken into account in determining symmetry. Thus fig. 38 shows a pentamous symmetrical flower, with dimerous pistil. Symmetry, then, in botanical language, has reference to a certain definite numerical relation of parts. A flower in which the parts are arranged in twos is called dimerous: when the parts of the whorls are three, four or five, the flower is trimerous, tetramerous or pentamerous, respectively. The symmetry which is most commonly met with is trimerous and pentamerous— the former occurring generally among monocotyledons, the latter among dicotyledons. Dimerous and tetramerous symmetry occur also among dicotyledons.

The various parts of the flower have a certain definite relation to the axis. Thus, in auxiliary tetramerous flowers (fig. 35), one sepal is set on the axis, and is called superior or posterior; another is next the bract, and is inferior or anterior, and the other two are lateral; and certain terms are used to indicate that position. A plane passing through the anterior and posterior sepal and through the floral axis is termed the median plane of the flower; a plane cutting it at right angles, and passing through the lateral sepals, is the lateral plane; whilst the planes which bisect the

FIGS. 31 AND 32.—White Water Lily. Fig. 31, flower; fig. 32, successive stages, of the transition from petals to stamens. (After Wossidlo.)
angles formed by the lateral and median planes are the diagonal planes, and in these flowers the petals which alternate with the sepals are cut by the diagonal planes.

In a regular one, each petal may be superior, as in the calyx of Rosaceae and Labiatae; or it may be inferior, as in the calyx of Leguminosae (fig. 39)—the reverse, by the law of alternation, being the case with the petals. Thus, in the blossom of the pea (figs. 39, 40), the odd petal ( vexillum) is superior, while the odd sepal is inferior. In the order Scrophulariaceae, one of the two carpels is posterior and the other anterior, whilst in Convolvulaceae the carpels are arranged laterally. Sometimes the twisting of a part makes a change in the position of other parts, as in Orchids, where the twisting of the ovary changes the position of the labellum.

When the different members of each whorl are like in size and shape, the flower is said to be regular; while differences in the size and shape of the parts of a whorl make the flower irregular, as in the papilionaceous flower, represented in fig. 39. When a flower can be divided by a single plane into two exactly similar parts, then it is said to be zygomorphic. Such flowers as Papilionaceae, Labiatae, are examples. In contrast with this are polysymmetrical or actinomorphic flowers, which have a radial symmetry and can be divided by several planes into several exactly similar portions; such are all regular, symmetrical flowers. When the parts of any whorl are not equal to or some multiple of the others, then the flower is asymmetrical. This want of symmetry may be brought about in various ways. Alteration in the symmetrical arrangement as well as in the completeness and regularity of flowers has been traced to suppression or the non-development of parts, degeneration or imperfect formation, cohesion or union of parts of the same whorl, adhesion or union of the parts of different whorls, multiplication of parts, and deduplication (sometimes called choris) or splitting of parts.

By suppression or non-appearence of a part at the place where it ought to appear if the structure was normal, the symmetry or completeness of the flower is disturbed. This suppression when confined to the parts of certain verticils makes the flower asymmetrical. Thus, in many Caryophyllaceae, as Polygonum and Holosteum, while the calyx and corolla are pentamorous, there are only three or four stamens and three carpels; in Impatiens Noli-me-tangere the calyx is composed of three parts, while the other verticils have five; in labiate flowers there are five parts of the calyx and corolla, and only four stamens; and in Tropaeolum pensylhium there are five sepals, two petals, eight stamens, and three carpels. In all these cases the original symmetry is traced to the suppression of certain parts. In the last-mentioned plant the normal number is five, hence it is said that there are three petals suppressed, as shown by the position of the two remaining ones; there are two rows of stamens, in each of which one is wanting; and there are two carpels suppressed. In many instances the parts which are afterwards suppressed can be seen in the early stages of growth, and occasionally some vestiges of them remain in the fully developed flower. By the suppression of the verticil of the stamens, or of the carpels, flowers become unisexual or dioecious, and by the suppression of one or both of the floral envelopes, monoachlamydeous and achlamydeous flowers are produced. The suppression of parts of the flower may be carried so far that at last a flower consists of only one part of one whorl. In the Euphorbiaceae we have an excellent example of the gradual suppression of parts, there from an apetalous, trimerous, staminal flower, we pass to one where one of the stamens is suppressed, and then to forms where two of them are wanting. We next have flowers in which the calyx is suppressed, and its place occupied by one, two or three bracts (so that the flower is, properly speaking, achlamydeous), and only one or two stamens are produced. And finally, we find flowers consisting of a single stamen with a bract. There is thus traced a degradation, as it is called, from a flower with three stamens and three divisions of the calyx, to one with a single bract and a single stamen.

Degeneration, or the transformation of parts, often gives rise either to an apparent want of symmetry or to irregularity in form. In unisexual flowers it is not uncommon to find vestiges of the undeveloped stamens in the form of filiform bodies or scales. In double flowers transformations of the stamens and pistils take place, so that they appear as petals. In Conna, what are called petals are in reality metamorphosed stamens. In the capitula of Compositae we sometimes find the florets converted into green leaves. The limb of the calyx may appear as a rim, as in some Umbellifereae; or as pappus, in Compositae, and Valeriana. In Scrophularia the fifth stamen appears as a scale-like body; in other Scrophulariaceae, as in Penstemon, it assumes the form of a filament, with hairs at its apex in place of an anther.

 Cohesion, or the union of parts of the same whorl, and adhesion, or the growing together of parts of different whorls, are causes of change both as regards form and symmetry. Thus in Cucubita the stamens are originally five in number, but subsequently some come, so that three stamens only are seen in the mature flower. Adhesion is well seen in the gynostemium of orchids, where the stamens and stigmas adhere. In Capparidaceae the calyx and petals occupy their usual position, but the axis is prolonged in the form of a gynophore, to which the stamens are united.

 Multiplication, or an increase of the number of parts, gives rise to changes. We have already alluded to the interposition of new members in a whorl. This takes place chiefly in the staminal whorl, but usually the additional parts produced form a symmetrical whorl with the others. In some instances, however, this is not the case. Thus in the horse-chestnut there is an interposition of two stamens, and thus seven stamens are formed in the flower, which is asymmetrical.

Parts of the flower are often increased by a process of deduplication, or choris, i.e., the splitting of a part so that two or more parts are formed out of what was originally one. Thus in Crucifers plants the staminal whorl consists of four long stamens and two short ones (tetradynamous). The symmetry in the flower is evidently dimerous, and the abnormality in the androecium, where the four long stamens are opposite the posterior sepals, takes place by a splitting, at a very early stage of development, of a single outgrowth into two. Many cases of what was considered choris are in reality due to the development of stipules from the staminal leaf. Thus in Dicentra and Corydalis there are six stamens in two bundles; the central one of each bundle alone is perfect, the lateral ones have each only half an anther, and are really stipules formed from the staminal leaf. Branching of stamens also produces apparent want of symmetry; thus, in the so-called polyadephous stamens of Hypericaceae there are really only five stamens which give off numerous branches, but the basal portion remaining short, the branches have the appearance of separate stamens, and the flower thus seems asymmetrical.

 Cultivation has a great effect in causing changes in the various parts of plants. Many alterations in form, size, number and adhesion of parts are due to the art of the horticulturist. The changes in the colour and forms of flowers thus produced are entirely different. In the dark-husked cereals, for example, they are made to assume many glowing colours. In pelargonium the flowers have been rendered larger and more showy; and such is
also the case with the Ranunculus, the auricula and the carnation. Some flowers, with spurred petals in their usual state, as columbines, are changed so that the spurs disappear; and others, as Lomatium, in which one petal only is usually spurred, are altered so as to have all the petals spurred, and to present what are called pelorin varieties.

As a convenient method of expressing the arrangement of the parts of the flower, floral formulae have been devised. Several modes of expression are employed. The following is a very simple mode which has been proposed:—The several whorls are represented by the letters S (sepals), P (petals), St (stamens), C (carpels), and a figure marked after each indicates the number of parts in that whorl. Thus the formula S3P3St3C means that

The flower is perfect, and has pentamerosy symmetry, the whorls being isomeros.

Such a flower as that of Sedum (fig. 33) would be expressed by the formula S3P3St3C, where Sti3 indicates that the staminal whorl consists of two rows of five parts each. A flower such as the male flower of the nettle (fig. 41) would be expressed S3P3St3C. When no other mark is appended the whorls are supposed to be alternate; but if it is desired to mark the position of the whorls special symbols are employed. Thus, to express the superposition of one whorl upon another, a line is drawn between them, e.g. the symbol S3PS3St3C is the formula of the flower of Primula vulgaris.

The manner in which the parts are arranged in the flower-bud with respect to each other before opening is the aestivation or praefloration. The latter terms are applied to the flower-bud in the same way as vernation is to the leaf-bud, and distinctive names have been given to the different arrangements exhibited, both by the leaves individually and in their relations to each other. As regards each leaf of the flower, it is either spread out, as the sepals in the bud of the lime-tree, or folded upon itself (conduplicate), as in the petals of some species of Lysimachia, or slightly folded inwards or outwards at the edges, as in the

The inrolled petals of clematis and of some herbaceous plants, or rolled up at the edges (involute or revolute), or folded transversely, becoming cramped or corrugated, as in the poppy. When the parts of a whorl are placed in an exact circle, and are applied to each other by their edges only, without overlapping or being folded, thus resembling the valves of a seed-vessel, the aestivation is involute (fig. 42). The edges of each of the parts may be turned either inwards or outwards; in the former case the aestivation is induplicate (fig. 43), in the latter case reduplicate (fig. 44). When the parts of a single whorl are placed in a circle, each of them exhibiting a torsion of its axis, so that by one of its sides it overlaps its neighbour, whilst its side is overlapped in like manner by that standing next to it, the aestivation is twisted or contorted (fig. 45). This arrangement is characteristic of the flower-buds of Malvaceae and Apocynaceae, and it is also seen in Convolvulaceae and Caryophyllaceae. When the flower is opened, the traces of it often disappear, but sometimes, as in Apocynaceae, they remain. Those forms of aestivation are such as occur in cyclic flowers, and they are included under circular aestivation. But in spiral flowers we have a different arrangement; thus the leaves of the calyx of Camelina japonica cover each other partially like tiles on a house. This aestivation is imbricate. At other times, as in the petals of Camelina, the parts envelop each other completely, so as to become convolute.

This is also seen in a transverse section of the calyx of Magnolia grandiflora, where each of the three leaves embraces that within it. When the parts of the whorl are five, as occurs in many dicotyledons, and the imbrication is such that there are two parts external, two internal, and a fifth which partially covers one of the internal parts by its margin, and is in its turn partially covered by one of the external parts, the aestivation is quincuncial (fig. 46). This quincunx is common in the corolla of Rosaceae. In fig. 47 a section is given of the bud of Antirrhinum majus, showing the imbricate spiral arrangement. In this case it will be seen that the part marked 5 has, by a slight change in position, become overlapped by 4. This variety of imbricate aestivation has been termed cocklewise. In fig. 48 the calyx is shown, such as those of the pea (fig. 40), one of the parts, the vexillum, is often large and folded over the others, giving rise to vexillar aestivation (fig. 48), or the carina may perform a similar office, and then the aestivation is carinal, as in the Judas-tree (Cercis silicium). The parts of the several verticils often differ in their mode of aestivation. Thus, in Malvaceae the corolla is contorted and the calyx valvate, or reduplicate; in St John's-wort the calyx is imbricate, and the corolla contorted. In Convolvulaceae, while the corolla is twisted, and has its parts arranged in a circle, the calyx is imbricate, and exhibits a spiral arrangement. In Guasuma the calyx is valvate, and the corolla induplicate. The circular aestivation is generally associated with a regular calyx and corolla, while the spiral aestivations are connected with irregular as well as with regular forms.

The sepals are sometimes free or separate from each other, at other times they are united to a greater or less extent; in the former case, the calyx is polypetalous, in the latter monopetalous or monosepalous. The divisions of the calyx present usually the characters of leaves, and in some cases of monstrosity they are converted into leaf-like organs, as not infrequently happens in primulas. They are usually entire, but occasionally they are cut in various ways, as in the rose; they are rarely stalked. Sepals are generally of a more or less oval, elliptical or oblong form, with their apices either blunt or
acute. In their direction they are erect or reflexed (with their apices downward), spreading outwards (divergent or petaloid), or arched inwards (convex). They are usually of a greenish colour (herbaceous); but sometimes they are coloured or petaloid, as in the fuchsia, tropæolum, globe-flower and pomegranate. Whatever be its colour, the external envelope of the flower is considered as the calyx. The vascular bundles sometimes form a prominent rib, which indicates the middle of the sepal; at other times they form several ribs. The venation is useful as pointing out the number of leaves which constitute a gamosepalous calyx. In a polysepalous calyx the number of the parts is indicated by Greek numerals prefixed; thus, a calyx which has three sepals is trisepalous; one with five sepals is pentasepalous. The sepals occasionally are of different forms and sizes. In Aconite one of them is shaped like a helmet (galeate). In a gamosepalous calyx the sepals are united in various ways, sometimes very slightly, and their number is marked by the divisions at the apex. These divisions either are simple projections in the form of acute or obtuse teeth (fig. 49); or they extend down the calyx as fissures about halfway, the true sepals. In Malvaceae an epicalyx is formed by the bracteoles. Degenerations take place in the calyx, so that it becomes dry, scaly, and glume-like (like the glumes of grasses), as in the rushes (Juncaceae); hairy, as in Compositae; or a mere rim, as in some Umbelliferae and Acanthaceae, and in Madder (Rubia tinctorum, fig. 50), when it is called obsolete or marginal. In Compositae, Dipsacaceae and Valerianaceae the calyx is attached to the pistil, and its limb is developed in the form of hairs called pappus (fig. 51). This pappus is either simple (pileus) or feathery (plumose). In Valeriana the superior calyx is at first an obsolete rim, but as the fruit ripens it is shown to consist of hairs rolled inwards, which expand so as to burst the fruit. The calyx sometimes falls off before the flower expands, as in poppies, and is caducous (fig. 52); or along with the corolla, as in Ranunculus, and is deciduous; or it remains after flowering (persistent) as in Labiateæ, Scrophulariaceae, and Boraginaeæ; or its base only is persistent, as in Douturo Stramonium. In Eschscholziæ and Eucalyptus the sepals remain united at the upper part, and become disarticulated at the base or middle, so as to come off in the form of a lid or funnel. Such a calyx is operculate or calyptrate. The existence or non-existence of an articulation determines the deciduous or persistent nature of the calyx.

The receptacle bearing the calyx is sometimes united to the pistil, and enlarges so as to form a part of the fruit, as in the apple, pear, &c. In these fruits the withered calyx is seen at the apex. Sometimes a persistent calyx increases much after flowering, and encloses the fruit without being incorporated with it, becoming accrescent, as in various species of Physalis (fig. 53); at other times it remains in a withered or marcescent form, as in Driæ; sometimes it becomes inflated or vesicular, as in sea campion (Silenæ maritima).

The corolla is the more or less coloured attractive inner floral envelope; generally the most conspicuous whorl. It is present in the greater number of Dicotyles. Petals differ more from ordinary leaves than sepals do, and are much more nearly allied to the staminal whorl. In some cases, however, they are transformed into leaves, like the calyx, and occasionally leaf-buds are developed in their axil. They are seldom green, although occasionally that colour is met with, as in some species of Coby, Hoya viridiflora, Gonolobus viridiferus and Pent tropis spiralis. As a rule they are highly coloured, the colouring matter being contained in the cell-sap, as in blue or red flowers, or in plastids (chromoplasts), as generally in yellow flowers, or in both forms, as in many orange-coloured or reddish flowers. The attractiveness of the petal is often due wholly or in part to surface markings; thus the cuticle of the petal of a pelargonium, when viewed with a ½ or ⅓-in. object-glass, shows beautiful hexagons, the boundaries of which are ornamented with several infected loops in the sides of the cells.

Petals are generally glabrous or smooth; but, in some instances, hairs are produced on their surface. Peltaline hairs, though sparse and scattered, present occasionally the same arrangement as those which occur on the leaves; thus, in Bombacaceæ they are stellate. Coloured hairs are seen on the petals of Menyanthes, and on the segments of the perianth of Iris. They serve various purposes in the economy of the flower, often closing the way to the honey-secreting part of the flower to small insects, whose visits would be useless for purposes of pollination. Although petals are usually very thin and delicate in their texture, they occasionally become thick and fleshy, as in Stipegia and Raflesia; or dry, as in heaths; or hard and stiff, as in Xylopia. A petal often consists of two portions—the lower narrower, resembling the petiole of a leaf, and called the unguis or claw; the upper broader, like the blade of a leaf, and called the lamina or limb. These petals are seen in the petals of the wallflower (fig. 54). The claw is often wanting, as in the crocosmia (fig. 55) and the poppy, which retains the whole petal. According to the development of veins and the growth of cellular tissue, petals present varieties similar to those of leaves. Thus the margin is either entire or divided into lobes or teeth. These teeth sometimes form a regular fringe round the margin, and the
Amongst regular polypetalous corollas may be noticed the rosaceous corolla (fig. 59), in which there are five spreading petals, having no claws, and arranged as in the rose, strawberry and Potentilla; the Caryophyllaceous corolla, in which there are five petals with long, narrow, tapering claws, as in many of the pink tribe; the cruciform, having four petals, often unguiculate, placed opposite in the form of a cross, as seen in wallflower, and in other plants called cruciferous. Of irregular polypetalous corollas the most marked is the Papilionaceous (fig. 49), in which there are five petals:

-one superior (posterior), situated next to the axis, usually larger than the rest, called the vexillum or standard; two lateral, a, the alae or wings; two inferior (anterior), partially or completely covered by the alae, and often united slightly by their lower margins, so as to form a single keel-like piece, called carina, or keel, which embraces the essential organs. This form of corolla is characteristic of British leguminous plants.

Regular gamopetalous corollas are sometimes campanulate or bell-shaped, as in (Campanula) (fig. 60); infundibuliform or funneld-shaped, when the tube is like an inverted cone, and the limb becomes more expanded at the apex, as in tobacco; hypocrateriform or salver-shaped, when there is a straight tube surmounted by a flat spreading limb, as in primula (fig. 61); tubular, having a long cylindrical tube, appearing continuous with the limb, as in Spigelia and comfrey; rotate or wheel-shaped, when the tube is very short, and the limb flat and spreading, as in forget-me-not, Myosotis (where the divisions of the rotate corolla are very acute, as in Galium, it is sometimes called stellate or star-like); urceolate or urn-shaped, when there is scarcely any limb, and the tube is narrow at both ends, and expanded in the middle, as in bell-heath (Erica cinerea). Some of these forms may become irregular in consequence of certain parts being more developed than others. Thus, in Veronica, the rotate corolla has one division much smaller than the rest, and in foxglove (Digitalis) there is a slightly irregular composit in the corolla. Of irregular gamopetalous corollas there may be mentioned the labiate or lipped (fig. 62), having two divisions of the limb in the form of lips (the upper one, u, composed usually of two united petals, and the lower, l, of three), separated by a gap.

In such cases the tube varies in length, and the parts in their union follow the reverse order of what occurs in the calyx, where two sepals are united in the lower lip and three in the upper. When the upper lip of a labiate corolla is much arched, and the lips separated by a distinct gap, it is called ringent (fig. 62). The labiate corolla characterizes the natural order Labiatae. When the lower lip is pressed against the upper, so as to leave only a chink between them, the corolla is said to be personate, as in snapdragon, and some other Scrophulariaceae. In some corollas the two lips become hollowed out in a remarkable manner, as in calcocarlia, assuming a slipper-like appearance, similar to what occurs in the labellum of some orchids, as Cypripedium. When a tubular corolla is split in such a way as to form a strap-like process on one side with several tooth-like projections at its apex, it becomes ligulate or strap-shaped (fig. 63). This corolla occurs in many composite plants, as in the florets of dandelion, daisy and chicory. The number of divisions at the apex indicates the number of united petals, some of which, however, may be
abortsive. Occasionally some of the petals become more united than others, and then the corolla assumes a bilabiate or two-lipped form, as seen in the division of Compositae called Labiatae.

Petals are sometimes suppressed, and sometimes the whole corolla is absent. In *Amorpha* and *Alfedia* the corolla is reduced to a single petal, and in some other Leguminous plants it is entirely wanting. In the natural order Ranunculaceae, some genera, such as *Ranunculus*, globe-flower and pannon, have both calyx and corolla, while others, such as *clamatis*, *anemone* and *Caltha*, have only a coloured calyx. Flowers become double by the multiplication of the parts of the corolline whorl; this arises in general from a metamorphosis of the stamens.

Stigma structures occur on the petals of some flowers, which received in former days the name of *nectaries*. The term nectary was very vaguely applied by Linnaeus to any part of the flower which presented an unusual aspect, as the crown (corona) of *narcissus*, the fringes of the Passion-flower, &c. If the name is retained it ought properly to include only those parts which secrete a honey-like substance, as the glandular depression at the base of the perianth of the frillitary, or on the petal of *Ranunculus* (fig. 55), or on the stamens of Rutaceae. The honey secreted by flowers attracts insects, which, by conveying the pollen to the stigma, effect fertilization. The horn-like nectaries under the calyx-sepals of *aconite* (fig. 58) are modified petals, so also are the tubular nectaries of *hellobore* (fig. 56). Other modifications of some part of the flower, especially of the corolla and stamens, are produced either by degeneration or outgrowth, or by chorisis, or deduplication. Of this nature are the scales on the petals in *Lychnis*, *Silene* and *Cynoglossum*, which are formed in the same way as the lilies of grasses. In other cases, as in *Samolus*, the scales are alternate with the petals, and may represent altered stamens. In *Narcissus* the appendages are united to form a crown, consisting of a membrane similar to that which unites the stamens in *Paeonias*. It is sometimes difficult to say whether these structures are to be referred to the corolline or to the staminal row.

Petals are attached to the axis usually by a narrow base. When this attachment takes place by an articulation, the petals fall off either immediately after expansion (caducous) or after fertilization (deciduous). A corolla which is continuous with the axis and not articulated to it, as in *campanula* and heaths, may be persistent, and remain in a withered or marcescent state while the fruit is ripening. A gamopetalous corolla falls off in one piece; but sometimes the base of the corolla remains persistent, as in *Rhinanthus* and *Orobanchus*.

The stamens and the pistil are sometimes spoken of as the essential organs of the flower, as the presence of both is required in order that perfect seed may be produced. As with few exceptions the stamen represents a leaf, it is called a *stamen*. Flower structures developed to bear the pollen or microspores, it is spoken of in comparative morphology as a microsporophyll; similarly the carpels which make up the pistil are the megasporophylls (see Angiosperms). *Heraphrodite* or *bisexual* flowers are those in which both these organs are found; *unisexual* or *dichious* are those in which only one of these organs appears,—those having stamens only being *stamiferous* or "male," those having the pistil only, *pistilliferous* or "female." But even in plants with hermaphrodite flowers self-fertilization is often provided against by the structure of the parts or by the period of ripening of the organs. For instance, in *Primula* and *Linum* some flowers have long stamens and a pistil with a short style, the others having short stamens and a pistil with a long style. The former occur in the so-called thrum-eyed primroses (fig. 61), the latter in the "pin-eyed." Such plants are called *dimorphic*.

Other plants are *triclinous*, as *Lycorhrymum*, and proper fertilization is only effected by combination of parts of equal length. In some plants the stamens are perfect before the pistil; these are called *protandrous*, as in *Ranunculus repens*, *Silene maritima*, *Zea Mays*. In other plants, but more rarely, the pistil is perfect before the stamens, as in Potentilla argentea, *Plantago major*, *Coix Lachryma*, and they are termed *proterogynous*. Plants in which proterandry or proterogyny occurs are called *dichogamous*. When in the same plant there are unisexual flowers, both male and female, the plant is said to be *perfect*, as in the hazel and castor-oil plant. When the male and female flowers of a species are found on separate plants, the term *diocious* is applied, as in *Mercurialis* and hemp; and when a species has male, female and hermaphrodite flowers on the same or different plants, as in *Paritaria*, it is *polygamous*.

The stamens arise from the thalamus or torus within the petals, with which they generally alternate, forming one or more whorls, which collectively constitute the *androecium*. *Stamens*. Their normal position is below the pistil, and when they are so placed (fig. 64, a) upon the thalamus they are *hypo-gynous*. Sometimes they become adherent to the petals, or are *epipetalous*, and the insertion of both is looked upon as similar, so that they are still hypogynous, provided they are independent of the calyx and the pistil. In other cases they are *perigynous* or *epigynous* (fig. 65). Numerous intermediate forms occur, especially amongst Saxifragaceae, where the parts are *half superior* or *half inferior*. Where the stamens become adherent to the pistil so as to form a column, the flowers are said to be *gynandrous*, as in *Aristolochia* (fig. 66). These arrangements of parts are of great importance in classification. The stamens vary in number from one to many hundreds. In acyclic flowers there is often a gradual transition from *petals* to *stamens*, as in the *white water-lily* (fig. 31). When flowers become double by cultivation, the stamens are converted into petals, as in the *pigeon camellia*, *rose*, &c. When there is only one whorl the stamens are usually equal in number to the sepals or petals, and are arranged opposite to the former, and alternate with the latter. The flower is then *isostemonous*. When the stamens are not equal in number to the sepals or petals, the flower is *anisostemonous*. When there is more than one whorl of stamens, then the parts of each successive whorl alternate with those of the whorl preceding it. The staminal row is more liable to multiplication of parts than the outer whorls. A flower with a single row of stamens is *monostemonous*. If the stamens are double the sepals or petals as regards number, the flower is *diplostemonous*; if more than double, *polyostemonous*. The additional rows of

**FIG. 61. FIG. 62. FIG. 63.**

**FIG. 61.** Flower of cowslip (Primula veris) cut vertically. s, Sepals; joined to form a gamosepalous calyx, c, corolla consisting of tube and spreading limb; v, stamens springing from the mouth of the tube; p, pistil.

**FIG. 62.** Irregular gamosepalous labiate flower of *Lamium album*. The upper lip is composed of two petals united, the lower lip (i) of three. Between the two lips there is a gap. The throat is the part where the tube and the labiate limb join. From the arching of the upper lip this corolla is called ringent.

**FIG. 63.** Irregular gamosepalous ligulate flower of *Ragwort* (Senecio). It is a tubular flower, split down on one side, with the united petals forming a straplike projection. The lines on the flat portion indicate the divisions of the five petals. From the tubular portion below, the bifid style projects slightly or deduplication. Of this nature are the scales on the petals in *Lychnis*, *Silene* and *Cynoglossum*, which are formed in the same way as the lilies of grasses. In other cases, as in *Samolus*, the scales are alternate with the petals, and may represent altered stamens. In *Narcissus* the appendages are united to form a crown, consisting of a membrane similar to that which unites the stamens in *Paeonias*. It is sometimes difficult to say whether these structures are to be referred to the corolline or to the staminal row.

**FIG. 64.** Flower of *Paeonias peregrina*, in longitudinal section. k, Sepal; e, petal; a, stamens; g, pistil. (j nat. size.)

From Strasburger’s *Lehrbuch der Botanik*, by permission of Gustav Fischer.
stamens may be developed in the usual centripetal (acropletal) order, as in Rhamnaceae; or they may be interposed between the pre-existing ones or be placed outside them, i.e. develop centrifugally (basipetally), as in geranium and oxalis, when the flower is said to be obdiplostemonous. When the stamens are fewer than twenty they are said to be definite; when above twenty, when the anther is definite, and are represented by the symbol $\infty$.

The number of stamens is indicated by the Greek numerals prefixed to the term androus; thus a flower with one stamen is monandrous, with two, three, four, five, six or many stamens, di-, tri-, tetra-, penta-, hexo- or polyandrous, respectively.

The function of the stamen is the development and distribution of the pollen. The stamen usually consists of two parts, a contracted portion, often thread-like, termed the filament (fig. 25 f), and a broader portion, usually of two lobes, termed the anther (a), containing the powdery pollen (p), and supported upon the end of the filament. That portion of the filament in contact with the anther-lobes is termed the connective. If the anther is absent the stamen is abortive, and cannot perform its functions. The anther is developed before the filament, and when the latter is not produced, the anther is sessile, as in the mistletoe.

The filament is usually, as its name imports, filiform or thread-like, and cylindrical, or slightly tapering towards its summit. It is often, however, thickened, compressed and flattened in various ways, becoming petaloid in Conna, Marania, water-lily (fig. 32); subulate or slightly broadened at the base and drawn out into a point like an awl, as in Butomus umbellatus; or clasped, that is, narrow below and broad above, as in Thalictrum.

In some instances, as in Tamarix gallica, Peganum harmala, and Campanula, the base of the filament is much dilated, and ends suddenly in a narrow thread-like portion. In these cases the base may give off lateral stipitate processes, as in Allium and Alyssum calycinum. The filament varies much in length and in firmness. The length sometimes bears a relation to that of the pistil, and to the position of the flower, whether erect or drooping. The filament is usually of sufficient solidity to support the anther in an erect position; but sometimes, as in grasses, and other wind-pollinated flowers, it is very delicate and hair-like, so that the anther is pendulous (fig. 105). The filament is generally continuous from one end to the other, but in some cases it is bent or jointed, becoming geminate; at other times, as in the pellitory, it is spiral. It is colourless, or of different colours. Thus in fuchsia and Poinciana, it is red; in Adonis and Tradescantia virginica, blue; in Oenothera and Ranunculus acris, yellow.

Hairs, scales, teeth or processes of different kinds are some-times developed on the filament. In spiderwort (Tradescantia virginica) the hairs are beautifully coloured, moniliform or necklace-like, and afford good objects for studying rotation of the protoplasm. Filaments are usually articulated to the thalamus or torus, and the stamens fall off after fertilization: but in Campanula and some other plants they are continuous with the torus, and the stamens remain persistent, although in a withered state. Changes are produced in the whorl of stamens by cohesion of the filaments to a greater or less extent, while the anthers remain free; thus, all the filaments of the androecium may unite, forming a tube round the pistil, or a central bundle when the pistil is abortive, the stamens becoming monadelphous, as in Polygonum, Pumaria and Pea; in this case the bundles may be equal or unequal. It frequently happens, especially in Papilionaceous flowers, that out of ten stamens nine are united by their filaments, while one (the posterior one) is free (fig. 68). When there are three or more bundles the stamens are triadephous, as in Hypericum aegypticum, or polyadephous, as in Ricinus communis (castor-oil). In some cases, as in Papilionaceous flowers, the stamens cohere, having been originally separate, but in most cases each bundle is produced by the branching of a single stamen. When there are three stamens in a bundle we may conceive the lateral ones as of a stipulary nature. In Lauraceae there are perfect stamens, each having at the base of the filament two abortive stamens or staminodes, which may be analogous to stigmas. Filaments sometimes are adherent to the pistil, forming a column (gynostemium), as in Stylidium, Asclepiadaceae, Rafflesia, and Aristolochiaceae (fig. 66); the flowers are then termed gynandrous.
have a spiral, annular, or reticulated thickening of the wall. The endothecium varies in thickness, generally becoming thinner towards the part where the anther opens, and there disappears entirely. The walls of the cells are frequently absorbed, so that when the anther attains maturity the fibres are alone left, and these by their elasticity assist in discharging the pollen. The anther is developed before the filament, and is always sessile in the first instance, and sometimes continues so. It appears at first as a simple cellular papilla of meristem, upon which an indication of two lobes soon appears. Upon these projections the rudiments of the pollen-sacs are then seen, usually four in number, two on each lobe. In each a differentiation takes place in the layers beneath the epidermis, by which an outer layer of small-celled tissue surrounds an inner portion of large cells. Those central cells are the mother-cells of the pollen, whilst the small-celled layer of tissue external to them becomes the endothecium, the exothecium being formed from the epidermal layer.

In the young state there are usually four pollen-sacs, two for each anther-lobe, and when these remain permanently complete it is a quadrilocular or tetrahedral anther (fig. 70). Sometimes, however, only two cavities remain in the anther, by union of the sacs in each lobe, in which case the anther is said to be bilocular or dithecale. Sometimes the anther has a single cavity, and becomes unilocular, or monothecal, or dimidiate, either by the disappearance of the partition between the two lobes, or by the abortion of one of its lobes, as in Strophelina laeta and Althaea officinalis (hollyhock). Occasionally there are numerous cavities in the anther, as in Viscum and Rafflesia. The form of the anther-lobes varies. They are generally of a more or less oval or elliptical form, or they may be globular, as in Mercurialis annua; at other times linear or clavate, curved, flexuose, or sinuose, as in bronzoy and goird. According to the amount of union of the lobes and the unequal development of different parts of their surface an infinite variety of forms is produced. The anther-lobe is attached to which the filament is attached is the back, the opposite being the face. The division between the lobes is marked on the face of the anther by a groove or furrow, and there is usually on the face a suture, indicating the line of dehiscence. The suture is often towards one side in consequence of the valves being unequal. The stamens may cohere by their anthers, and become syngenious, as in composite flowers, and in lobelia, jasione, &c.

The anther-lobes are united to the connective, which is either continuous with the filament or articulated with it. When the filament is continuous with the connective, and is prolonged so that the anther-lobes appear to be united to it throughout their whole length, and lie in apposition to it and on both sides of it, the anther is said to be adnate or adherent; if the filament ends at the base of the anther, then the latter is innate or erect. In these cases the anther is to a greater or less degree fixed. When, however, the attachment is very narrow, and an articulation exists, the anthers are movable (versatile) and are easily turned by the wind, as in Trionia, grasses (fig. 105), &c., where the filament is attached only to the middle of the connective. The connective may unite the anther-lobes completely or only partially. It is sometimes very short and is reduced to a mere point, so that the lobes are separate or free. At other times it is prolonged upwards beyond the lobes, assuming various forms, as in Alycea and oleander; or it is extended backwards and downwards, as in violet (fig. 71), forming a nectar-secreting spur. In Salvia officinalis the connective is attached to the filament in a horizontal manner, so as to separate the two anther-lobes (fig. 72), one only of which contains pollen, the other being infero-adjacent, unilocular, and sterile. The connective is joined to the filament by a movable joint forming a lever which plays an important part in the pollination-mechanism. In Stachys the connective is expanded laterally, so as to unite the bases of the anther-lobes and bring them into a horizontal line.

The opening or dehiscence of the anthers to discharge their contents takes place either by clefts, by valves, or by pores. When the anthers are erect, the cleft is lengthwise along the line of the suture—longitudinal dehiscence (fig. 25). At other times the slit is horizontal, from the connective to the side, as in Alchemilla arvensis (fig. 73) and in Lemna; transverse dehiscence. When the anther-lobes are rendered horizontal by the enlargement of the connective, then what is really longitudinal dehiscence may appear and appear to be transverse. The cleft does not always proceed the whole length of the anther-lobe at once, but often for a time it extends only partially. In other instances the opening is confined to the base or apex, each locula opening by a single pore, as in Pyrola, Tetratheca juncea, Rhododendron, Vaccinium and Solanum (fig. 74), where there are two, and Paranthema, where there are four; whilst in the mistletoe the anther has numerous pores for the discharge of the pollen. Another mode of dehiscence is the valvular, as in the barberry (fig. 75), where each lobe opens by a valve on the outer side of the suture, separately rolling up from base to apex; in some of the laurel tribe there are two such valves for each lobe, or four in all. In some Gutierrezæ, as Hebradendron cambridgeæ (the Ceylon gamboge plant), the anther opens by a lid separating from the apex (circumstisissile dehiscence).

The anthers dehisce at different periods during the process of flowering; sometimes in the bud, but more commonly when the pistil is fully developed and the flower is expanded. They either dehisce simultaneously or in succession. In the latter case individual stamens may move in succession towards the pistil and discharge their contents, as in Parnassia palustris, or the outer or the inner stamens may first dehisce, following thus a centripetal or centrifugal order. These variations are intimately connected with the arrangements for transference of pollen. The anthers are called introrse when they dehisce by the surface next to the centre of the flower; they are extrorse when they dehisce by the outer surface; when they dehisce by the sides, as in Iris and some grasses, they are laterally dehiscent. Sometimes, from their versatile nature, anthers originally introrse become extrorse, as in the Passion-flower and Oxalis.

The usual colour of anthers is yellow, but they present a great variety in this respect. They are red in the peach, dark purple in the poppy and tulip, orange in Eschscholtzia, &c. The colour and the appearance of the anthers often change after they have discharged their functions.

Stamens occasionally become sterile by the degeneration or non-development of the anthers, when they are known as staminodia, or rudimentary stamens. In Scrophularia the fifth stamen appears in the form of a scale; and in many Pentstemons it is reduced to a filament with hairs or a shrivelled membrane at the apex. In other cases, as in double flowers, the stamens are converted into petals; this is also probably the case with such
plants as Mesembryanthemum, where there is a multiplication of petals in several rows. Sometimes, as in *Canna*, one of the anther-lobes becomes abortive, and a petaloid appendage is produced. Stamens vary in length as regards the corolla. Some are enclosed within the tube of the flower, as in *Cinchona* (included); others are exerted, or extend beyond the flower, as in *Littorella* or *Plantago*. Sometimes the stamens in the early state of the flower project beyond the petals, and in the progress of growth become included, as in *Geranium striatum*. Stamens also vary in their relative lengths. When there is more than one row or whorl in a flower, those on the outside are sometimes longest, as in many Rosaceae; at other times those in the interior are longest, as in *Lubea*. When the stamens are in two rows, those opposite the petals are usually shorter than those which alternate with the petals. It sometimes happens that a single stamen is longer than all the rest. A definite relation, as regards number, sometimes exists between the long and the short stamens. Thus, in some flowers the stamens are *dichotomous*, having only four out of five stamens developed, and the two corresponding to the upper part of the flower longer than the two lateral ones. This occurs in *Labiateae* and *Scroftulariaceae* (fig. 76). Again, in other cases there are six stamens, whereof four long ones are arranged in pairs opposite to each other, and alternate with two isolated short ones (fig. 77), giving rise to *tetradynamous* flowers, as in *Cruciferae*. Stamens, as regards their direction, may be erect, turned inwards, outwards, or to one side. In the last-mentioned case they are called *declinate*, as in *amarillis*, horse-chestnut and *fraxinella*.

The pollen-grains or microspores contained in the anther consist of small cells, which are developed in the large thick-walled mother-cells formed in the interior of the pollen-sacs (microsporangia) of the young anther. These mother-cells are either separated from one another and float in the granular fluid which fills up the cavity of the pollen-sac, or are not so isolated. A division takes place, by which four cells are formed in each, the exact mode of division differing in dicotyledons and monocotyledons. These cells are the pollen-grains. They increase in size and acquire a cell-wall, which becomes differentiated into an outer cuticular layer, or *exine*, and an inner layer, or *intine*. Then the walls of the mother-cells are absorbed, and the pollen-grains float freely in the fluid of the pollen-sacs, which gradually disappears, and the mature grains form a powdery mass within the anther. They then either remain united in fours, or multiples of four, or in some acacias, *Periploma graece* and *Inga anamala*, or separate into individual grains, which by degrees become mature pollen. Occasionally the membrane of the mother-cell is not completely absorbed, and traces of it are detected in a viscid matter surrounding the pollen-grains, as in *Onagraceae*. In orchidaceous plants the pollen-grains are united into masses, or pollinia (fig. 78), by means of viscid matter. In orchids each of the pollen-masses has a prolongation or stalk (*caudicle*) which adheres to a prolongation at the base of the anther (*calix*) by means of a viscid gland (*retinaculum*) which is either naked or covered. The term *clinandrium* is sometimes applied to the part of the column in orchids where the stamens are situated. In some orchids, as *Cypripedium*, the pollen has its ordinary character of separate grains. The number of pollinia varies; thus, in *Orchis* there are usually two, in *Cattleya* four, and in *Laelia* eight. The two pollinia in *Orchis Morio* contain each about 200 secondary smaller masses. These small masses, when bruised, divide into grains which are united in fours. In *Asclepiadaceae* the pollinia are usually united in pairs (fig. 79), belonging to two contiguous anther-lobes—each pollen-mass having a caulicular appendage, ending in a common gland, by means of which they are attached to a process of the stigma. The pollinia are also provided with an appendicular staminal covering (fig. 80). The exine is a firm membrane, which defines the figure of the pollen-grain, and gives colour to it. It is either smooth, or covered with numerous projections (fig. 81), granules, points or crested reticulations. The colour is generally yellow, and the surface is often covered with a viscid or oily matter. The intine is uniform in different kinds of pollen, thin and transparent, and possesses great power of extension. In some aquatics, as *Zostera*, *Zinnichelia*, *Naices*, &c., only one covering exists.

Pollen-grains vary from $\frac{1}{8}$ to $\frac{1}{16}$ of an inch or less in diameter. Their forms are various. The most common form of grain is ellipsoidal, more or less narrow at the extremities, which are called its *poles*, in contradistinction to a line equidistant from the extremities, which is its equator. Pollen-grains are also spherical, cylindrical and curved, as in * Tradescantia virginica*;

![Fig. 80](https://example.com/80)

**Fig. 80.**—Stamen of *Asclepias*, showing filament f, anther a, and appendages p. Enlarged.

In some, as *Hollyhock* (*Althaea rosea*), highly magnified, and possessing great power of extension. In some aquatics, as *Zostera*, *Zinnichelia*, *Naices*, &c., only one covering exists.

Pollen-grains vary from $\frac{1}{8}$ to $\frac{1}{16}$ of an inch or less in diameter. Their forms are various. The most common form of grain is ellipsoidal, more or less narrow at the extremities, which are called its *poles*, in contradistinction to a line equidistant from the extremities, which is its equator. Pollen-grains are also spherical, cylindrical and curved, as in * Tradescantia virginica*;

![Fig. 83](https://example.com/83)

**Fig. 83.**—Male flower of *Polytrichum officinalis*, having four stamens with incurved elastic filaments, and an abortive pistil in the centre. When the perianth (p) expands, the filaments are thrown out with force as at a, so as to scatter the pollen.

Polyhedral in *Dipsacaceae* and *Compositae*; nearly triangular in section in *Proteaceae* and *Onagraceae* (fig. 82). The surface of the pollen-grain is either uniform and homogeneous, or it is marked by folds formed by thinnings of the membrane. There are also rounded portions of the membrane or pores visible in the pollen-grain; these vary in number from one to fifty, and through one
or more of them the pollen-tube is extended in germination of the spore. In Monocotyledons, as in grasses, there is often only one, while in Dicotyledons they number from three upwards; when numerous, the pores are either scattered irregularly, or in a regular order, frequently forming a circle around the central surface. Sometimes at the place where they exist, the outer membrane, in place of being thin and transparent, is separated in the form of a lid, thus becoming operculate, as in the passion-flower and gourd. Within the pollen-grain is the granular protoplasm with some oily particles, and occasionally starch. Before leaving the pollen-sac a division takes place in the pollen-grain into a vegetative cell or cells, from which the tube is developed, and a generative cell, which ultimately divides to form the male cells (see ANGOSPERMS and GYMNOSPERMS).

When the pollen-grains are ripe, the anther dehiscit and the pollen is shed. In order that fertilization may be effected the pollen must be conveyed to the stigma of the pistil. This process, termed pollination (see POLLINATION), is promoted in various ways,—the whole form and structure of the flower having relation to the process. In some plants, as Kalania and Pellitory (fig. 85), the mere elasticity of the filaments is sufficient to effect this; in other plants pollination is effected by the wind, as in most of our forest trees, grasses, &c., and in such cases enormous quantities of pollen are produced. These plants are anemophilous. But the common agents for pollination are insects. To allure and attract them to visit the flower the odoriferous secretions and gay colours are developed, and the position and complicated structure of the parts of the flower are adapted to the perfect performance of the process. It is comparatively rare in hermaphrodite flowers for self-fertilization to occur, and the various forms of dichogamy, dimorphism, and trimorphism are fitted to prevent this.

Under the term disk is included every structure intervening between the stamens and the pistil. It was to such structures that the name of nectary was applied by old authors. It presents great varieties of form, such as a ring, scales, glands, hairs, petaloid appendages, &c., and in the progress of growth it often contains saccharine matter, thus becoming truly nectariferous. The disk is frequently formed by degeneration or transformation of the staminal row. It may consist of processes rising from the torus, alternating with the stamens, abortive whorl; or its parts may be opposite to the stamens. In some flowers, as Japhna Curcas, in which the stamens are not developed, their place is occupied by glandular bodies forming the disk. In Gesneriaceae and Cruciferae the disk consists of tooth-like scales at the base of the stamens. The parts composing the disk sometimes unite and form a glandular ring, as in the orange; or they form a dark-red lamina covering the pistil, as in Paeonia Moutan (fig. 84); or a waxy lining of the whole receptacle, as in Paeonia (Paeonia Moutan), in the rose; or a swelling at the deprivé of its corolla, and top of the ovary, as in Umbelliferae, showing the disk in the form in which the disk is said to be epigynous. The enlarged torus covering the ovary in Nymphaceae (Castalia) and Nelumbium may be regarded as a form of disk.

The pistil or gynoecium occupies the centre or apex of the flower, and is surrounded by the stamens and floral envelopes when these are present. It constitutes the innermost whorl, which on flowering is changed into the fruit and contains the seeds. It consists essentially of two parts, a basal portion forming a chamber, the ovary, containing the ovules attached to a part called the placenta, and an upper receptive portion, the stigma, which is either seated on the ovary (axile), as in the tulip and poppy, or is elevated on a stalk called the style, interposed between the ovary and stigma. The pistil consists of one or more modified leaves, the carpels (or megasporophylls). When a pistil consists of a single carpel it is simple or monocarpellary (fig. 83). When it is composed of several carpels, more or less united, it is compound or polycarpellary (fig. 86). In the first-mentioned case the terms carpel and pistil are synonymous. Each carpel, or its own ovary, style (when present), and stigma, may be regarded as formed by a folded leaf, the upper surface of which is turned inwards towards the axis, and the lower outwards, while from its margins are developed one or more ovules. This comparison is borne out by an examination of the flower of the double-flowering cherry. In it no fruit is produced, and the pistil consists merely of sessile leaves, the limb of each being green and folded, with a narrow prolongation upwards, as if from the midrib, and ending in a thickened portion. In Cyprus the carpels are ordinary leaves, with ovules upon their margin.

A pistil is usually formed by more than one carpel. The carpels may be arranged either at the same or nearly the same height in a verticil, or at different heights in a spiral cycle. When they remain separate and distinct, thus showing at once the composition of the pistil, as in Calitha, Ranunculus, hellebore (fig. 86), and Spiraea, the term apocarpous is applied. Thus, in Sedum (fig. 22) the pistil consists of five verticillate carpels, alternating with the stamens. In Magnolia and Ranunculus (fig. 89) the separate carpels are numerous and are arranged in a spiral cycle upon an elongated axis or receptacle. In the raspberry the carpels are on a conical receptacle; in the strawberry, on a swollen succulent one (fig. 87); and in the rose (fig. 88), on a hollow one. When the carpels are united at the base, arillus and chickweed, the pistil becomes syncarpous. The number of carpels in a pistil is indicated by the Greek numeral. A flower with a simple pistil is monogynous; with two carpels, digynous; with three carpels, trigynous, &c.

The union in a syncarpous pistil is not always complete; it may take place by the ovaries alone, while the styles and stigmas remain free (fig. 90), and in this case, when the ovaries form apparently a single body, the organ receives the name of compound ovary; or the union may take place by the ovaries and styles while the stigmas are dissected; or by the stigmas...
FLOWER

and the summit of the style only. Various intermediate states exist, such as partial union of the ovaries, as in the rue, where they coalesce at their base; and partial union of the styles, as in Malvaceae. The union is usually most complete at the base; but in Labiatae the styles are united throughout their length, and in Apocynaceae and Asclepiadaceae the stigmas only. When the union is incomplete, the number of the parts of a compound pistil may be determined by the number of styles and stigmas; when complete, the external venation, the grooves on the surface, and the internal divisions of the ovary indicate the number.

The ovules are attached to the placenta, which consists of a mass of cellular tissue, through which the nourishing vessels pass to the ovule. The placenta is usually formed on the edges of the carpellar leaf (fig. 91)—marginal. In many cases, however, the placentas are formations from the axis (axile), and are not connected with the carpellar leaves. In marginal placentation the part of the carpel bearing the placenta is the inner or central suture, corresponding to the margin of the folded carpellary leaf, while the outer or dorsal suture corresponds to the midrib of the carpellary leaf. As the placenta is formed on each margin of the carpel it is essentially double. This is seen in cases where the margins of the carpel do not unite, but remain separate, and consequently two placentas are formed in place of one. When the pistil is formed by one carpel the inner margins unite and form usually a common marginal placenta, which may extend along the whole margin of the ovary as far as the base of the style (fig. 91) or may be confined to the base or apex only. When the pistil consists of several separate carpels, or is apocarpous, there are generally separate placentas at each of their margins. In a syncarpous pistil, on the other hand, the carpels are so united that the edges of each of the contiguous ones, by their union, form a septum or dissepiment, and the number of these septa consequently indicates the number of carpels in the compound pistil (fig. 92). When the

diagram of the ovary, then the ovary is unilocular (fig. 93) and the placentas are parietal, as in Viola (fig. 98). In these instances the placentas may be formed at the margin of the united contiguous leaves, so as to appear single, or the margins may not be united, each developing a placenta. Frequently the margins of the carpels, which fold in to the centre, split there into two lamellae, each of which is curved outwards and projects into the

![Fig. 97](image-url)

Diagrammatic section of a compound unilocular ovary, in which there are no indications of partitions. The ovules (o) are attached to a free central placenta, which has no connexion with the walls of the ovary.

![Fig. 98](image-url)

Loculament, dilating at the end into a placenta. This is well seen in Cucurbitaceae (fig. 97), Pyrolo, &c. The carpellary leaves may fold inwards very slightly, or they may be applied in a valvate manner, merely touching at their margins, the placentas then being parietal (fig. 94), and appearing as lines or thickenings along the walls. Cases occur, however, in which the placentas are not connected with the walls of the ovary, and form what is called a free central placenta (fig. 98). This is seen in many of the Caryophyllaceae and Primulaceae (figs. 99,100). In Caryophyllaceae, however, while the placenta is free in the centre, there are often traces found at the base of the ovary of the remains of septa, as if rupture had taken place, and, in rare instances, ovules are found on the margins of the carpels. But in Primulaceae no vestiges of septa or marginal ovules can be perceived at any period of growth; the placenta is always free, and rises in the centre of the ovary. Free central placentation, therefore, has been accounted for in two ways: either by supposing that the placentas in the early state were formed on the margins of

![Fig. 99](image-url)

Pistil of Cerastium hirsutum cut vertically, a. Ovary; p, free central placenta; g, ovules; s, styles.

![Fig. 100](image-url)

The same cut horizontally, and the halves separated so as to show the interior of the cavity of the ovary, a, with the free central placenta p, covered with ovules g.
carpellary leaves, and that in the progress of development these leaves separated from them, leaving the placenta and ovules free in the centre; or by supposing that the placenta are not marginal but axile formations, produced by an elongation of the axis, and the carpels verticillate leaves, united together around the axis. The first of these views applies to Caryophyllaceae, the second to Primulaceae.

Occasionally, divisions take place in ovaries which are not formed by the edges of contiguous carpels. These are called spurious dissepiments. They are often horizontal, as in Cathartocarpus Pistula, where they consist of transverse cellular prolongations from the walls of the ovary, only developed after fertilization, and therefore more properly noticed under fruit. At other times they are vertical, as in Datura, where the ovary, in place of being two-celled, becomes four-celled; in Cruciferae, where the prolongation of the placenta forms a vertical partition; in Astragalus and Thespesia, where the dorsal suture is folded inwards; and in Oxytropis, where the ventral suture is folded inwards.

The ovary is usually of a more or less spherical or curved form, sometimes smooth and uniform on its surface, at other times hairy and grooved. The grooves usually indicate the divisions between the carpels and correspond to the dissepiments. The dorsal suture may be marked by a slight projection or by a superfluous groove. When the ovary is situated on the centre of the receptacle, free from the other whorls, so that its base is above the insertion of the stamens, it is termed superior, as in Lychnis, Primula (fig. 61) and Peony (fig. 64) (see also fig. 28). When the margin of the receptacle is prolonged upwards, carrying with it the floral envelopes and staminal leaves, the basal portion of the ovary being formed by the receptacle, and the carpellary leaves alone closing in the apex, the ovary is inferior, as in pomegranate, aralia (fig. 65), gooseberry and fuchsia (see fig. 30). In some plants, as many Saxifragaceae, there are intermediate forms, in which the term half-inferior is applied to the ovary, whilst the floral whorls are half-superior.

The style proceeds from the summit of the petaloid divisions of the ovary (fig. 102), and is traversed by a narrow canal, in which there are some loose projecting cells, a continuation of the placenta, constituting what is called conducting tissue, which ends in the stigma. This is particularly abundant when the pistil is ready for fertilization. In some cases, owing to more rapid growth of the dorsal sive of the ovary, the style becomes lateral (fig. 101); this may so increase that the style appears to arise from near the base, as in the Chrysobalanus Icaco, when the form of the style is usually cylindrical, more or less filiform and simple; sometimes it is grooved on one side, at other times it is flat, thick, angular, compressed and even petaloid, as in Iris (fig. 103) and Canna. In Goodeniaceae it ends in a cup-like expansion, enclosing the stigma. It sometimes bears hairs, and in the application of the pollen to the stigma, and are called collecting hairs, as in Campanula, and also in some thistle and Compositae. These hairs, during the upward growth of the style, come into contact with the already ripened pollen, and carry it up along with them, ready to be applied by insects to the mature stigma of other flowers. In Vicia and Lobelia the hairs frequently form a tuft below the stigma. The styles of a syncarpous pistil are either separate or united; when separate, they alternate with the sepal; when united completely, the style is said to be simple (fig. 102). The style of a single carpel, or of each carpel of a compound pistil, may also be divided. Each division of the tricarpellary ovary of Jatropha Curcas has a bifurcate or forked style, and the ovary of Emblica officinalis has three styles, each of which is twice forked. The length of the style is determined by the relation which should subsist between the position of the stigma and that of the anthers, so as to allow the proper application of the pollen. The style is deciduous or persists after fertilization.

The stigma is the termination of the conducting tissue of the style, and is usually a viscid matter which detains the pollen, and causes it to germinate. This secreting portion is, strictly speaking, the true stigma, but the name is generally applied to all the divisions of the style on which the stigmatic apparatus is situated. The stigma alternates with the dissepiments of a syncarpous pistil, or, in other words, corresponds with the back of the loculums; but in some cases it would appear that half the stigma of one carpel unites with half that of the contiguous carpel; thus the stigma is opposite the dissepiments, that is, alternates with the loculums, as in the poppy.

The divisions of the stigma mark the number of carpels which compose the pistil. Thus in Campanula a five-cleft stigma indicates five carpels; in Bignoniaceae, Scrophulariaceae and Acanthaceae, the two-lobed or bilamellar stigma indicates a bilocular ovary. Sometimes, however, as in Gramineae, the stigma of a single carpel divides. Its position may be terminal or lateral. In Iris it is situated on a cleft on the back of the petaloid divisions of the ovary (fig. 103). Some stigmas, as those of Mimulus, present sensitive flattened laminae, which close when touched. The stigma presents various forms. It may be globular, as in Mirabilis Jalapa; orbicular, as in Arbutus Andrachne; umbrella-like, as in Sarracenia, where, however, the proper stigmatic surface is beneath the angles of the large expansion of the apex of the style; ovoid, as in fuchsia; hemispherical; polypodral; radiating, as in the poppy (fig. 104), where the true stigmatic rays are attached to a sort of petal or shield-like body, which may represent depressed or flattened styles; cucullate, i.e. covered by a hood, in calabar bean. The lobes of a stigma are flat and pointed as in Mimulus and Bignonia, fleshy and blunt, smooth or granular, or, and feathery, as in many grasses (fig. 105) and other wind-pollinated flowers. In Orchidaceae the stigma is situated on the anterior surface of the column beneath the anther. In Asclepiadaceae the stigmas are united to the face of the anthers, and along with them form a solid mass.

The ovule is attached to the placenta, and destined to become the seed. Ovules are most usually produced on the margins of
the carpellary leaves, but are also formed over the whole surface of the leaf, as in *Butomus*. In other instances they rise
from the floral axis itself, either terminal, as in *Pine-
gonaceae* and *Piperaeaceae*, or lateral, as in *Primulae-
aceae* and *Compositae*. The ovule is usually contained in an ovary,
and all plants in which the ovule is so enclosed are termed *angiospermous*; but in *Coniferae* and *Cycadaceae* it has no proper ovarian covering, and is called naked, these orders being
denominated *gymnospermous*. In *Cycas* the altered leaf, upon
the margin of which the ovule is produced, and the peltate scales,
from which they are pendulous in *Zamia*, are regarded by all
botanists as carpellary leaves. As for the *Coniferae* great dis-
cussion has arisen regarding the morphology of parts in many
genera. The carpellary leaves are sometimes united in such a
way as to leave an opening at the apex of the pistil, so that the
ovules are exposed, as in *mignonea*. In *Leontice thalictroides*
(Blue Cohosh), species of *Ophiopogon*, *Peliosanthes* and *Stateria*,
the ovary ruptures immediately after flowering, and the ovules are
exposed; and in species of *Cuphea* the placenta ultimately
bursts through the ovary and corolla, and becomes erect, bearing the
exposed ovules. The ovule is attached to the placenta either
directly, when it is sessile, or by means of a prolongation *funicle*
(fig. 110, f). This cord sometimes becomes much elongated after
fertilization. The part by which the ovule is attached to the
placenta or cord is its *base or hilum*, the opposite extremity being
its *apex*. The latter is frequently turned round in such a way
as to approach the base. The ovule is sometimes embedded in the
placenta, as in *Hydrora*.

**Figs. 106 and 107.—Successive stages in the development of an ovule. w, Nutellus; i, inner; o, outer integument in section; m, micropyle.**

**Fig. 108.—Orthotropous ovule of *Polygonum* in section, showing the *embryo-sac*, and the *nucleus*.*

**Fig. 109.—Vertical section of the ovule of the Austrian Pine (*Pinus austriaca*), showing the *nucellus*, consisting of delicate cellular tissue containing deep in its substance an *embryo-sac* b. The micropyle m is very wide.**

The ovule appears at first as a small cellular projection from the
placenta. The cells multiply until they assume a more or
less enlarged ovate form constituting what has been called the
*nucellus* (fig. 106, n), or central cellular mass of the ovule. This
nucellus may remain naked, and alone form the ovule, as in
some orders of parasitic plants such as *Balanophoraceae*, Santa-
laceae, &c.; but in most plants it becomes surrounded by certain
coverings or integuments during its development. These appear
first in the form of cellular rings at the base of the nucellus,
which gradually spread over its surface (figs. 106, 107). In some
cases only one covering is formed, especially amongst gamo-
petalous dicotyledons, as in *Compositae*, *Campanulaceae*, also
in walnut, &c. But usually besides the single covering another
is developed subsequently (fig. 106, o), which gradually extends
over that first formed, and ultimately covers it completely,
except at the apex. There are thus two integuments to the
nucellus, an outer and an inner. The integuments do not
completely invest the apex of the nucellus, but an opening termed
the *micropyle* is left. The micropyle indicates the organic apex
of the ovule. A single cell of the nucellus enlarges greatly to
form the *embryo-sac* or megasporangia (fig. 106, s). This embryo-sac
increases in size, gradually supplanting the cellular tissue of the
nucellus until it is surrounded only by a thin layer of it; or it
may actually extend at the apex beyond it, as in *Phaseolus* and
*Altna media*; or it may pass into the micropyle, as in
*Santalum*. In Gymnosperms it usually remains deep in the
nucellus and surrounded by a thick mass of cellular tissue (fig.
109). For an account of the further development of the megas-
spore, and the formation of the egg-cell, from which after fertil-
ization is formed the embryo, see *Gymnosperms* and *Anio-
fers.*

The point where the integuments are united to the base of
the nucellus is called the *chalaza* (figs. 111, 112). This is often
covered, is of a denser texture than the surrounding tissue, and is
traversed by fibrovascular bundles, which pass from the placenta
to nourish the ovule.

When the ovule is so developed that the *chalaza* is at the
hilum (next the placenta), and the micropyle is at the opposite
extremity, there being a short funicle, the ovule is *orthotropous*.
This form is well seen in *Polygonaceae* (fig. 112), *Cistaceae*, and most
*Gymnosperms*. In such an ovule a straight line drawn from the hilum
is carried along the axis of the ovule. Where, by more rapid growth on one side than on the other, the nucellus, together with the integuments, is curved upon itself, so that the micropyle approaches the hilum, and ultimately
is placed close to it, while the chalaza is at the hilum, the ovule is
*camptotropous* (fig. 110). Curved ovules are found in *Cruciferae*,
and *Caryophyllaceae*. The inverted or *anatropous* ovule (fig. 111)
is the commonest form amongst angiosperms. In this ovule the
apex with the micropyle is turned towards the point of attach-
ment of the funicle to the placenta, the chalaza being situated
at the opposite extremity; and the funicle, which runs along the
side usually next the placenta, coalesces with the ovule and
constitutes the *rhaphe* (r), which often forms a ridge. The
anatropous ovule arises from the placenta as a straight or only
slightly curved cellular process, and as it grows, gradually
becomes inverted, curving from the point of origin of the
integuments (cf. figs. 106, 107). As the first integument grows round
it, the amount of inversion increases, and the funicle becomes
adherent to the side of the nucellus. Then if a second integument
is formed it covers all the free part of the ovule, but does not
form on the side to which the raphe is adherent. These may be
taken as the three types of ovule; but there are various inter-
mediate forms, such as semi-*anatropous* and others.

The position of the ovule relative to the ovary varies. When
there is a single ovule, with its axis vertical, it may be attached
to the placenta at the base of the ovary (basal *Placenta*), and is
then erect, as in *Polygonaceae* and *Compositae*; or it may be
inserted a little above the base, on a parietal placenta, with its
apex upwards, and then is ascending, as in *Parietaria*. It may
hang from an apical placenta at the summit of the ovary, its
apex being directed downwards, and is inverted or *pendulous*,
as in *Hippuris vulgaris*; or from a parietal placenta near the
summit, and then is suspended, as in *Daphne mezereum*, *Poly-
galaceae* and *Euphorbiaceae*. Sometimes a long funicle arises
from a basal placenta, reaches the summit of the ovary, and
there bends over suspends the ovule, as in *Armeria* (sea-pink);
at other times the hilum appears to be in the middle, and the
ovule becomes *horizontal*. When there are two ovules in the
same cell, they may be either *collateral*, that is, placed side by
FLOWERS, ARTIFICIAL—FLOYD

The ovule is also undergoing changes which convert it into the seed, and fit it for a protective covering, and a store of nutriment for the embryo. Nor are the effects of fertilization confined to the ovule; they extend to other parts of the plant. The ovary enlarges, and, with the seeds enclosed, constitutes the fruit, frequently incorporated with which are other parts of the flower, as receptacle, calyx, &c. In gymnosperms the pollen-tubes, having penetrated a certain distance down the tissue of the nucellus, are usually arrested in growth for a longer or shorter period, sometimes nearly a year. Fruit and seed are discussed in a separate article—FRUIT.

(A. B. R.)

FLOWERS, ARTIFICIAL. Imitations of natural flowers are sometimes made for scientific purposes (as the collection of Dollier's flowers at Harvard University, which illustrates the flora of the United States), but more often as articles of decoration and ornament. A large variety of materials have been used in their manufacture by different peoples at different times—painted linen and shavings of stained horn by the Egyptians, gold and silver by the Romans, rice-paper by the Chinese, silkworm cocoons in Italy, the plumage of highly colored birds in South America, wax, small tinted shells, &c. At the beginning of the 18th century the French, who originally learnt the art from the Italians, made great advances in the natural reproduction, and towards the end of that century the Paris manufacturers enjoyed a world-wide reputation. About the same time the art was introduced into England by French refugees, and soon afterwards it spread also to America. The industry is now a highly specialized one and comprises a large number of operations performed by separate hands. Four main processes may be distinguished. The first consists of cutting up the various fabrics and materials employed into shapes suitable for forming the leaves, petals, &c.; this may be done by scissors, but more often stamps are employed which will cut through a dozen or more thicknesses at one blow. The veins of the leaves are next impressed by means of a die, and the petals are given their natural rounded forms by gilding irons of various shapes. The next step is to assemble the petals and other parts of the flower, which is built up from the centre outwards; and the fourth is to mount the flower on a stalk formed of brass or iron wire wrapped round with suitably coloured material, and to fasten on the leaves required to complete the spray.

FLOYD, JOHN (1572-1649), English Jesuit, was born in Cambridgeshire in 1572. He entered the Society of Jesus when at Rome in 1592 and is also known as Daniel à Jesu, Hermannus Loemelius, and George White, the names under which he published a score of controversial treatises. He had considerable fame both as a preacher and teacher, and was frequently arrested in England. His last years were spent at Louvain and he died at St Omer on the 13th of September 1649. His brother Edward Floyd was impeached and sentenced by the Commons in 1621 for speaking disparagingly of the elector palatine.

FLOYD, JOHN BUCHANAN (1807-1863), American politician, was born at Blackburg, Virginia, on the 1st of June 1807. He was the son of John Floyd (1770-1837), a representative in Congress from 1817 to 1819 and governor of Virginia from 1830 to 1831. After graduating at South Carolina College in 1826, the son practised law in his native state and at Helena, Arkansas, and in 1839 settled in Washington county, Virginia, which in 1847-1849 and again in 1853 he represented in the state legislature. Meanwhile, from 1849 to 1852, he was governor of Virginia, in which position he recommended to the legislature the enactment of a law laying an import tax on the products of such states as refused to surrender fugitive slaves owned by Virginia masters. In March 1857 he became secretary of war in President Buchanan's cabinet, where his lack of administrative ability was soon apparent. In December 1860, on ascertaining that Floyd had honoured heavy drafts made by government contractors in anticipation of their earnings, the president requested his resignation. Several days later Floyd was indicted for malversation in office, but the indictment was overruled on technical grounds. There is no proof that he profited by these irregular transactions; in fact he went out of the office...
financially embarrassed. Though he had openly opposed secession before the election of Lincoln, his conduct after that event, especially after his breach with Buchanan, fell under suspicion, and he was accused of having sent large stores of government arms to Southern arsenals in anticipation of the Civil War. In the last days of his term he apparently had such an intention, but during the year 1860 the Southern States actually received less than their full quota of arms. After the secession of Virginia he was commissioned a brigadier-general in the Confederate service. He was first employed in some unsuccessful operations in western Virginia, and in February 1862 became commander of the Confederate forces at Fort Donelson from which he fled with his army on the 16th of February. General Gideon J. Pillow, on the night of February 18, leaving General Simon B. Buckner to surrender to General Grant. A fortnight later President Davis relieved him of his command. He died at Abingdon, Virginia, on the 26th of August 1863.

FLOYER, SIR JOHN (1649-1734), English physician and author, was born at Hinters in Staffordshire, and was educated at Oxford. He practised in Lichfield, and it was by his advice that Dr Johnson, when a child, was taken by his mother to be touched by Queen Anne for the king's evil on the 9th of March 1712. He died on the 1st of February 1734. Floyer was an advocate of cold bathing, introduced the practice of counting the rate of the pulse-beats, and gave an early account of the pathological changes in the lungs associated with emphysema.

His writings include:—Ракемо-Влорис: or the Touchstone of Medicines, discovering the virtues of Vegetables, Minerals and Animals by a mathematical and mechanical method (1672); his first protracted work. Animal Humours described by their sensible Qualities (1669); An Enquiry into the right Use and Abuses of the hot, cold and temperate Baths in England (1697); A Treatise of the Asthma (1st ed., 1698); The ancient Apostles rhymed, or an Essay to prove cold Bathing bath safe and useful (London, 1702; several editions 18vo; abridged, Manchester, 1844, 12mo); The Physician's Pulse-watch (1707-1710); The Silvian Oracle, translated from the best Greek copy, and com- pared with the sacred Prophecies (1st ed., 1711); Two Essays: the first Essay concerning the Creation, Aethereal Bodies, and Offices of good and bad Angels; the second Essay concerning the Mosaic System of the World (Nottingham, 1712); An Exposition of the Revelations (1719); An Essay to restore the Dipping of Infants in their Baptism (1722); Medicina Gerocomica, or the Galenic Art of preserving old Men's Healths (1st ed., 1724); A Comment on forty-two Histories described by Hippocrates (1726).

FLUDD, or FLUD, ROBERT [ROBERTES DE FLEUTISNIUS] (1574-1657), English physician and mystical philosopher, the son of Sir Thomas Fludd, treasurer of war to Queen Elizabeth in France and the Low Countries, was born at Milgate, Kent. After studying at St John's College, Oxford, he travelled in Europe for six years, and became acquainted with the writings of Paracelsus. He subsequently returned to Oxford, became a member of Christ Church, took his medical degrees, and ultimately became a fellow of the College of Physicians. He practised in London with success, though it is said that he combined with purely medical treatment a good deal of faith-healing. Following Paracelsus, he endeavoured to form a system of philosophy founded on the identity of physical and spiritual truth. The universe and all created things proceed from God, who is the beginning, the end and the sum of all things, and to him they will return. The act of creation is the separation of the active principle (light) from the passive (darkness) in the bosom of the divine unity (God). The universe consists of three worlds; the archetypal (God), the macrocosm (the world), the microcosm (man). Man is the world in miniature, all the parts of both sympathetically correspond and act upon each other. It is possible for man (and even for the mineral and the plant) to undergo transformation and to win immortality. Fludd's system may be described as a materialistic pantheism, which, allegorically interpreted, he put forward as containing the real meaning of Christianity, revealed to Adam by God himself, handed down by tradition to Moses and the patriarchs, and revealed a second time by Christ. The opinions of Fludd had the burden of being refuted by Kepler. However, the word Fludian was used by Samuel Johnson, and particularly for the tail of a mill-race. It is used in America for a very narrow gorge running between precipitous rocks, with a stream thought by some to be the original inventor of the barometer. He was an ardent defender of the Rosicrucians, and De Quincey considers him to have been the immediate, as J. V. Andreae was the remote, father of freemasonry. Fludd died on the 9th of September 1637.

See J. B. Craven, Robert Fludd, the English Rosicrucian (1902), where a list of his works is given; A. E. White, The Real History of the Rosicrucians (1890); and H. English, Rosicrucians and Freemasons: J. Hunt, Religious Thought in England (1870), i. 240 seq. His works were published in 6 vols., Oppenheim and Gouda, 1638.

FLÜGEL, GUSTAV LEBERECHT (1862-1870), German orientalist, was born at Bautzen on the 18th of February 1802. He received his early education at the gymnasium of his native town. He then studied theology and philology at Leipzig. He gradually devoted his attention chiefly to Oriental languages, which he studied in Vienna and Paris. In 1832 he became professor at the Fürstenschule of St Afra in Meissen, but ill-health compelled him to resign that office in 1850, and in 1851 he went to Vienna, where he was employed in cataloguing the Arabic, Turkish and Persian manuscripts of the court library. He died at Dresden on the 5th of July 1876.

Flügel's chief work was an edition of the bibliographical and encyclopaedic production of Haji Khulla, with Latin translation (7 vols., London and Leipzig, 1835-1858). He also brought out an edition of the Koran (Leipzig, 1834 and again 1893); then followed Concor- dantia corum aedibus orientis selectarum, in six volumes, with his own editor's notes and his own translation of the whole (Leipzig, 1839); his edition of the Glaubensbuch der Luther'schen Schriften (Leipzig, 1862); Die grammatischen Schulen der Araber (Leipzig, 1862); and Ibn Kullubins Kranke der Lebensbeschreibungen (Leipzig, 1862). An edition of Kiddî-al-Führst, published after his death, contains many of his articles. He was also the founder of the monthly journal, unpublished, for the von Flügel, and the Wörterbuch der Geschichte der Kirche (Leipzig, 1872).

FLÜGEL, JOHANN GOTTFRIED (1788-1855), German lexicographer, was born at Barby near Magdeburg, on the 22nd of November 1788. He was originally a merchant's clerk, but emigrating to the United States in 1810, he made a special study of the English language, and returning to Germany in 1819, was in 1824 appointed lector of the English language in the university of Leipzig. In 1838 he became American consul, and subsequently representative and correspondent of the Smithsonian Institution at Washington and several other leading American literary and scientific institutions. He died at Leipzig on the 24th of June 1855.

The fame of Flügel rests chiefly on the Vollständige englisch-deutsche und deutsch-englische Wörterbuch, first published in 2 vols. (Leipzig) in 1830, which has had an extensive circulation not only in Germany but in England and America. In this work he was assisted by J. Sporschil, a new and enlarged edition; edited by his son Felix Flügel (1892-1904), was published at Brunswick (1890- 1894). A further edition, with a German and English dictionary added, by Schmidt and S. Tanger appeared (Brunswick, London & New York) in 1906. Among his other works are:—Vollständige englisch-deutsche Sprachlehrbuch (1824-1826); Triologie, or dass kaumfamäisches Wörterbuch in drei Sprachen, Deutsch, Englisch, Französisch, and kamfamäisches Wörterbuch in drei Sprachen (1840); and Praktisches Handbuch der engl. Handelscorrespondenz (1827, 9th ed. 1831), these having passed through several editions. Flügel also published in the English language: A series of Commercial Letters (Leipzig, 1822), a 9th edition of which appeared in 1874 under the title Practical Mercantile Correspondence and a Practical Dictionary of the English and German Languages (2 vols., Hamburg and Leipzig, 1847-1852; 15th ed., Leipzig, 1891). The last was continued and re-edited by his son Felix.

FLUKÉ (probably connected with the Ger. flach, flat), a name given to several kinds of fish, flat in shape, especially to the common flounder; also the name of a trematoid worm, resembling a flounder in shape, which as a parasite infects the liver and neighbouring organs of certain animals, especially sheep, and causes liver-rot. The most common is the Fasciola hepatica (see Trematodes). It is also the name of a species of kidney potato. Probably from a resemblance to the shape of the fish, "fluke" is the name given to the holding-plates, triangular in shape, at the end of the arms of an anchor, and to the triangular extremities of the tail of a whale. The use of the word as a slang expression for a lucky accident appears to have been first applied in billiards to an unintentional scoring shot.

FLUME (through an O. Fr. word flum, from the Lat. flumen, a stream; compared with O. Ger. fluem, a stream, and particularly for the tail of a mill-race. It is used in America for a very narrow gorge running between precipitous rocks, with a stream...
at the bottom, but more frequently is applied to an artificial red channel of wood or other material, or for the diversion of a stream of water from a river for purposes of irrigation, for running a sawmill, or for various processes in the hydraulic method of gold-mining (see Aqueduct).

FLUMINI MAGGIORE, a town of the province of Cagliari, Sardinia, 10 m. by road N. of Iglesias, and 3 m. from the W. coast. Pop. (1901) town 3905; commune 9647. It is the centre of a considerable lead and zinc mining district. Three miles to the S. are the ruins of a temple erected probably in the time of Commodus (Corpus inscr. Lat. x., Berlin, 1883, No. 7539). They are located on the site of Metalla (mines), a station on the coast road from Sulci to Tharros, and the centre of the mining district in Roman times. At Flumini Maggiore itself were found two ingots of lead, one bearing a stamp with Hadrian's name.

FLUORANTHENE, C14H10, also known as idril, a hydrocarbon occurring with phenanthrene, pyrene, diphenyl, and other substances in "Stupp" fat (the fat obtained in working up the mercury ores in Idría), and also in the higher boiling fractions of the coal tar distillate. It was discovered by R. Fittig in 1878, who, with Gebhard and H. Liepmann, elucidated its constitution (see Ann., 1879, 200, p. 1). The hydrocarbons are separated from the "Stupp" by means of alcohol, the soluble portion of the distillation giving first phenanthrene and then a mixture of pyrene and fluoranthene. From the tar distillate, the chrysene can be fractionally precipitated, and the fluoranthene can be separated from most of the pyrene by fractional distillation in a partial vacuum. In either case the two hydrocarbons are finally separated by fractional crystallization of their picrates, which are then decomposed by ammonia. Fluoranthene crystallizes in large slender needles or monoclinic tables, melting at 100-110° C. and boiling at 250-251° C. (60 mm.). It is easily soluble in hot alcohol, ether and carbon bisulphide. On distillation with chromic acid it forms a quinone, C14H8O2, and an α-diphenylene ketocarboxylic acid C14H8O4. The picrate melts at 182-183° C.

FLUORENE (α-diphenylene methane), C14H10 or (C6H5)2CH, a hydrocarbon found in coal-tar. It is obtained from the higher boiling fractions, after separation of naphthalene and anthracene, by fractional distillation, the portion boiling between 290-340° C. being taken. The fluorene is separated from this by placing it in a freezing mixture, and is then redistilled or crystallized from glacial acetic acid, or purified by means of its picrate. It may be prepared by distilling diphenyleneketone over zinc dust, or by heating it with hydroiodic acid and phosphorus to 150-160° C.; and also by passing the vapour of diphenylmethane through a red hot tube. It crystallizes in colourless plates, possessing a violet fluorescence, melting at 112-113° and boiling at 295-297° C. By oxidation with chromic acid in glacial acetic acid solution, it is converted into diphenyleneketone (C14H8O2); whilst on heating with hydroiodic acid and phosphorus to 250-256° C. it gives a hydro derivative of composition C14H2O.

FLUORESCIN, or RESORCIN-PHTHALEIN, C16H12O4, in chemistry, a compound discovered in 1876 by A. V. Baeyer by the condensation of phthalic anhydride with resorcin at 195-260° C. (Ann., 1876, 183, p. 1). The two reacting substances are either heated alone or with zinc chloride for some hours, and the melt obtained is boiled out with water, washed by dilute alcohol, extracted by means of sodium hydrate, and the solution so obtained is precipitated by an acid. The precipitate is well washed with water and then dried. By repeating this process two or three times, the fluorescein may be obtained in a very pure condition. It forms a yellow amorphous powder, insoluble in water but soluble in alcohol, and crystallizing from the alcoholic solution in small dark red nodules. It is readily soluble in solutions of the caustic alkalis, the solution being of a dark red colour and showing (especially when largely diluted with water) a brilliant green fluorescence. It was so named on account of this last character. By browning with hydrogen chloride and a solution of copper sulphate, fluorescein (or copper-fluorescein) is obtained, the same compound being formed by heating 3,5-dibrom-2,4-dioxybenzoylbenzoic acid above its melting point (R. Meyer, Ber., 1805, 28, p. 1576). It crystallizes from alcohol in yellowish red needles, and dyestuffs, silk, wool, and mordanted cotton a fine pink colour. When heated with caustic alkalis it yields dibromanthraquinone dibromphenanthrin. The corresponding iod compound is known as erythrosin. Fluorescein is readily nitrated, yielding a di- or tetra-nitro compound according to conditions. The entrance of the negative nitro group into the molecule weakens the central pyrrole ring in the fluorescein nucleus and the di- and tetra-nitro compounds readily yield hydrates (see J. T. Hewitt and B. W. Perkins, Jour. Chem. Soc., 1900, p. 1326). By the action of ammonia or amines the di-nitro fluoresceins are converted into yellow dyestuffs (F. Re鸢erlin, Ber., 1897, 30, p. 332). Other dyestuffs obtained from fluorescein include the merocyanine (tetrazotated fluorescein) and rose Bengal (tetrazotatedtetrachlorofluorescein).

On fusion with caustic alkali, fluorescein yields resorcin, C14H12O4, and monoresorcin phthahlein (dioxylbenzoylbenzoic acid), (H2O)2C6H5-CO-C6H4-CO-HCOOH. With zinc dust and caustic soda it yields fluorescein. By warming fluorescein with excess of phosphorus pentachloride it yields fluorescein chloride, C14H8O3Cl (A. Baeyer), which crystallizes from alcohol in small prisms, melting at 252° C. When heated with fuller's earth and aniline hydrochloride, fluorescein yields a colourless aniline salt (O. Fischer and E. Hepp, Ber., 1893, 26, p. 2236), which is readily methylated by methyl iodide and potash to a fluoresceinmilkidelidimethyl ether, which when heated between 150° and 180° C. decomposes to 198° C. On the other hand, by heating fluorescein with caustic methyl iodide and monomethyl alcohol a coloured (yellow) dimethyl ether, melting at 186° C., is obtained (Fischer and Hepp). By heating the coloured dimethyl ether with caustic soda, the monomethyl ether is obtained (O. Fischer and E. Hepp, Ber., 1893, 26, p. 397); this crystallizes in triclinic tables, and melts at 262° C. It is to be noted that the colourless monomethyl ether fluoresces strongly in alkaline solution, the dimethyl ether of melting point 195° C. giving a yellowish solution. These two substances are identical with the ethers of carbonic, anhydride residue. G. Heller (Ber., 1895, 28, p. 312), however, showed that monoresorcin-phthalein when brominated in glacial acetic acid gives a dibrom derivative which, with furning sulphuric acid, yields dibromxanthopurpurin (1,3-dioxyl-2,4-dibromanthraquinone), a reaction which is only possible if the fluorescein (from which the monoresorcin-phthalein is derived) contains free hydroxyl groups in the para position to the linking carbon atom of the phthalic anhydride residue.

FLUORESCENCE. In a paper read before the Royal Society of Edinburgh in 1833, Sir David Brewster described a remarkable phenomenon he had discovered to which he gave the name of "internal dispersion." On admitting a beam of sunlight, condensed by a lens, into a solution of chlorophyll, the green colouring matter of leaves (see fig. 1), he was surprised to find that the beam of light was marked by a bright light of a blood-red colour, strangely contrasting with the beautiful green of the fluid when seen in moderate thickness. Brewster afterwards observed the same phenomenon in various vegetable solutions and essential oils, and in some solids, amongst which was fluor-spar. He believed this effect to be due to coloured particles held in suspension. A few years later, Sir John Herschel independently discovered that if a solution of quinine sulphate, which, viewed by transmitted light, appears colourless and transparent like water, were illuminated by a beam of ordinary daylight, a peculiar blue colour was seen in a thin stratum of the fluid adjacent to the surface by which it was entered. The light was unpolarized and passed freely through many inches of the fluid. The incident beam, after having passed through the stratum from which the blue light came, was not sensibly enfeebled or coloured, but yet it had lost the power of

Fig. 1.
producing the characteristic blue colour when admitted into a second solution of quinine sulphate. A beam of light modified in this mysterious manner was called by Herschel "epipolozed." Brewster showed that epipoloz was merely a particular case of internal dispersion, peculiar only in this respect, that the rays capable of dispersion were dispersed with unusual rapidity.

The investigation of this phenomenon was afterwards taken up by Sir G. G. Stokes, to whom the greater part of our present knowledge of the subject is due. Stokes's first paper "On the Change of the Refrangibility of Light" appeared in 1852. He repeated the experiments of Brewster and Herschel, and consideredly extended them. These experiments soon led him to the conclusion that the effect could not be due, as Brewster had imagined, to the scattering of light by suspended particles, but that the dispersed beam actually differed in refrangibility from the light which excited it. He therefore termed it "true internal dispersion" to distinguish it from the scattering of light, which he called "false internal dispersion." As this name, however, is apt to suggest Brewster's view of the phenomenon, he afterwards abandoned it as unsatisfactory, and substituted the word "fluorescence." This term, derived from fluor-spar after the analogy of opalescence from opal, does not presuppose any theory.

To examine the nature of the fluorescence produced by quinine, Stokes formed a pure spectrum of the sun's rays in the usual manner. A test-tube, filled with a dilute solution of quinine sulphate, was placed just outside the red end of the spectrum and then gradually moved along the spectrum to the other extremity. No fluorescence was observed as long as the tube remained in the more luminous portion, but as soon as the violet was reached, a ghost-like gleam of blue light shot right across the tube. On continuing to move the tube, the blue light at first increased in intensity and afterwards died away, but not until the tube had been moved a considerable distance into the ultra-violet part of the spectrum. When the blue gleam first appeared it extended right across the tube, but just before disappearing it was confined to a very thin stratum on the side at which the exciting rays entered. Stokes varied this experiment by placing a vessel filled with the dilute solution in a spectrum formed by a train of prisms. The appearance is illustrated diagrammatically in fig. 2. The greater part of the light passed freely as if through water, but from about half-way between the Fraunhofer lines G and H to far beyond the extreme violet, the incident rays gave rise to light of a sky-blue colour, which emanated in all directions from the portion of the fluid (represented white in fig. 2) which was under the influence of the incident rays. The anterior face of the blue space coincided, of course, with the inner surface of the glass vessel. The posterior surface marked the distance to which the incident rays were able to penetrate before they were absorbed. This distance was at first considerable, greater than the diameter of the vessel, but decreased with great rapidity as the refrangibility of the incident light increased, so that from a little beyond the extreme violet to the end, the blue space was reduced to an excessively thin stratum. This shows that the fluid is very opaque to the ultra-violet rays. The fixed lines in the violet and invisible part of the solar spectrum were represented by dark lines, or rather planes, intersecting the blue region. Stokes found that the fluorescent light is not homogeneous, for on reducing the incident rays to a narrow band of homogeneous light, and examining the dispersed beam through a prism, he found that the blue light consisted of rays extending over a wide range of refrangibility, but not into the ultra-violet.

Another method, which Stokes found especially useful in examining different substances for fluorescence, was as follows. Two coloured media were prepared, one of which transmitted the upper portion of the spectrum and was opaque to the lower portion, while the second was opaque to the upper and transmittent to the lower part of the spectrum. These were called by Stokes "complementary absorbents." No pair could be found which were exactly complementary, of course, but the condition was approximately fulfilled by several sets of coloured glasses or solutions. One such combination consisted of a deep-blue solution of ammoniacal copper sulphate and a yellow glass coloured with silver. The two media together were almost opaque. The light of the sun being admitted through a hole in the window-shutter, a white porcelain tablet was laid on a shelf fastened in front of the hole. If the vessel containing the blue solution was placed so as to cover the hole, and the tablet was viewed through the yellow glass, scarcely any light entered the eye, but if a paper washed with some fluorescent liquid were laid on the tablet it appeared brilliantly luminous. Different pairs of complementary absorbents were required according to the colour of the fluorescent light. This experiment shows clearly that the light which passed through the first absorbent and which would have been stopped by the second gave rise in the fluorescent substance to rays of a different wave-length which were transmitted by the second absorbent. Scattered light, with which the true fluorescent light was often associated, was eliminated by this method, being stopped by the second absorbent.

Stokes also used a method, analogous to Newton's method of crossed prisms, for the purpose of analysing the fluorescent light. A spectrum was produced by means of a slit and a prism, the slit being horizontal instead of vertical. The resulting very narrow spectrum was projected on a white paper moistened with a fluorescent solution, and viewed through a second prism with its refracting edge perpendicular to that of the first prism. In addition to the sloping spectrum seen under ordinary circumstances, another spectrum due to the fluorescent light alone, made its appearance, as seen in figs. 3 and 4. In this spectrum the colours do not run from left to right, but in horizontal lines. Thus the dark lines of the solar spectrum lie across the colours. The spectra in figs. 3 and 4 were obtained by V. Pierpont with an improved arrangement of Stokes's method. It will be seen that, in the case of chlorophyll, the whole spectrum, far into the ultra-violet, gives rise to a short range of red fluorescent light, while the effective part of the exciting light in the case of aesculin (a glucoside occurring in horse-chestnut bark) begins a little above the fixed line G and the fluorescent light covers a wide range extending from orange to blue.

Besides the substances already mentioned, a large number of vegetable extracts and some inorganic bodies are strongly fluorescent. Stokes found that most organic substances show signs of fluorescence. Green fluor-spar from Alston Moor exhibits a violet, uranium glass a yellowish-green fluorescence. Tincture of turmeric gives rise to a greenish light, and the extract of seeds of *Datura stramonium* a pale green light. Ordinary paraffin oil fluoresces blue. Barium platinocyanide, which is much used in the fluorescent screens employed in work with the Röntgen rays, shows a brilliant green fluorescence with ordinary light. Crystals of magnesium platinocyanide possess the remarkable property of emitting a polarized fluorescent light,
the colour and plane of polarization depending on the position of the crystal with respect to the incident beam, and, if polarized light is used, on the plane of polarization of the latter.

Stokes's Law.—In all the substances examined by Stokes, the fluorescent light appeared to be of lower refraction than the light which excited it. Stokes considered it probable that this lower refraction of the fluorescent light was a general law which held for all substances. This is what is known as Stokes's law. It has been shown, however, by E. Lommel and others, that this law does not hold generally. Lommel distinguishes two kinds of fluorescence. The bodies which exhibit the first kind are those which possess strong absorption bands, of which only one remains appreciable after great dilution. These bodies are always strongly coloured and show anomalous dispersion and (in solids) surface colour. In such cases, the maximum of intensity in the fluorescent spectrum corresponds to the maximum of absorption. Stokes's law is not obeyed, for a fluorescent spectrum can be produced by means of homogenious light of lower refrangibility than a great part of the fluorescent light. The second kind of fluorescence is the most common, and is exhibited by bodies which show absorption only in the upper part of the spectrum, i.e. they are usually yellow or brown or (if the absorption is in the ultra-violet) colourless. The absorption bands also are different from those of substances of the first kind, for they readily disappear on dilution. A third class of bodies is formed by those substances which exhibit both kinds of fluorescence.

Nature of Fluorescence.—No complete theory of fluorescence has yet been given, though various attempts have been made to explain the phenomenon. Fluorescence is closely allied to phosphorescence (q.v.), the difference consisting in the duration of the effect after the exciting cause is removed. Liquids which fluoresce only do so while the exciting light is falling on them, ceasing immediately the exciting light is cut off. In the case of solids, on the other hand, such as fluor-spar or uranium glass, the effect, though very brief, does not die away quite instantaneously, so that it is really a very brief phosphorescence. The property of phosphorescence has been generally attributed to some molecular change taking place in the bodies possessing it. That some such change takes place during fluorescence is rendered probable by the fact that the property depends upon the state of the sensitive substance; some bodies, such as barium platinocyanide, fluorescing in the solid state but not in solution, while others, such as fluorescein, only fluoresce in solution. Fluorescence is always associated with absorption, but many bodies are absorbent without showing fluorescence. A satisfactory theory would have to account for these facts at once, for the absorption of waves of one period by those of another, and the non-homogeneous character of the fluorescent light. Quite recently W. Voigt has sought to give a theory of fluorescence depending on the theory of electrons. Briefly, this theory assumes that the electrons which constitute the molecule of the sensitive body can exist in two or more different configurations simultaneously, and that these are in dynamical equilibrium, like the molecule in a partially dissociated gas. If the electrons have different periods of vibration in the different configurations, then it would happen that the electrons whose period nearly corresponded with that of the incident light would absorb the energy of the latter, and if they then underwent a transformation into a different configuration with a different period, this absorbed energy would be given out in waves of a period corresponding to that of the new configuration.

Applications of Fluorescence.—The phenomenon of fluorescence can be utilized for the purpose of illustrating the laws of reflection and refraction in lecture experiments since the path of a ray of light through a vessel containing a fluorescent substance is rendered visible. The existence of the dark lines in the ultra-violet portion of the solar spectrum can also be demonstrated in a simple manner. In addition to the foregoing applications, Stokes made use of this property for studying the character of the ultra-violet spectrum of different sources of illumination and flames. He suggested also that the property would in some cases furnish a simple test for the presence of a small quantity of a sensitive substance in an organic mixture. Fluorescent screens are largely used in work with Röntgen rays. There appears to be some prospect of light being thrown on the question of molecular structure by experiments on the fluorescence of vapours. Some very interesting experiments in this direction have been performed by R. W. Wood on the fluorescence of sodium vapour.

fluorides. The aqueous solution is strongly acid to litmus and dissolves most metals directly. Its most important property is that it rapidly attacks glass, reacting with the silica of the glass to form gaseous silicon fluoride, and consequently it is used for etching. T. E. Thorpe (Jour. Chem. Soc., 1896, 55, p. 163) determined the vapour density of hydrofluoric acid at different temperatures, and showed that there is no approach to a definite value below about 88° C. where it reaches the value 10-19 corresponding to the molecular formula HF; at temperatures below 88° C. the value increases rapidly, showing that the molecule is more complex in its structure. (For references see J. N. Friend, The Theory of Valency (1900), p. 111.) The aqueous solution behaves on concentration similarly to the other halogen acids; E. Deussen (Zeit. anorg. Chem., 1905, 44, pp. 300, 458; 1906, 49, 207) found the solution of constant boiling point to contain 43-3% HF and to boil at 110° (750 mm.)

The salts of hydrofluoric acid are known as fluorides and are easily obtained by the action of the acid on metals or their oxides, hydroxides or carbonates. The fluorides of the alkaline metals, of silver, and of most of the heavy metals are soluble in water; those of the alkaline earths are insoluble. A characteristic property of the alkaline fluorides is their power of combining with a molecule of hydrogen fluoride and with the fluorides of the more electropositive elements to form double fluorides, a behaviour not shown by other metallic halides. Fluorides can be readily detected by their power of etching glass when warmed with sulphuric acid; or by warming them in a glass tube with concentrated sulphuric acid and holding a moistened glass rod in the mouth of the tube, the water apparently gelatinizes owing to the decomposition of the silicon fluoride formed.

The atomic weight of fluorine has been determined by the conversion of calcium, sodium and potassium fluorides into the corresponding sulphates. J. Berzelius, by converting silver fluoride into silver chloride, obtained the value 19-44, and by analysing calcium fluoride the value 19-16; the more recent work of H. Moissan gives the value 19-05.

See H. Moissan, Le Fluor et ses composés (Paris, 1900).

**FLUOR-SPAR**, native calcium fluoride (CaF₂), known also as **FLUORITE** or **SIMPLE FLUOR**. In France it is called fluorine, whilst the term fluor is applied to the element (F). All these terms, from the Lat. fluere, "to flow," recall the fact that the spar is useful as a flux in certain metallurgical operations. (Cf. its Ger. name Flusspat or Fluß.)

Fluor-spar crystallizes in the cubic system, commonly in cubes, either alone or combined with the octahedron, rhombic dodecahedron, four-faced cube, &c. The four-faced cube has been called the fluoroid. In fig. 1, a is the cube (100), d the rhombic dodecahedron (110), and f the four-faced cube (310). Fig. 2 shows a characteristic twin of interpenetrant cubes. The crystals are sometimes polycrystalline, a large octahedron, e.g., being built up of small cubes. The faces are often etched or corroded. Cleavage is nearly always perfect, parallel to the octahedron.

Fluor-spar has a hardness of 4, so that it is scratched by a knife, though not so readily as calcite. Its specific gravity is about 3.1. The colour is very variable, and often beautiful, but the mineral is too soft for personal decoration, though it forms a handsome material for vases, &c. In some fluor-spar the colour is disposed in bands, regularly following the contour of the crystal. As the colour is usually expelled, or much altered, by heat, it is believed to be due to some organic pigment, and the presence of hydrocarbons has been detected in many specimens by G. Wyrouboff, and other observers. H. W. Morse (Proc. Amer. Acad., 1906, p. 557).

**Fig. 1.**

**Fig. 2.**

obtained carbon monoxide and dioxide, hydrogen and nitrogen and small quantities of oxygen from Weardale specimens by heating. He concluded that the gases are due to the decomposition of an organic colouring matter, which has, however, no connection with the fluorescence or thermo-luminescence of the mineral. Certain crystals from Cumberland are beautifully fluorescent, appearing purple with a bluish internal haziness by reflected light, and greenish by transmitted light. Fluor-spar, though cubic, sometimes exhibits weak double refraction, probably due to internal tension. Many kinds of fluor-spar are thermo-luminescent, i.e., they glow on exposure to a moderate heat, and the name of chlorophane has been given to a variety which exhibits a green glow. The mineral also phosphoresces under the König rays. Cavities containing liquid occasionally occur in crystals of fluor-spar, notably in the greasy green cubes of Weardale in Durham. A dark violet fluor-spar from Wilsendorf in Bavaria, evolves an odour of ozone when struck, and has been called antozonite. Ozone is also emitted by a violet fluor-spar from Quincié, dep. Rhône, France. In both cases the spar evolves free fluorine, which ozonizes the air.

Fluor-spar is largely employed by the metallurgist, especially in lead-smelting, and in the production of ferro-silicon and ferro-manganese. It is also used in iron and brass foundries, and has been found useful as a flux for certain gold-ores and in the reduction of aluminium. It is used as a source of hydrofluoric acid, which it evolves when heated with sulphuric acid. The mineral is also used in the production of opal glass and enamel ware. In consequence of its low refractive and dispersive power, colourless pellucid fluor-spar is valuable in the construction of apochromatic lenses, but this variety is rare. The dark violet fluor-spar of Derbyshire, known locally as "Blue John," is prized for ornamental purposes. It occurs almost exclusively at Tray Cliff, near Castleton. The dark purple spar, called by the workmen "bull beef," may be changed, by heat, to a rich emerald green, bright green, or yellowish green, but is far less difficult to work on the lathe, and is often toughened by means of resin. F. Corsi, the eminent Italian antiquary, held that fluor-spar was the material of the famous murrhine vases.

Fluor-spar is a mineral of very wide distribution. Some of the finest crystals occur in the lead-veins of the Carboniferous Limestone series in the north of England, especially at Weardale, Allendale and Alston Moor. It is also found in the lead and copper-mines of Cornwall and S. Devon, notably near Liskeard, where fine crystals have been found, with faces of the six-faced octahedron replacing the coronas of the cube. In Cornwall fluor-spar is known to the miners as "cann." Fine yellow fluor-spar occurs in some of the Saxon mines, and beautiful rose-red octahedra are found in the Alps, near Göschenen. Many localities in the United States yield fluor-spar, and it is worked commercially in a few places, notably at Rosiclare in southern Illinois.

**FLUSHING**, formerly a township and a village of Queens county, New York, U.S.A., on Long Island, at the head of Flushing Bay, since the 1st of January 1898 a part of the borough of Queens, New York City. Flushing is served by the Long Island railroad and by electric lines. It was settled in 1644 by a company of English non-conformists who had probably been residents of Flushing in Holland, from which the new place took its name. Subsequently a large number of Quakers settled here, and in 1672 George Fox spent some time in the township. Before the War of Independence Flushing was the country-seat of many rich New Yorkers and colonial officials.

**FLUSHING** (Dutch Vliissingen) is a fortified seaport in the province of Zeeland, on the north side of the island of Walcheren, at the mouth of the estuary of the western Scheldt, 4 m. by rail S. by W. of Middelburg, with which it is also connected by steam tramway and by a ship canal. There is a steam ferry to Breskens and Ter Neuzen on the coast of Zeeland-Flanders. Pop. (1900) 18,893. An important naval station and fortress up to 1867, Flushing has since expired, under the care of the Dutch government, to become a great commercial port. In 1872 the railway was opened which, in conjunction
with the regular day and night service of steamers to Queenborough in the county of Kent, forms one of the main routes between England and the east of Europe. In 1873 the great harbour, docks and canal works were completed. Yet the navigation of the port remains far behind that of Rotterdam or Antwerp, the tonnage being in 1899 about 7-9% of that of the kingdom. As a summer resort, however, Flushing has acquired considerable popularity, sea-baths and a large modern hotel being situated on the fine beach about three-quarters of an hour north-west of the town. It possesses a town hall, containing a collection of local antiquities, a theatre, an exchange, an academy of sciences and a school of navigation. The Jakobskerk, or Jacob's church, founded in 1328, contains monuments to Admiral de Ruyter (1607-1676) and the poet Jacob Bellamy (1757-1786), who were natives of Flushing. The chief industries of the town are connected with the considerable manufacture of machinery, the state railway-workshops, shipbuilding yards, Krupp iron and steel works' depot, brewing, and oil and soap manufacture. The chief imports are colonial produce and wine, wood and coal. The exports include agricultural produce (wheat and beans), shrimp and meat.

**FLUTE**

**FLUTE**, a word adapted from O. Fr. *flûte*, modern *flûte*; from O. Fr. have come the Span. *flauta*, Ital. *flauto* and Ger. *Flöte*. The *New English Dictionary* dismisses the derivations suggested from Lat. *flavium* or *flavatur*; ultimately the word must be referred to the root seen in "blow," Lat. *fluere*, Ger. *blasen*, &c. "Flute" is a general term applied to woodwind instruments consisting of a pipe pierced with lateral holes and blown directly through the mouthpiece without the intervention of a reed. The flute family is classified according to the mouthpiece used to set in vibration the column of air within the tube: i.e. (1) the simple lateral mouth-hole or embouchure which necessitates holding the instrument in a transverse position; (2) the whistle or nipple mouthpiece which allows the performer to hold the instrument vertically in front of him. There is a third class of pipes included among the flutes, having no mouthpiece of any sort, in which the column of air is set in vibration by blowing obliquely across the open end of the pipe, as in the ancient Egyptian nay, and the pan-pipe or syrinx (q.v.). The transverse flute has entirely superseded the whistle flute, which has survived only in the so-called penny whistle, in the "flute-work" of the organ (q.v.), and in the French flageolet.

The Transverse Flute or German Flute (Fr. *flûte traversière*, *flûte allemande*: Ger. *Flöte*, Querflöte, Zwirchpfeife, Schweberpfeife; Ital. *flauto traverso*) includes the concert flute known both as flute in C and as flute in D, the piccolo (q.v.) or octave flute, and the *flöte* (q.v.). The modern flute consists of a tube of a certain length, open at one end and nominally closed at the other by means of a plug or cork stopper; virtually, however, the tube is an open one giving the consecutive harmonic series of the open pipe or of a stretched string. The primitive flute was made in one piece, but the modern instrument is composed of three adjustable joints. (1) The head-joint, plugged at the upper end and containing at about one-third of the length the mouth-hole or embouchure. This embouchure, always open when the instrument is being played, converts the closed tube into an open one. In an accurate construction of the body, the holes and keys necessary to produce the scale which gave the flute its original designation of D flute, the head and body together, when the holes are closed, giving the fundamental note D. Before the invention of keys, this fundamental note and the notes obtained by the successive opening of the six holes produced the diatonic scale of D major. All other semitones were obtained by what is known as cross fingering (Fr. *doigt fourche*; Ger. *Gabelgriff*). It became usual to consider this the typical fingering nowadays; clarture, whatever the fundamental note given out by the flute, and to indicate the quality by the note given out when the six lateral holes are covered by the fingers. The result is that the tonality is always a tone lower than the name of the instrument indicates. Thus the D flute is really in C, the F flute is E, &c. (3) The foot-joint or tail-joint containing the two additional keys for C2 and C which extend the compass downwards, completing the chromatic scale of C in the fundamental octave. The compass of the modern flute is three octaves with chromatic semitones from $\text{C\textsuperscript{4}}$ to $\text{C\textsuperscript{7}}$. The sound is produced by holding the flute transversely with the embouchure turned slightly outwards, the lower lip resting on the nearer edge of the embouchure, and blowing obliquely across, not into, the orifice. The flat stream of air from the lips, known as the air-reed, breaks against the sharp outer edge of the embouchure. The current of air, thus set in a flutter, produces in the stationary column of air within the tube a series of pulsations or vibrations caused by the alternate compression and rarefaction of the air and generating sounds of a pitch proportional to the length of the stationary column, which is practically somewhat longer than the length of the tube.1 The length of this column is varied by opening the lateral finger-holes. The current or air-reed thus acts upon the air column within the flute, without passing through the tube, as a spectrum upon a string, setting it in vibration. The air column of the flute is the sound-producer, whereas in instruments with reed mouthpieces the vibrating reed is more properly the sound-producer, while the air column, acting as a resonating medium, reinforces the note of the reed by vibrating synchronously with it. If the angle2 by which the current of air is directed against the outer edge of the embouchure be made less acute and the pressure of the breath be at the same time increased, the frequency of the alternate pulses of compression and rarefaction within the tube will be increased two, three or fourfold, forming a corresponding number of nodes and loops which results in harmonics or upper partials, respectively the octave, the twelfth, the double octave. By this means sounds of higher pitch are produced without actually shortening the length of the column of air by means of lateral holes. The use of the flute in the concert is in most cases made on one of which there is great diversity of opinion. The subject is too vast to be treated here, but readers who wish to pursue it may consult the works of Rockstro,3 Helmholtz,4 and others.5 The effect of boring lateral holes in pipes is to shorten the vibrating length of the air column, which may be regarded as being effective only between the hole in question and the mouthpiece. In order to obtain this result the diameter of the hole should be equal to that of the bore; as long as the holes were covered by the fingers, obviously impossible. The holes, therefore, being smaller than the laws of acoustics demand, have to be placed proportionally nearer the mouthpiece in order to avoid deepening the pitch and deadening the tone. This principle was understood by wind-instrument makers of classic Greece (see AULOS and CLARINET), and has been explained by Chladni6 and Gottfried Weber.7

The bore of the early flute with six finger-holes was invariably cylindrical throughout, but towards the end of the 17th century a modification took place, the head joint alone remaining cylindrical while the rest of the bore assumed the form of a cone having its smallest diameter at the open end of the tube.

3 "Theorie der Luftschwingungen in Röhren mit offenen Enden" (Berlin, 1896). Ostwald's "Klassiker der exakten Wissenschaften, No. 80.
conoidal bore greatly improved the quality of tone and the production of the higher harmonics of the third octave. Once the conical bore had been adopted, the term flute was exclusively applied to the new instruments, the smaller flutes, then cylindrical, used in the army being designated fife (g.e.). At the present day in England, France and America, the favourite mode of construction is that introduced by Theobald Bochm, and known as the "cylinder flute with the parabolic head," of which more will be said further on. The successive opening of the holes and keys on the flute produces the chromatic scale of the first or fundamental octave. By increasing the pressure of the breath and slightly altering the position of the lips over the mouth-hole, the same fingering produces the notes of the fourth and fifth octaves. The third octave is, however, the most important, for the production of the higher harmonics (Fr. sous harmoniques; Ger. Flageolettone), of the fundamental scale, facilitated by the opening of certain of the finger-holes as "vent holes." The quality of tone depends somewhat on the material of which the flute is made; silver and gold produce a liquid tone of exquisite delicacy suitable for solo music, cocus-wood and ebonite a rich mellow tone of considerable power suitable for orchestral music. The tone differs further in the three registers, the lowest being slightly rough, the medium sweet and elegiac, and the third bird-like and brilliant. The proportions, position and form of the stopper and of the air-chamber situated between it and the embouchure are mainly influential in giving the flute its peculiarly soft hollow timbre, due to the conical section of the upper part of which according to Helmholz only the octave and twelfth are heard. Mr Blaikley states, however, that when the fundamental D is played, he can discern the seventh partial. The technical capabilities of the flute are practically unlimited to a good player who can obtain sustained notes diminuendo and crescendo, diatonic and chromatic scales and arpeggios both legato and staccato, leaps, turns, shakes, &c. By the articulation with the tongue of the syllables te-ke or ti-ke repeated quickly for groups of double notes, or of te-ke-ii for triplets, an easy effect staccato is produced, known respectively as double or triple tonguing, a device understood in the 16th century and mentioned by Martin Agricola, who gives the syllables as de for sustained notes, di-ri for shorter notes, and tel-lel-le for staccato passages in quick tempo.

Musical instruments, such as flutes, in which a column of air is set in vibration by regular pulsations derived from a current of air directed by the lips of the executant against the side of the orifice serving as embouchure, appear to be of very ancient origin. The Hindoos, Chinese and Japanese claim to have used these modes of blowing from time immemorial. The ancient Egyptians had a long pipe held obliquely and blown across the end of the pipe itself at its upper extremity; it was known as Sakt-ii and was frequently figured on the monuments. The same instrument, called "nay," is still used in Mahomedan countries. The oblique alous of the Greeks, plagiaulos, was of Egyptian origin and was perhaps at first blown from the end as described above, since we know that the Greeks were familiar with that method of blowing in the syrinx or pan-pipe. The instruments preserved at the British Museum having lateral embouchures show, however, that they were also acquainted—probably through the Hindustan—with the transverse flute, although in the case of these specimens a reed must have been inserted into the mouth-hole or no sound would have been obtained.

The high antiquity of a lateral embouchure in Europe is generally admitted; the flute evidently penetrated a period not yet determined. A transverse flute is seen on Indian sculptures of the Gandharan school showing Greek influence, and dating from the beginning of our era (fig. 3), but although the transverse flute was evidently known to the Greeks and Romans, it did not find the same favour as the reed instruments.

\[\text{Fig. 3.—Transverse Flute. 1st or 2nd century A.D. From the Tope at Amarilabhi, British Museum.}\]

During the early middle ages, instances of the flute occur on a group of caskets of Italo-Byzantine work of the 9th or 10th century, while of purely Byzantine origin we find examples of flutes in Greek manuscripts and in illuminated MSS. of the 10th century. The first time a flute is seen in a picture is in the Psalter of Charlemagne, in which some cymbrics, or flute-players, appear in the illumination in the 8th century. The conception of the flute by Charlemagne is still the same as that of the Schola Cantorum of the 5th century. In the first MS. of the Iliad in the British Museum, in the 9th century, the flute is depicted as the instrument of the muse Alcestis, and the flute-player is seen in the same position as in the MS. of the 10th century. In the MS. of the 11th century, the flute becomes larger and more progressive in style, and the flute-player is seen as a figure of the muse Calliope. In the MS. of the 12th century, the flute-player is seen as a figure of the muse Terpsichore, and the flute is larger and more progressive in style. In the MS. of the 13th century, the flute-player is seen as a figure of the muse Melpomene, and the flute is still larger and more progressive in style. In the MS. of the 14th century, the flute-player is seen as a figure of the muse Euterpe, and the flute is still larger and more progressive in style. In the MS. of the 15th century, the flute-player is seen as a figure of the muse Thalia, and the flute is still larger and more progressive in style. In the MS. of the 16th century, the flute-player is seen as a figure of the muse Erato, and the flute is still larger and more progressive in style. In the MS. of the 17th century, the flute-player is seen as a figure of the muse Clio, and the flute is still larger and more progressive in style.

\[\text{Fig. 2.—Boehm Cylinder Flute. Rockstro Model.}\]

1 See S. A. Howard, "The Aulos or Tuba," Harvard Studies, iv. (Boston, 1893), pp. 16-17.

2 Representations of flutes blown as here described have been found in Europe. See Comptes rendus de la commission impériale archéologique (St. Petersburg, 1867), p. 45, and atlas for the same date, pl. vi. Pompeian painting given by Helbig, Wandgemäld. No. 7607; Zahn, vol. ii. pl. 31; Museo Borbonico, pl. xv. No. 18; Clarac, pl. 120, 121, 129; Heuzey, Les Figures, p. 136.

3 There are two flutes at the British Museum (Catal. No. 4, 4 and 5 and 6), belonging to the Castellani collection, made of wood encased in bronze in which the mouthpiece, consisting of the head of a man, has a lateral hole bored obliquely into the main tube. This hole was probably intended for the reception of a reed. The pipe is stopped at the end beyond the mouthpiece as in the modern flute. There are six holes. See also the plagiaulos from Halicarnassus in the British Museum described by C. T. Newton in History of Discoveries at Halicarnassus (London), vol. ii. p. 339. The Louvre has two ancient statues (from the villa Borghese) representing satyrs playing upon transverse flutes. Unfortunately these may have been restored, especially in the details affecting our present subject, and are therefore examples of no value to us. Another statue representing a flute-player occurs in the British Museum. The instrument has been supposed to be a transverse flute, but erroneously, for the inscription of the lateral tube against which the instrumentalist presses his lips, could not, without the intervention of a reed, excite the vibratory movement of the column of air.

The first essentially western European trace of the transverse flute occurs in a German MS. of the 12th century, the celebrated Hortus deliciarum of the abbess Herrad von Landsberg.¹ Fol. 221 shows a syren playing upon the transverse flute, which Herrad explains in the margin thus: in the vocabulary of the latter it is termed *zweiglied*. In the 13th century it occurs among the miniatures of the fifty-one musicians in the beautiful MS. Las Cantigas de Santa Maria in the Escorial, Madrid.² Eustache Deschamps, a French poet, mentions in one of his ballads makes mention of the "flute traversaire," and we are justified in supposing that he refers to the transverse flute. It had certainly acquired some vogue in the 14th and 15th centuries as is shown in several of the manuscripts of Dufay, Ciconia, and other composers. In the MS. of the Dresden Codex, ²a, it is shown in use. In such cases, the tone of the flute is given by a long fingered bend, as is shown in the MS. of the Dresden Codex, ²a, which is from the battle of Marignan (1515), where the Swiss troops used it for the first time in war.

From Agricola onwards transverse flutes formed a complete family, said to comprise the descant, the alto and tenor, and the bass—respectively. Praetorius, designates the transverse flute as "Flauto traversiero," and "Feldpfeif," i.e. military flute, although the construction was the same. There were two kinds of *Feldpfeif* respectively; they were:

- the bass of *Feldpfeif*, and
- the sonata *Feldpfeif*.

Mersenne's account of the transverse flute, then designated "flûte d'Allemagne" or "flûte allemande," for in France, and an "Air de Cour" for the church. In this work, he led us to believe there were then in use in France at least two kinds or forms of the *fagotto*. The flautist of the Conservatory Royal of Brussels possesses specimens of all these varieties except the last. All of them are laterally pierced with six finger-holes; they have a cylindrical bore, and are fashioned out of a single piece of wood. Their compass consists of two octaves and a fifth. Mersenne's tabulation for fingering the flute differs but little from that of Hoteterre-le-Romain, and Eisel ² for the diatonic scale; he does not give the chromatic semitones, and the flute has ²⁴ keys. The largest bass flute in the Brussels museum is in used at the French normal pitch A ⁴⁴⁵ and vibrates per second. It measures 095 m. from the centre of the blow orifice to the lower extremity of the tube. The disposition of the lateral holes is such that it is impossible for the fingers if the flute is held in the ordinary way. The instrument must be placed against the mouth in an almost vertical direction, inclining the lower extremity of the tube to the right or left. This inconvenient position makes it necessary that the instrument should be divided into two parts, the latter being sharpened to turn the head joint that the embouchure may be most commodiously approached by the lips, which is not at all easy. The first and fourth of the lateral holes are double in order to accommodate both right- and left-handed players, the holes not in use being stopped with a little paper. The bass flute shown in fig. 4 is the facsimile of an instrument in the Museo Civico of Verona. The original, unfortunately no longer fits for use, is nevertheless sufficiently well preserved to allow of all its proportionate measurements being given. The lowest note, Eb, is obtained with a remarkable amplification of sound, thus upsetting a very prevalent opinion that it is impossible to produce by lateral illustration sounds which go a little lower than the ordinary limits of the principal bass flute. A bass flute in G similar to the one in fig. 5 is figured and described in Diderot and D'Alembert's encyclopédie (1751). According to Quanz,² it was in France and about the middle of the 17th century that the first modifications were introduced in the manufacture of the flute. The improvements at this period consisted of the abandonment of the cylindrical bore in favour of a conical one, with the base of the head of the instrument. At the same time the flute was made of three separate pieces called head, body, and tail or foot, which were ultimately further simplified. The body or middle of the flute was divided into two, so that the instrument could be tuned to the different pitches in use by a replacement with longer or shorter pieces. It was probably about 1677, when Lully removed the German instrument from the stage, that recourse was had for the first time to keys, and that the key of D♭ was applied to the lower part of the instrument.² The engraving of B. Picart, dated 1707, given in Hoteterre-le-Romain's book represents the flute as having five keys, and we are justified in supposing that the stage of improvement of which we have just spoken. In 1726 Quanz,² finding himself in Paris, had a second key applied to the flute, placed nearly at the same height as the first, that of the intended to differentiate the D♭ and the E♭. This innovation was generally well received in Germany, but does not appear to have met with corresponding success in other countries. In France and England manufacturers adopted it but rarely: in Italy it was declared useless.²

time flutes were constructed with the lower extremity lengthened sufficiently to produce the fundamental C, and furnished with a supplementary key to produce the C#. This innovation, spoken of by Quantz, did not meet with a very favourable reception, and was shortly afterwards superseded by that of Boehm. The improved method of drawing a flute with a C key in the Musical-Saal of J. F. B. Majer (Nuremberg, 1741), p. 45.

The intention of different pitsches was effected by changes in the length, and notably by substituting a longer or shorter upper piece in the middle joint. So wide were the differences in the pitches then in use that seven such pieces for the upper portion of the instrument were required. The improvement, on different parts of the instrument being altered by these modifications in the length, it was conceived that the just relation could be re-established by dividing the foot into two pieces, below the key. These were connected by a small screw, which could be turned by a coin, and it was asserted that, in this way, the foot could be lengthened proportionally to the length of the middle joint. Flutes thus improved took the name of ‘flutes à registre.’ The register system was, about 1752, applied by Quantz to the head joint, and the embouchure section being thus capable of elongation, it was allowable to the performer, according to the opinion of this professor, to lower the pitch of the flute a semitone without having recourse to other lengthening pieces, and without disturbing the accuracy of intonation.

The upper extremity of the flute, beyond the embouchure orifice, is maintained in fixed relationship to the lower extremity of this conical pipe, and depends, in a great measure, the accurate tuning of the flute. It is in its right place when the accompanying octaves are true. Quantz, in speaking of this accessory, mentions the name of a new instrument having the principle of the patent flute left unattempted. He does not name the inventor of this appliance, but, according to Tromlitz, the improvement was due to Quantz himself, and was called ‘Register oder Tiefenflute.’

The Method of Quantz applied there were still in use, besides the orchestral flute in D, the little fourth flute in G, the low fourth flute in A, and the flute d’amoire a note higher; in France, it was fashionable to adopt the little third flute in E. A bass flute in D had also been attempted (see fig. 5). When Ribbeck published his Bemerkungen über die Flöte the flute had already the five keys here shown. The author states that the invention of these keys is not known to him, but that—either Kusser, a musical instrument-maker in London, or Johann Georg Imberty, for whom—was the first that has since been able to trace those keys on the flutes of any other maker. Although Tromlitz does not claim for himself the invention of the keys for F, G# and Bb, he states that he had occupied himself for several years in applying these keys so as not to augment the difficulty of playing, but on the contrary to render the handling of them as easy as possible. In the later work published in 1800, however, he seems to attribute the invention of these keys to Richard Potter of London. He says that he has never seen a closing accompaniment to a good flute by that maker—the flute has certainly gained by the addition of the keys for F, G# and Bb, but this is not evident when a flute required performance of only one or two keys. ‘...Only a flute with eight keys according to my invention is capable of everything.’ It would seem, moreover, from circumstantial evidence stated clearly and on good authority by Ribbeck, that the keys for F, G#, and Bb, must have been used first in England and made by Richard Potter before 1774. The higher key of C adopted from 1760 to Tromlitz, we believe to have been first recommended by Ribbeck (1782). Tromlitz in De Flöten describes at length what may be termed the first systematic effort to overcome the difficulties created by the combination of open holes and closed keys. He attempted to solve the question by determining the positions of the holes according to the exigencies of fingering instead of subdividing them to the more arbitrary theories connected with the musical scale.

In 1785 Richard Potter improved Quantz’s slide applied to the head joint, which he received from Ribbeck. Potter by a double system of tubes forming double sliding-tight joints. In the document describing this improvement Potter patented the idea of lining the holes without the aid of adaptation keys. Potter’s patent conical valves were an adaptation of the contrivance first invented by J. F. Boile or Boyce of Göttingen.1

who used pewter for the plugs, and silver for lining the holes. The keys mentioned in the patent were four—D♭, F, G♯, A. The idea of extending the compass of the flute downwards was taken up again about the same time by two players of the flute in London named Tacet and Florio. They devised a new disposition of the keys C and C♯, and confided the execution of their invention to Potter. In Dr Arnold’s New Instructions for the German Flute occurs a tablature, the notation of which will be found at the end of the 18th century, and bears the following title, ‘A Complete Drawing and Concise Scale and Description of Tacet and Florio’s new invented German Flute, with all the additional keys explained.’ It explains the use of six keys, viz. D♭, D, E♭, E, F, G♯, in such a manner that the employment of so many keys was at once admitted. Tromlitz himself, who, however, made flutes with nine keys—adding E and G, among others—holds himself in favour of so great a complication, and that he preferred the flute with only three pairs of keys, D♭ and E♭, with a register foot joint and a cork nut-screw at the head joint. This instrument met all requirements. He was always much attached to the idea of the new and very important device of control of which there were only the two little fingers, and therefore this invention of Orazi proved a failure.

In 1808 the Rev. Frederick Nolan, of Stratford, near London, invented on open key, the lever of which, terminating by a ring permitted the closing of a lateral hole at the same time the key was being acted upon. The combination in this double action is the embryo of the mechanism that a little later was to transform the system of the flute. Two years later Macgregor, a musical-instrument maker in London, constructed a bass flute an octave lower than the ordinary flute. The idea was not new, as is proved by the existence of the bass flute in the eighteenth century, since he had been able to trace those keys on the Flute of any other maker. Although Tromlitz does not claim for himself the invention of the keys for F, G♯ and Bb, he states that he had occupied himself for several years in applying these keys so as not to augment the difficulty of playing, but on the contrary to render the handling of them as easy as possible. In the later work published in 1800, however, he seems to attribute the invention of these keys to Richard Potter of London. He says that he has never seen a closing accompaniment to a good flute by that maker—the flute has certainly gained by the addition of the keys for F, G♯ and Bb, but this is not evident when a flute required performance of only one or two keys. ‘...Only a flute with eight keys according to my invention is capable of everything.’ It would seem, moreover, from circumstantial evidence stated clearly and on good authority by Ribbeck, that the keys for F, G♯ and Bb, must have been used first in England and made by Richard Potter before 1774. The higher key of C adopted from 1760 to Tromlitz, we believe to have been first recommended by Ribbeck (1782). Tromlitz in De Flöten describes at length what may be termed the first systematic effort to overcome the difficulties created by the combination of open holes and closed keys. He attempted to solve the question by determining the positions of the holes according to the exigencies of fingering instead of subdividing them to the more arbitrary theories connected with the musical scale.

In 1785 Richard Potter improved Quantz’s slide applied to the head joint, which he received from Ribbeck. Potter by a double system of tubes forming double sliding-tight joints. In the document describing this improvement Potter patented the idea of lining the holes without the aid of adaptation keys. Potter’s patent conical valves were an adaptation of the contrivance first invented by J. F. Boile or Boyce of Göttingen.1

The old English apple flute, or flûte à bec, is described under the headings Recorder and Flageolet.

(V. M.; K. S.)

2. In architecture the name "flute" is given to the vertical channels (segmental, semicircular or elliptical in horizontal section) employed on the shafts of columns in the classic styles. The flutes are separated one from the other by an "arris" in the Doric order and by a "filet" in the Ionic and Corinthian orders. The earliest fluted columns are those in Egypt, at first with plain faces without any sinking, subsequently at Karnac (1400 B.C.) with a segmental sinking equal in depth to about one-seventh of the width of the flute. The columns flanking one of the "beehive" tombs at Mycenae have segmental flutes and are the earliest Greek examples. In two of the earliest Doric temples at Metapontum and Syracuse (temple of Apollo) the flutes are also segmental, but in later examples in order to emphasize the arris they were formed of three arcs and are known as "false ellipses," and this applies to nearly all the fluting in Greek examples whether belonging to the Doric, Ionic or Corinthian orders. The number of flutes varies, there being 52 in the archaic temple of Diana at Ephesus and from 30 to 52 flutes in the Persian columns according to the diameter of the column. In the Greek Doric column 20 is the usual number, but there are 16 only in the temples of Sunium, Assos, Segesta and the temple of Apollo at Syracuse; 18 in one of the temples of Selinus and the temple of Diana at Syracuse, and 24 in the temple of Neptune at Paestum. The depth of the flute also varies; in the Propylaea at Athens the radius is equal to the width of the flute and the flute is segmental. In the Parthenon the radius of the central part of the flute is greater than the width, but the smaller arcs on either side accentuate the curves of the flute. A similar accentuation is found in the Ionic and Corinthian orders, where the flutes are separated by fillets, and their section is always elliptical in Greek work, the depth of the flute, however, being always greater than in the Doric order. Thus, in the temple of Ilissus and the Ionic column in the cela of the temple at Bassae, the depth is about one-quarter of the width. In the Propylaea at Priene it is about one-third, and in the Erechtheum and other examples of the Greek Ionic order it is little more than one-half. The width of the fillet also varies, being as a rule one-quarter of the width of the flute; and the same applies to the Greek Corinthian order. In the Roman Doric, Ionic and Corinthian orders, the flute is either segmental or semicircular, its depth being about one-third of the width in the Doric column, and in all Ionic, Corinthian and Composite columns half the width of the flute. The fillet also is much broader in Roman examples, being about one-third of the width of the flute. In Roman buildings, sometimes: the flutes of the lower part of the shaft, about one-third of the height, are partly filled with a convex moulding, "casing" being the usual term applied to this treatment. The French architects of the 16th and 17th centuries carried this decorative feature much farther, and in the Tuileries and the Louvre carved a series of leaves in the flutes. In a few Italian buildings, instead of the fluting of the column being vertical, it twines round the column and is known as spiral fluting; a fine example is found in the Belvoira palace at Verona by San Michele. Fluting is sometimes introduced into capitals, as in the tomb of Mylasa, and in friezes, as in the theatre at Cnidos, the Incantada at Salonica, and a doorway at Patara. In one of the museums at Rome is a fine sarcophagus, the sides of which are sculptured with flutes in waved lines. The coronas of many of the Roman temples were carved with flutes. In medieval buildings, fluting was occasionally introduced in imitation of Roman work, as in the churches of central Syria and of Antun and St. John Lateran in the South of France. It has been said that the flutes of the shafts have seemed to have been brought in as a variety of treatment in the decoration of the shafts carrying the arches of cloisters, as at Monreal in Sicily and in those of St. John Lateran and St. Paul outside-the-Walls at Rome.

(R. P. S.)

FLUX (Lat. fluxus, a flowing; this being also the meaning of the English term in medicine, &c., in metallurgy, a substance introduced in the smelting of ores to promote fluidity, and to remove objectionable impurities in the form of a slag. The
substances in commonest use are:—lime or limestone, to slag off silica and silicates, flour-spar for lead, calcium and barium sulphates and calcium phosphate, and silica for removing basic alumina ores. Other substances are also used, but more commonly in assaying than in metallurgy. Sodium and potassium carbonates are valuable for fluxing off silica; mixed with potassium nitrate sodium carbonate forms a valuable oxidizing fusion mixture; “black flux” is a reducing flux composed of finely divided carbon and potassium carbonate, and formed by deflagrating a mixture of argol with 1 to 3 its weight of nitre. Borax is very frequently employed; it melts to a clear liquid and dissolves silica and many metallic oxides. Potassium bichromate is useful in the preliminary treatment of refractory alumina ores. Litharge and red lead are used in silver and gold assays, acting as solvents for silica and any metallic oxides present.

**FLY** (formed on the root of the supposed original Teut. *fliegen*, to fly), a designation applied to the winged or perfect state of many insects belonging to various orders, as in butterfly (see *Lepidoptera*), dragon-fly (q.v.), may-fly (q.v.), caddis-fly (q.v.), &c.; also especially employed by entomologists to mean any species of the two-winged flies, or *Diptera* (q.v.). In ordinary parlance *fly* is often used in the sense of the common house-fly (*Musca domestica*), and *May-fly* is the name by English sportsmen for the large may-fly *Ephemera* often found in South Africa in that of a species of tsetse-fly (*Glossina*), or a truant of country (“belts”) in which these insects abound (see *Tsetse-Fly*).

Apart from the house-fly proper (*Musca domestica*), which in England is the usual one, several species of flies are commonly found in houses; e.g. the *Stomoxys calcitrans*, or stable-fly; *Polllenia rudis*, or cluster-fly; *Musca stabulans*, another stable-fly; *Calliphora erythrocephala*, blue-bottle fly, blow-fly or meat-fly, with smaller sorts of blue-bottle, *Phormia terraenovae* and Locusta caesar; *Hornomomyia cantabrica* and brent, the small house-fly; *Scenginus* fenestratus, the black window-fly, &c.

But *Musca domestica* is far the most numerous, and in many places, especially in hot weather and in hot climates, is a regular pest. Mr L. O. Howard (Circular 71 of the Bureau of Entomology U.S. Dept. of Agriculture, Washington, 1906) says that in 1900 he made a collection of the flies in dining-rooms in different parts of the United States, and out of a total of 23,087 fishes, 22,500 were the common house-fly. Its geographical distribution is of the widest, and its rapidity of breeding, in manure and door-yard rubbish, so great that, as a carrier of diseases specially cholera and typhoid, the house-fly is now recognized as a potent source of danger; and various sanitary regulations have been made, or precautions suggested, for getting rid of it. These are discussed by Mr Howard in the paper referred to, but in brief they all amount to measures of general hygiene, and the isolation, prompt removal, or proper sterilization of the animal or human excrement in which these flies breed.

**FLYCATCHER**, a name introduced in ornithology by Ray, being a translation of the *Musicae* of older authors, and applied by Pennant to an extremely common English bird, the *M. grisola* of Linnaeus. It has since been used in a general and very vague way for a great many small birds from all parts of the world, which have the habit of catching flies on the wing. Ornithologists who have trusted too much to this characteristic and to certain merely superficial correlations of structure, especially those exhibited by a broad and rather flat bill and a gape beset by strong hairs or bristles, have associated under the title of *Musicae* an exceedingly heterogeneous assemblage of forms much reduced in number by later systematists. Great advantage is thereby lost in estimating the number of species specially the *Tolidae* and *Eurylaimidae*, as well as in excluding from it various members of the *Amphitrichidae*, *Coliuginae*, **Tyranidae**, *Vireonidae*, *Mniotilidae*, and perhaps others, which had been placed within its limits. These steps have left the *Musicaeidae* a purely Old-World family of the order *Passeres*, and the chief difficulty now seems to lie in separating it from the *Campephagidae* and the *Laniidae*. Only a very few of the forms of flycatchers (which, after all the deductions above mentioned, may be reckoned to include some 60 genera or subgenera, and perhaps 250 species) can here be even named.

The best-known bird of this family is that which also happens to be the type of the Linnaean genus *Musicae*—the spotted or grey flycatcher (*M. grisola*). It is a common summer visitor to nearly the whole of Europe, and is found throughout Great Britain, though less abundant in Scotland than in England, as well as in many parts of Ireland, where, however, it seems to be but locally and sparingly distributed. It is one of the latest migrants to arrive, and seldom reaches the British Islands till the latter part of May, when it may be seen, a small dust-coloured bird, sitting on the posts or railings of gardens and fields, ever now and then springing into the air, seizing with an audible snap of its bill some passing insect as it flies, and returning to it when it has quitted, or taking up some similar station to keep watch as before. It has no song, but merely a plaintive or peevish call-note, uttered from time to time with a jerking gesture of the wings and tail. It makes a neat nest, built among the small twigs which sprout from the hole of a large tree, fixed in the branches of some plant trained against a wall, or placed in any hole of the wall itself that may be left by the falling of a brick or stone. The eggs are from four to six in number, of a pale greenish-blue, or more or less fleshed with rust-colour. Silent and inconspicuous as it is, this bird, by its constant pursuit of flies in the closest vicinity of houses makes it a familiar object to almost everybody. A second British species is the pied flycatcher (*M. ariccapilla*), a much rarer bird, and in England not often seen except in the hilly country extending from the Peak of Derbyshire to Cumberland, and more numerous in the Lake District than elsewhere. It is not common in Scotland, and has only once been observed in Ireland. More of a woodland bird than the former, the brightly-contrasted black and white plumage of the cock; together with his agreeable song, readily attracts attention where it occurs. It is a summer visitor to all western Europe, but farther eastward its place is taken by a nearly allied species (*M. collaris*) in which the white of the throat and breast extends like a collar round the neck. A fourth European species (*M. para*), distinguished by its very small size and red breast, has also strayed some three or four times to the extreme south-west of England. This last belongs to a group of more eastern range, which has received generic recognition under the name of *Erythro sternia*, and it has several relations in Asia and particularly in India, where the allies of the pied flycatchers (*Ficedula de Brisson*) are found. One of this group, of special interest to the great spotted flycatcher (*Musicae* proper) is common to the two continents.

One of the most remarkable groups of *Musicaeidae* is that known as the paradise flycatchers, forming the genus *Tchthrea* of Lesson. In nearly all the species the males are distinguished by the growth of exceedingly long feathers in their tail, and by their putting on, for some part of the year at least, a plumage generally white, but almost always quite different from that worn by the females, which is of a more or less deep chestnut or bay colour, though in both sexes the crown is of a glossy steel-blue. They are found pretty well throughout Africa and tropical Asia to Japan, and seem to affect the deep shade of forests rather than the open country. The best-known species is perhaps the Indian *T. paradisi*; but the Chinese *T. incii*, and the Japanese *T. princeps*, from being very commonly represented by the artists of those nations on screens, fans and the like, are hardly less so; and the cock of the last named, with his bill of a pale greenish-blue and

1 Of the 30 genera or subgenera which Swainson included in his *Natural Arrangement and Relations of the Family of Flycatchers* (1838) he did not belong to the *Musicaeidae* at all, and one of them, *Todus*, not even to the order *Passeres*. It is perhaps impossible to name any ornithological work whose substance so fully belies its title as does this treatise. Swainson wrote it filled with faith in the so-called “Quinary System”—that fanciful theory invented by W. S. Macleay, which misled and kept back so many of the best English zoologists of his generation from the truth,—and, unconsciously swayed by his bias, his judgment was warped to fit his hypothesis.

2 By some writers this section is distinguished as *Butalis* of Boie, but do so seems contrary to rule.
eyes surrounded by bare skin of the same colour—though these are characters possessed in some degree by all the species—seems to be the most beautiful of the genus. *T. bontsi*, which is peculiar to the islands of Mauritius and Réunion, appears to be the only species in which the outward difference of the sexes is but slight. In *T. corineus* of the Seychelles, the adult male is wholly black, and his middle tail-feathers are not only very long but very bushy. In *T. mutata* of Madagascar, some of the males are found in a blackish plumage, though with the elongated median rectrices white, while in others white predominates over the whole body; but whether this sex is here actually masked, or whether the one dress is a passing phase of the other, is at present undetermined. Some of the African species, of which many have been described, seem always to retain the rufous plumage, but the long tail-feathers serve to mark the males.

A few other groups are distinguished by the brilliant blue they exhibit, as *Myiagra aurea*, and others as *Monarcha* (or *Aris*) *chrysomela* by their golden yellow. The Australian forms assigned to the *Musciapidae* are also very varied. *Suiru iniqua* has some of the habits of a water-wagtail (*Motacilla*), and hence has received the name of “despised wader.” It is also found in many parts of England on its analogue; and the many species of *Rhipidura* or fantailed flycatchers, which occur in various parts of the Australian region, have manners still more singular—turning over in the air, it is said, like a tumbler pigeon, as they catch their prey; but concerning the mode of life of the majority of the *Musciapidae*, and especially of the numerous African forms, hardly anything is known.

(A. N.)

**FLYGARE-CARLEN, EMILIE** (1807–1892), Swedish novelist, was born in Strömstad on the 8th of August 1807. Her father, Rutger Smith, was a retired sea-captain who had settled down as a small merchant, and she often accompanied him on the voyages he made along the coast. She married in 1827 a doctor named Axel Flygare, and went with him to live in the province of Småland. After his death in 1833 she returned to her old home and published in 1838 her first novel, *Waldemar Klein*. In the next year she removed to Stockholm, and married, in 1841, the jurist and poet, Johan Gabriel Carlen (1814–1875). Her house became a meeting-place for Stockholm men of letters, and for the next twelve years she produced one or two novels annually. The premature death of her son Edward Flygare (1829–1853), who had already published three books, showing great promise, was followed by six years of silence, after which she resumed her writing until 1884. The most famous of her tales are *Rosen på Tistelön* (1842; Eng. trans. *The Rose of Tistelö*; 1842); *Enslingen på Johannestaket* (1846; Eng. trans. *The Hermil, 4 vols., 1853*); and *Lät Kåpmanshus i skärgården* (1859; *The Merchant’s House on the Cliffs*). Frau Carlen published in 1876 *Minnen af svensk färjefart 1820–1850*, and in 1877–1888 three volumes of *Efterskärd från en 8a brång författarbana*, containing her last tales. She died at Stockholm on the 4th of February 1892. Her daughter, Rosa Carlen (1836–1883), was also a popular novelist.

Emilie Flygare-Carlen’s novels were collected in thirty-one volumes (Stockholm, 1869–1875).

**FLYING BUTTRESS**, in architecture, the term given to a structural feature employed to transmit the thrust of a vault across an intervening space, such as an aisle, chapel or cloister, to a buttress built outside the latter. This was done by throwing a semi-arch across to the vertical buttress. Though employed by the Romans and in early Romanesque work, it was generally masked by other constructions or hidden under a roof, but in the 12th century it was recognized as rational construction and emphasized by the decorative accentuation of its features, as in the cathedrals of Chartres, Le Mans, Paris, Beauvais, Reims, &c. Sometimes, owing to the height of the vaults, two semi-arches were thrown one above the other, and there are cases where the thrust was transmitted by two or even three buttresses across intervening spaces. As a vertical buttress, placed at a distance, possesses greater power of resistance to thrust than if attached to the wall carrying the vault, vertical buttresses as at Lincoln and Westminster Abbey were built outside the chapterhouse to receive the thrust. All vertical buttresses are, as a rule, in addition weighted with pinnacles to give them greater power of resistance.

**FLYING COLUMN**, in military organization, an independent corps of troops usually composed of all arms, to which a particular task is assigned. It is almost always composed in the course of operations, out of the troops immediately available. Mobility being its raison d’être, a flying column is when possible composed of picked men and horses accompanied with the barest minimum of baggage. The term is usually, though not necessarily, applied to forces under the strength of a brigade. The “mobile columns” employed by the British in the South African War of 1899–1902 were usually of the strength of two battalions of infantry, a battery of artillery, and a squadron of cavalry—almost exactly half that of a mixed brigade. Flying columns are mostly used in savage or guerrilla warfare.

**FLYING DUTCHMAN**, a spectre-ship popularly believed to haunt the waters around the Cape of Good Hope. The legend has several variants, but the commonest is that which declares that the captain of the vessel, Vanderdecken, was condemned for his blasphemy to sail round the cape for ever, unable to “make” a port. In the Dutch version the skipper is the ghost of the Dutch seaman Van Straaten. The appearance of the “Flying Dutchman” is considered by sailors an omen of disaster. The German legend makes one Herr Von Falkenberg the hero, and alleges that he is condemned to sail for ever around the North Sea, on a ship without helm or steersman, playing at dice for his soul with the devil. Sir Walter Scott says the “Flying Dutchman” was originally a vessel laden with bullion. A murder was committed on board, and thereafter the plague broke out among the crew, which closed all ports to the ill-fated craft. The legend has been used by Wagner in his opera *Der fliegende Holländer*.

**FLYING-FISH**, the name given to two different kinds of fish. The one (*Dactylopterus*) belongs to the gurnard family (*Triglidae*), and is more properly called flying gurnard; the other (*Exocoetus*) has been called flying herring, though more nearly allied to the gar-pike than to the herring. Some other fishes with long pectoral fins (*Pterois*) have been stated to be able to fly, but this has been proved to be incorrect.

The flying-gurnards are much less numerous than the *Exocoeti* with regard to individuals as well as species, there being only three or four species known of the former, whilst more than fifty have been described of the latter, which, besides, are found in numerous shoals of thousands. The *Dactylopterus* may be readily distinguished by a large bony head armed with spines, hard keeled scales, two dorsal fins, &c. The *Exocoeti* have thin, deciduous scales, only one dorsal fin, and the ventrals placed far backwards, below the middle of the body; some have long barbels at the chin. In both kinds the pectoral fins are greatly prolonged and enlarged, modified into an organ of flight, and in many species of *Exocoetus* the ventral fins are similarly enlarged, and evidently assist in the aerial evolutions of these fishes. Flying-fishes are found in the tropical and sub-tropical seas only, and it is a singular fact that the geographical distribution of the two kinds is nearly identical. Flying-fish are more frequently
FLYING-FOX—FLYING-SQUIRREL

observed in rough weather and in a disturbed sea than during calms; they dart out of the water when pursued by their enemies or frightened by an approaching vessel, but frequently also without any apparent cause, as is also observed in many other fishes; and they rise without regard to the direction of the wind or waves. The fins are kept quietly distended, without any motion, except an occasional vibration caused by the air whenever the surface of the wing is parallel with the current of the wind. Their flight is rapid, greatly exceeding that of a ship going 10 m. an hour, but gradually decreasing in velocity and not extending beyond a distance of 500 ft. Generally it is longer when the fishes fly against, than with or at an angle to, the wind. Any vertical or horizontal deviation from a straight line is not caused at the will of the fish, but by currents of the air; thus they

evening these bats bestir themselves, and fly off in companies to the village plantations, where they feed on all kinds of fruit, and so numerous and voracious are they that no garden crop has much chance of being gathered which is not specially protected from their attacks. The flying-fox of India (Pteropus medius) is a smaller species, but is found in great numbers wherever fruit is to be had in the Indian peninsula.

FLYING-SQUIRREL properly the name of such members of the squirrel-group of rodent mammals as have a parachute-like expansion of the skin of the flanks, with attachments to the limbs, by means of which they are able to take long flying-leaps from tree to tree. The parachute is supported by a cartilage attached to the wrist or carpus; in addition to the lateral membrane, there is a narrow one from the cheek along the front of each shoulder to the wrist, and in the larger species a third (interfemoral) connecting the hind-limbs with the base of the long tail. Of the two widely distributed genera, Pteromys includes the larger and Sciuropterus the smaller species. The two differ in certain details of dentition, and in the greater development in the former of the parachute, especially the interfemoral portion, which in the latter is almost absent. In Pteromys the tail is cylindrical and comparatively thin, while in Sciuropterus it is broad, flat and laterally expanded, so as to compensate for the absence of the interfemoral membrane by acting as a supplementary parachute.

In general appearance flying-squirrels resemble ordinary squirrels, although they are even more beautifully coloured. Their habits, food, &c., are also very similar to those of the true squirrels, except that they are more nocturnal, and are therefore less often seen. The Indian flying-squirrel (P. oral) leaps with its parachute extended from the higher branches of a tree, and descends first directly and then more and more obliquely, until the flight, gradually becoming slower, assumes a horizontal direction, and finally terminates in an ascent to the branch or trunk of the tree to which it was directed. The presence of these rodents at night is made known by their screaming cries. Sciuropterus is represented by S. songolola in eastern Europe and northern Asia, and by a second species in North America, but the other species of this genus and all those of Pteromys are Indo-Malayan. A third genus, Eupetocarus, typified by a very large, long-haired, dark-grey species from the mountains to the northeast of Kashmir (E. cinereus), differs from all other members of the squirrel-family by its tall-crowned molar teeth. It has a total length of 37 in., of which 22 are taken up by the tail.

In Africa the name of flying-squirrel is applied to the members of a very different family of rodents, the Anomaluridae, which are provided with a parachute. Since, however, this parachute is absent in some members of the family, the most distinctive character is the presence of a double row of spine scales on the underside of the tail, which apparently aid in climbing. The flying species are also distinguished from ordinary flying-squirrels by the circumstance that the additional bone serving for the support of the fore part of the flying-membrane rises

FIG. 2.—Exocoetus callopterus.

retain a horizontally straight course when flying with or against the wind, but are carried towards the right or left whenever the direction of the wind is at an angle with that of their flight. However, it sometimes happens that the fish during its flight immerses its caudal fin in the water, and by a stroke of its tail turns towards the right or left. In a calm the line of their flight is always also vertically straight or rather parabolic, like the course of a projectile, but it may become undulated in a rough sea, when they are flying against the course of the waves; they then frequently overtop each wave, being carried over it by the pressure of the disturbed air. Flying-fish often fall on board of vessels, but this never happens during a calm or from the lee side, but during a breeze only and from the weather side. In day time they avoid a ship, flying away from it, but during the night when they are unable to see, they frequently fly against the weather board, where they are caught by the current of the air, and carried upwards to a height of 20 ft. above the surface of the water, whilst under ordinary circumstances they keep close to it. All these observations point clearly to the fact that any deflection from a straight course is due to external circumstances, and not to voluntary action on the part of the fish.

A little Malacopterygian fish about 4 in. long has recently been described in West Africa which has the habits of a fresh-water flying-fish. It has been named Pseudobrutus. It has very large pectoral fins with a remarkable muscular process attached to the inner ray. It lives in fresh-water lakes and rivers in the Congo region, and has been caught in its flight above the water in a butterfly-net.

FLYING-FOX, or, more correctly, Fox-Bat. The first name is applied by Europeans in India to the fruit-eating bats of the genus Pteropus, which contains more than half the family (Pteropidae). This genus is confined to the tropical regions of the Eastern hemisphere and Australia. It comprises numerous species, a considerable proportion of which occur in the islands of the Malay Archipelago. The flying-foxes are the largest of the bats, the kalong of Java (Pteropus edulis) measuring about a foot in length, and having an expanse of wing-membrane measuring 5 ft. across. Flying-foxes are gregarious, nocturnal bats, suspending themselves during the day head-downwards by thousands from the branches of trees, where with their wings gathered about them, they bear some resemblance to huge shrivelled-up leaves or to clusters of some peculiar fruit. In Bhatian, according to Wallace, they suspend themselves chiefly from the branches of dead trees, where they are easily caught or knocked down by sticks, the natives carrying them home in basketfuls. They are then cooked with abundance of spices, and " are really very good eating, something like hare." Towards

Pigmy African Flying-Squirrel (Idiusus senkleri).
FLYSCH—FOG

from the elbow-joint instead of from the wrist. The family is
represented by two flying genera, Anomalurus and Idisius; the
latter containing only one very minute species (shown in the cut)
characterized by its small ears and elongated tail. Most of the
species are West African. In habits these rodents appear to be
very similar to the true flying-squirrels. The species without a
parachute constitutes the genus Zonokera, and looks very like an
ordinary squirrel. The Rodents have long ears.

In Australia and Papua the name flying-squirrel is applied to
such marsupials as are provided with parachutes; animals
which naturalists prefer to designate flying-phalangers (see
Marsupialia). (R.L.*).

FLYSCH, in geology, a remarkable formation, composed
mainly of sandstones, soft marls and sandy shales found extending
from S.W. Switzerland eastward along the northern Alpine zone
to the Vienna basin, whence it may be followed round the
northern flanks of the Carpathians into the Balkan peninsula.
It is represented in the Pyrenees, the Apennines, the Caucasus
and extends into Asia; similar flysch-like deposits are related
to the Himalayas as the European formations are to the Alps.
The Flysch is not of the same age in every place; thus in the
western parts of Switzerland the oldest portions probably belong
to the Eocene period, but the principal development is of
Oligocene age; as it is traced eastward we find in the east Alps
that it descends into the upper Cretaceous, and in the Vienna
region and the Carpathians it continues intercalations which clearly
indicate a lower Cretaceous horizon for the lower parts. It
appears that the type of formation was in progress of deposition at one period or another in the regions enumerated
above from Jurassic to late Tertiary times. The absence
of fossils from enormous thicknesses of Flysch makes the correlation
with other formations difficult; often the only indications
of organisms are the abundant markings supposed to represent
Algae (Chondrites, &c.), which have given rise to the term
"Hieroglyphic-sandstone." The most noteworthy exceptions
are perhaps the Oligocene fish-bed of Glarus, the Eocene nummulitic
beds in Calabria, and the Apyesch beds of Waidhofen.
Local phases of the Flysch have received special names; it is
the "Vienna" or "Carpathian" sandstone of those regions;
the "macigno" (a soft sandstone with calcareous cement) of the
Maritime Alps and Apennines; the "scaglio" (scaly clays)
and "alberese" (limestone) of the same places are portions of this
formation. The gris de Monten, the gris d'Annont of the
Basses Alps, and the gris d'Embrun of Chaitot appear in Switzerland
as the gris de Taxaynaas. At several places the upper
layers of the Flysch are iron-stained, as in the region of Leiman
and at the foot of the Dent du Midi; it is then styled the "Red
Flysch." Lentibular indications of gabbro, diabase &c., occupying
the Flysch of Calabria on the Pyrenees. Large exotic blocks of
granite, gneiss and other crystalline rocks in coarse conglomerates
are found near Vienna, near Sonthofen in Bavaria, near Lake Thun
(Wild Flysch) and at other points, which have been variously
regarded as indications of glaciation or of coastal conditions.

POČA (pronounced Futoscha), a town of Bosnia, situated at the
confluence of the Drina and Čehotina rivers, and encircled
by wooded mountains. Pop. (1893) 4,217. The town is the head-
quarters of a thriving industry in silver filigree-work, the silver
works having long been famous. The town is now largely
conquered by the forces of Montenegro and Novi Bazar, Poča,
then known as Chocha, was the scene of almost incessant border
warfare during the middle ages. No monuments of this period
are left except the Bogomil cemeteries, and the beautiful mosques,
which are the most ancient in Bosnia. The three adjoining
towns of Poča, Gorazda and Ustikolina were trading-stations
of the Ragusans in the 14th century, if not earlier. In the 16th
century, Benedetto Ramberti, ambassador for the Venetian
Republic, described the town, in his Libri Tre delle Case dei Turchi,
as Cosa, "a large settlement, with good houses in Turkish style,
and many shops and merchants. Here dwells the governor
of Herzegovina, whose authority extends over the whole of Servia.
Through this place all goods must pass, both going in and returning,
between Ragusa and Constantinople."

POCHABERS, a burgh of barony and village of Elginshire,
Scotland. Pop. (1901) 981. It is delightfully situated on the
Spey, about 9 m. E. by S. of Elgin, the terminus of a branch of the
Highland railway connecting at Orbilston Junction with the
main line from Elgin to Keith. The town was rebuilt in its
present situation at the end of the 18th century, when its earlier
site was required for alterations in the grounds of Gordon Castle,
in which the old town cross still stands. The streets all lead at
right angles to the central square, where fairs and markets are
held. The public buildings include a library and reading-room,
the court-house and the Milne school, named after Alexander
Milne, who endowed it with a legacy of $20,000. Adjoining the
town, surrounded by a park containing many magnificent old
trees, stands Gordon Castle, the chief seat of the duke of
Richmond and Gordon, erected in the 18th century. The anti-
quary George Chalmers (1742-1825) and the composer William
Marshall (1748-1833) were natives of the burgh.

FOCHSCHI (Rumanian Focșani, sometimes incorrectly written
Fokșani or Fokșan), the capital of the department of Putna,
Rumania; on the river Milcov, which formed the ancient
frontier of the former principalities of Moldavia and Walachia.
Pop. (1900) 23,783; of whom 6,000 were Jews. The chief buildings
are the prefecture, schools, synagogues, and many churches,
including those of the Armenians and Protestants. Focșani is
a commercial centre of some importance, the chief industries
being oil and soap manufacture and tannery. A large wine trade
is also carried on, and corn is shipped in lighters to Galatz.
The annual fair is held on the 29th of April. Government explora-
tions in the vicinity of this town show it to be rich in minerals
such as iron, copper, coal and petroleum. The line Focșani-
Galatz is covered by a very strong line of fortifications, known
as the Scree Linc. A congress between Russian and Turkish
diplomatists was held near the town in 1772. In the neighbour-
hood the Turks suffered a severe defeat from the Austrians and
Russians in 1789.

FOCUS (Latin for "hearth" or "fireplace"), a point at which
converging rays meet, toward which they are directed, or from
which diverging rays are directed; in the latter case called
the virtual focus (see MICROSCOPE; TELESCOPE; LENS).

In geometry the word is used to denote certain points (see
GEOMETRY; CONIC SECTION; and PERSPECTIVE).

FOG, the name given to any distribution of solid or liquid
particles in the surface layers of the atmosphere which renders
surrounding objects notably indistinct or altogether invisible
according to their distance. In its more intense forms it hinders
and delays travellers of all kinds, by sea or land, by railway,
road or even by the mountain ascent. It sometimes so thick as
to prevent traffic altogether. According to the New English
Dictionary the word "appears to be" is a back formation from
the adjective "foggy," a derivative of "fog" used with its old
meaning of aftermath or coarse grass, or, in the north of Britain,
of "moss." Such a formation would be reasonable, because
wreaths of fog in the atmospheric sense are specially character-
istic of meadows and marshes where fog, in the more ancient
sense, grows.

Two other words, mist and haze, are also in common use with
reference to the deterioration of transparency of the surface
layers of the atmosphere caused by solid or liquid particles,
and in ordinary literature the three words are used almost according
to the fancy of the writer. It seems possible to draw a distinction
between mist and haze that would be fairly well supported by
usage. Mist may be defined as a cloud of water particles at the
surface of land or sea, and would only occur when the air is nearly
or actually saturated, that is, when there is little or no difference
between the readings of the dry and wet bulbs; the word haze,
on the other hand, may be described in relation to the transparency of
the surface layers of the atmosphere when the air is dry.

It would not be difficult to quote instances in which even this
distinction is disregarded in practice. Indeed, the telegraphic
code of the British Meteorological Office uses the same figure for
mist and haze, and formerly the Beaufort weather notation had
no separate letter for haze (now indicated by z), though it
It is probable that sailors would be inclined to restrict the use of the word "fog" to such occasions from the point of view of cautious navigation. If cloud, drizzling rain, or heavy rain cause such obscurity that passing ships are not visible within working distances the soundings of a foghorn becomes a duty.

The number of occasions upon which fog and mist may be noted as occurring with winds of different strengths may be exemplified by the following results of thirty years for St. Mary's, Scilly Isles, where the observations have always been made by men of nautical experience.

The use of the word "fog" in the connexion "high fog," to describe the almost total darkness in the daytime occasionally noted in London and other large cities due to the persistent operation of the upper air without serious obscuration of the surface layers, is convenient but incorrect.

Regarding "fog" as a word used to indicate the state of the atmosphere as regards transparency considered with reference to its effect upon traffic, a scale of fog intensity has been introduced for use on land or at sea, whereby the intensity of obscurity is indicated by the numbers 1 to 5 in the table following. At sea or in the country a fog, as a rule, is white and consists of a cloud of minute water globules, of no great vertical thickness, which disperses the sunlight by repeated reflection but is fully translucent. In dust-storms and sand-storms dark or coloured fog clouds are produced such as those which are met with in the Harmattan winds off the west coast of Africa. In large towns the fog cloud is darkened and intensified by smoke, and in some cases may be regarded as due entirely to the smoke.

The physical processes which produce fogs of water particles are complicated and difficult to unravel. We have to account for the formation and maintenance of a cloud at the earth's surface; and the process of cloud-formation which is probably most usual in nature, namely, the cooling of air by rarefaction due to the reduction of pressure on ascent, cannot be invoked, except in the case of the fogs forming the cloud-caps of hills, which are perhaps not fairly included. We have to fall back upon the other process hitherto recognized as causing cloudy condensation in the atmosphere, that is to say, the mixing of masses of mist air of different temperatures. The mixing is brought about by the slow motion of air masses, and this slow motion is probably essential to the phenomenon.

Over the sea fog is most frequently due to the cooling of a surface layer of warm air by the underlying cold water. The amount of motion of the air must be sufficient to prevent the condensation taking place at the sea surface without showing itself as a cloud. In a research on the Life History of Surface Air Currents the changes incidental to the movement of the air over the north Atlantic Ocean were traced with great care, and the above examples (Tables I, II) taken from page 72 of the work referred to are typical of the formation of sea fog by the cooling of a relatively warm current passing over cold water.

In conformity with this suggestion we find that fog is most liable to occur over the open ocean in those regions where, as off the Newfoundland banks, cold-water currents underlie warm air, and that it is most frequent at the season of the year when the air temperature is increasing faster than the water temperature. But it is difficult to bring this hypothesis always to bear upon actual practice, because the fog is representative of a temperature difference which has ceased to exist. One cannot therefore observe under ordinary circumstances both the temperature difference and the fog. Doubtless one requires not only the initial temperature difference but also the slow drift of air which favours cooling of the lower layers without too much mixing and consequently a layer of fog close to the surface. Such a fog, the characteristic sea fog, may be called a cold surface fog.

From
the conditions of its formation it is likely to be less dense at the mast-head than it is on deck.

One would expect that a cold-air current passing over a warm sea surface would give rise to an ascending current of warmed air and hence cause cumulus cloud and possibly thunder showers rather than surface fog, but one cannot resist the conclusion that sea fog is sometimes formed by slow transference of cold air over relatively warm water, giving rise to what may be called a "steam-pot" fog. In such a case the actual surface layer in contact with the warm water would be clear, and the fog would be thicker aloft where the mixing of cold air and water vapour is more complete. Such fogs are, however, probably rare in comparison with the cold-water fogs. If the existence of a cold current over warm water were a sufficient cause of fog, as a current of warm air over cold water appears to be, the geographical distribution of notable fog would be much more widespread than it actually is, and the seasonal distribution of fog would also be other than it is.

The formation of fog over land seems to be an even more complicated process than over the sea. Certainly in some cases mistiness amounting to fog arises from the replacement of cold surface air which has chilled the earth and the objects thereon by a warm current. But this process can hardly give rise to detached masses or banks of fog. The ordinary land or valley fog of the autumn evening or winter morning is due to the combination of three causes, first the cooling of the surface layer of air at or after sunset by the radiation of the earth, or more particularly of blades of grass, secondly the slow downward flow (in the absence of wind) of the air thus cooled towards lower levels following roughly the course of the natural water drainage of the land, and thirdly the supply of moisture by evaporation from warm moist soil or from the relatively warm surface water of river or lake. In this way steam-pot fog gradually forms and is carried downward by the natural though slow descent of the cooled air. It therefore forms in wreathe on the lowest parts, until perhaps the whole valley becomes filled with a cloud of mist or fog. A case of this kind in the Lake District is minutely described by J. B. Cohen (Q. J. Roy. Met. Soc. vol. 30, p. 211, 1904).

It will be noticed that upon this hypothesis the circumstances favourable for fog formation are (1) a site near the bottom level of the drainage area, (2) cold surface air and no wind, (3) an evening or night of vigorous radiation, (4) warm soil, and (5) abundant moisture in the surface-soil. These conditions define with reasonable accuracy the circumstances in which fog is actually observed.

The persistence of these fog wreaths is always remarkable when one considers that the particles of a fog cloud, however small they may be, must be continually sinking through the air which holds them, and that unless some upward motion of the air keeps at least a balance against this downward fall, the particles of the cloud must reach the earth or water and to that extent the cloud must disappear. In sheltered valleys it is easy to suppose that the constant downward drainage of fresh and colder fog-laden material at the surface supplies the layers displaced from the bottom the necessary upward motion, and the result of this continuous falling of drops is only that the surface cloud gets thicker; but there are occasions when the extent and persistence of land fog seems too great to be accounted for by persistent radiation cooling. For example, in the week before Christmas of 1904 the whole of England south of the Humber was covered with fog for several days. It is of course possible that so much fog-laden air was poured down from the sides of mountains and hills that did project above the surface of the fog as to keep the lower reaches supplied for the whole time, but without more particulars such a statement seems almost incredible. Moreover, the drifting of fog banks over the sea seems capricious and unrelated to any known circumstances of fog formation, so that one is tempted to invoke the aid of electrification of the particles or some other abnormal condition to account for the persistence of fog. The observations at Kew observatory show that the electrical potential is abnormally high during fog, but whether that is the cause or the result of the presence of the water particles, we are not yet in a position to say. It must be remembered that a fog cloud ought to be regarded as being, generally speaking, in process of formation by mixing. Observations upon clouds formed experimentally in globes tend to show that if a mass of fog-bearing air could be enclosed and kept still for only a short while the fog would settle and leave the air clear. The apparently capricious behaviour of fog banks may be due to the fact that mixing is still going on in the persistent ones, but is completed in the disappearing ones.

One remarkable characteristic of a persistent fog is the coldness of the foggy air at the surface in spite of the heat of the sun's rays falling upon the upper surface of the fog. A remarkable example may be quoted from the case of London, which was under fog all day on 28th January 1909. The maximum temperature only reached 31° F., whereas at Walthamstow in Surrey from which the fog lifted it was as high as 46° F.

A priori we might suppose that the formation of fog would arrest cooling by radiation, and that fog would thus act as a protection of plants against frost. The condensation of water evaporated from wet ground, which affords the material for making fog, does apparently act as a protection, and heavy watering is sometimes used to protect plants from frost, but the same cannot be said of fog itself—cooling appears to go on in spite of the formation of fog.

A third process of fog-formation, namely, the descent of a cloud from above in the form of light drizzling rain, hardly calls for remark. In so far as it is subject to rules, they are the rules of clouds and rain and are therefore independent of surface conditions.

These various causes of fog-formation may be considered with advantage in relation to the geographical distribution of fog. Statistics on this subject are not very satisfactory on account of the uncertainty of the distinction between fog and mist, but a good deal may be learned from the distribution of fog over the north Atlantic Ocean and its various coasts as shown in the Monthly Meteorological Charts of the north Atlantic issued by the Meteorological Office, and the Pilot charts of the North Atlantic of the United States Hydrographic Office. Coast fog, which is probably of the same nature as land fog, is most frequent in the winter months, whereas sea fog and ocean fog is most extensive and frequent in the spring and summer. By June the fog area has extended from the Great Banks over the ocean to the British Isles, in July it is most intense, and by August it has notably diminished, while in November, which is provably a foggy month on land, there is hardly any fog shown over the ocean.

The various meteorological aspects of fog and its incidence in London were the subject of reports to the Meteorological Council by Captain A. Carpenter and Mr R. G. K. Lempert, based upon special observations made in the winters of 1901-1902 and 1902-1903 in order to examine the possibility of more precise forecasts of fog. The study of the properties and behaviour of fog is especially important for large towns in consequence of the economic and hygienic results which follow the incidence of dense fogs. The fogs of London in particular have been a subject of inquiry. It is difficult to get trustworthy statistics on the subject in consequence of the vagueness of the practice as regards the classification of fog. For large towns there is great advantage in using a fog scale such as that given above, in which one deals only with the practical range of vision irrespective of the meteorological cause.

For accepting the classification which distinguishes between fog and haze or mist, but not between the two latter terms, as equivalent to specifying fog when the thickness amounts to the figure 2 or more on the fog scale, we are enabled to compare the frequency of fog in London by the comparison of the results at the London observation stations. The comparison was made by Mr Brodie in a paper read before the Royal Meteorological Society (Quarterly Journal, vol. 31, p. 13), and it appears therefrom that in recent years there has been a notable diminution of fog.

FOGazzaro, Antonio (1842— ), Italian novelist and poet, was born at Vicenza in 1842. He was a pupil of the Abate Zanella, one of the best of the modern Italian poets, whose tender, thoughtful and deeply religious spirit continued to animate his literary productions. He began his literary career with Miranda, a poetical romance (1854), followed in 1876 by Valsodda, which, republished in 1886 with considerable additions, constitutes perhaps his principal claim as a poet, which is not inconsiderable.

The title grandeur of Carducci and D'Annunzio's impetuous torrent of melody Fogazzaro opposes a Wordsworthian simplicity and pathos, contributing to modern Italian literature wholesome elements of which it would otherwise be nearly destitute. His novels, Malombra (1882), Daniele Corris (1887), Mistero del Poeta (1888), obtained considerable literary success upon their first publication, but did not gain universal popularity until they were discovered and taken up by French critics in 1896. The demand then became prodigious, and a new work, Piccolo mondo antico (1896), which critics from friendly to Fogazzaro's religious and philosophical ideas pronounced the best Italian novel since I Promessi Sposi, went through numerous editions. Even greater sensation was caused by his novel Il Santo (The Saint, 1906), on account of its being treated as unorthodox by the Vatican; and Fogazzaro's sympathy with the Liberal Catholic movement—his own Catholicism being well known—made this novel a centre of discussion in the Roman Catholic world.

See the biography by Molmenti (1900).

FOGELBERG, Benedict (or Bengt) ERLAND (1786—1854), Swedish sculptor, was born at Gothenburg on the 8th of August 1786. His father, a copper-founder, encouraging an early exhibited taste for design, sent him in 1801 to Stockholm, where he studied at the school of art. There he came much under the influence of the sculptor Sergell, who communicated to him his own enthusiasm for antique art and natural grace. Fogelberg worked hard at Stockholm for many years, although his instinct for severe beauty rebelled against the somewhat rococo quality of the art that then prevailed in the city. In 1818 the grant of a government pension enabled him to travel. He studied from one to two years in Paris, first under Pierre Guérin, and afterwards under the sculptor Bosio, for the technical practice of sculpture. In 1820 Fogelberg realized a dream of his life in visiting Rome, where the greater part of his remaining years were spent in the assiduous practice of his art, and the careful study and analysis of the works of the past. Visiting his native country by royal command in 1854, he was received with great enthusiasm, but nothing could compensate him for the absence of those remains of antiquity and surroundings of free natural beauty to which he had been so long accustomed. Returning to Italy, he died suddenly of apoplexy at Trieste on the 22nd of December 1854. The subjects of Fogelberg's earlier works are mostly taken from classic mythology. Of these, Cupid and Psyche, "Venus entering the Bath," "A Bather" (1838), "Apollo Citharede," "Venus and Cupid" (1830) and "Psyche" (1854) may be mentioned. In his representations of Scandinavian mythology Fogelberg showed, perhaps for the first time, that he had powers above those of intelligent assimilation and imitation. His "Odin" (1831), "Thor" (1842), and "Balder" (1842), thought inspired by Greek art, display considerable power of independent imagination. His portraits and historical figures, as those of Gustavus Adolphus (1840), of Charles XII (1851), of Charles XIII (1852), and of Birger Jarl, the founder of Stockholm (1853), are faithful and dignified works.

FOGGIA, a town and episcopal see (since 1253) of Apulia, Italy, the capital of the province of Foggia, situated 243 ft. above sea-level, in the centre of the great Apulian plain, 201 m. by rail S.E. of Bari and 123 m. N.E. by E. of Naples. Pop. (1901) town, 49,631; commune, 53,134. The name is probably derived from the pits or cellars (fossae) in which the inhabitants store their grain. The town is the medieval successor of the ancient Arpi, to the N.; the Normans, after conquering the district from the Eastern empire, gave it its first importance. The date of the erection of the cathedral is probably about 1175; it retains some traces of Norman architecture, and the façade has a fine figured cornice by Bartolommeo da Foggia; the crypt has capitals of the 11th (7) century. The whole church was, however, much altered after the earthquake of 1731. A gateway of the palace of the emperor Frederick II. (1223, by Bartolommeo da Foggia) is also preserved. Here died his third wife, Isabella, daughter of King John of England. Charles of Anjou died here in 1284. After his son's death, it was a prey to internal dissensions and finally came under Alphonso I. of Aragon, who converted the pastures of the Apulian plain into a royal domain in 1445, and made Foggia the place at which the tax on the sheep was to be paid and the wool to be sold. The other buildings of the town are modern. Foggia is a commercial centre of some importance for the produce of the surrounding country, and is also a considerable railway centre, being situated on the main line from Bologna to Brindisi, at the point where this is joined by the line from Benevento and Caserta. There are also branches to Buccino and Potenza, and thence to either Avellino, Potenza, or Gioia del Colle, to Manfredonia, and to Lucera.

FOHNS (Ger., probably derived through Romansch favogn, fawogn, from Lat. favonium), a warm dry wind blowing down the valleys of the Alps from high central regions, most frequently in winter. The Fohn wind often blows with great violence. It is caused by the induction of air from the elevated region to areas of low barometric pressure in the neighbourhood, and the warmth and dryness are due to dynamical compression of the air as it descends to lower levels. Similar local winds occur in many parts of the world, e.g. in Sweden and on the slopes of the Rocky Mountains. In the southern Alpine valleys the Fohn wind is often called sirocco, but its nature and cause are different from the true sirocco. The belief that the warm dry wind comes from the Sahara dies hard; and still finds expression in some textbooks.

For a full account of these winds see Hann, Lehrbuch der Meteorologie, p. 594.

FOHR, a German island in the North Sea, belonging to the province of Schleswig-Holstein, and situated off its coast. Pop. 4500. It comprises an area of 32 sq. m., and is reached by a regular steamboat service from Husum and Dagebüll on the mainland to Wyk, the principal bathing resort on the E. coast of the island. The chief attraction of Wyk is the Sandwall, a
promenade which is shaded by trees and skirts the beach. Föhr, the most fertile of the North Frisian islands, is principally marshland, and comparatively well wooded. There are numerous pleasantly-situated villages and hamlets scattered over it, of which the most frequented are Boldixum, Nieblum and Alkermum. The inhabitants are mainly engaged in the fishing industry, and are of course as excellent seamen.

**FOIL**

1. (Through O. Fr. from Lat. folium, a leaf, modern Fr. feuille), a leaf, and so used in heraldry and in plant names, such as the “trefoil” clover; and hence applied to anything resembing a leaf. In architecture, the word appears for the small leaf-like spaces formed by the cusps of tracery in windows or panels, and known, according to the number of such spaces, as “quatrefoil,” “cinquefoil,” &c. The word is also found in “counterfoil,” a leaf of a receipt or cheque book, containing memoranda or a duplicate of the receipt or draft, kept by the receiver or drawer as a “counter” or check. “Foil” is particularly used of thin plates of metal, resembling a leaf, not in shape as much as in thinness. In thickness foil comes between “leaf” and “sheet” metal. In jewelry, a foil of silvered sheet copper, sometimes known as Dutch foil, is used as a backing for paste gems, or stones of inferior lustre or colour. This is coated with a mixture of isinglass and translucent colour, varying with the stones to be backed, or, if only brilliancy is required, left uncoloured, but highly polished. From this use of “foil,” the word comes to mean, in a figurative sense, something which by contrast, or by its own brightness, serves to heighten the attractive qualities of something else placed in juxtaposition. The commonest “foil” is that generally known as “tinfoil.” The ordinary commercial “tinfoil” usually consists chiefly of lead, and is used for the wrapping of chocolate or other sweetmeats, tobacco or cigarettes. A Japanese variegated foil gives the effect of “damaskening.” A large number of thin plates of various metals, gold, silver, copper, together with alloys of different metals are soldered together in a particular order, a pattern is hammered into the soldered edges, and the whole is hammered or rolled into a single thin plate, the pattern then appearing in the order in which the various metals were placed.

2. (From an O. Fr. fuler or foler, modern fouler, to tread or trample, to “full” cloth, Lat. fullo, a fuller, an old hunting term, used of the running back of an animal over its own tracks, to confuse the scent and baffle the hounds. It is also used in wrestling, of a “throw.” Thus comes the common use of the word, in a figurative sense, with reference to both these meanings, of baffling or defeating an adversary, or of parrying an attack.

3. As the name of the weapon used in fencing (see Fencing) the word is of doubtful origin. One suggestion, based on a supposed similar use of Fr. fleuré, literally a “little flower,” for the weapon, is that foil means a leaf, and must be referred in origin to Lat. folium. A second suggestion is that it means “blunted,” and is the same as (2). A third is that it is an adaptation of an expression “at foils,” i.e. “parrying.” Of these suggestions, according to the *New English Dictionary,* the first has nothing to support it, the second is not supported by any evidence that in sense (2) the word ever meant to blunt. The third has some support. Finally a suggestion is made that the origin is an adoption of an old word “foiln” meaning a thrust with a pointed weapon. The origin of this word is probably an O. Fr. foisne, from the Lat. fuscina, a three-pronged fork.

**FOIL-FENCING,** the art of attack and defence with the fencing-foil. The word is used in several spellings (foyle, file, &c.) by the English writers of the last half of the 16th century, but less in the sense of a weapon of defence than merely a weapon of attack. Blunt swords for use in fencing have been used in all ages. For the most part these were of wood and flat in general form, but when, towards the close of the 17th century, all cutting action with the small-sword was discarded (see Fencing), foil-blades were usually made of steel, and either round, three-cornered or four-cornered in form, with a button covering the point. The foil is called in French fleurd, and in Italian fioretto (literally “bud”) from this button. The classic small-

word play of the 17th and 18th centuries is represented at the present time by fencing with the épée de combat (fighting-rapier), which is merely the modern duelling-sword furnished with a button (see ÉPÉE-DE-COMBAT), and by foil-fencing. Foil-fencing is a conventional art, its characteristic limitation lying in the rule that no hits except those on the body shall be considered good, and not even those unless they be given in strict accordance with certain standard precepts. In épée-fencing on the contrary, a touch on any part of the person, however given, is valid. Foil-fencing is considered the basis, so far as practice is concerned, of all sword-play, whether with foil, épée or sabre.

There are two recognized schools of foil-fencing, the French and the Italian. The French method, which is now generally adopted everywhere except in Italy, is described in this article, reference being made to the important differences between the two schools.

The Foil.—The foil consists of the “blade” and the “handle.” The blade, which is of steel and has a quadrangular section, consists of two parts: the blade proper, extending from the guard to the button, and the “tongue,” which runs through the handle and is joined to the pommel. The blade proper is divided into the “forte,” or thicker half (next the handle), and the “foible” or thinner half. Some authorities divide the blade proper into three parts, the “forte,” “middle” and “foible.” The handle is comprised of the “guard,” the “grip” and the “pommel.” The guard is a light piece of metal shaped like the figure 8 (Fr. luneilles, spectacles) and backed with a piece of stiff leather of the same shape. The grip, which is grasped by the hand, is a hollow piece of wood, usually wound with twine, through which the tongue of the blade passes. The pommel is a piece of metal, usually pear-shaped, to which the end of the tongue is joined and which forms the extremity of the handle. The blade from guard to button is about 33 in. long (No. 5), though a somewhat shorter and lighter blade is generally used by ladies. The handle is about 8 in. long and slightly curved downwards.

The genuine Italian foil differs from the French in having the blade fuller, more flexible, and longer, and carrying on the handle, which consists of a thin, solid, bell-shaped guard from 4 to 5 in. in diameter, a straight grip and a light metal bar joining the grip with the guard, beyond the edge of which it extends slightly on each side. Of late years many Italian masters use French blades and even discard the cross-bar, retaining, however, the bell-guard.

In holding the foil, the thumb is placed on the top or convex surface of the grip (the sides of which are a trifle narrower than the top and bottom), while the palm and fingers grasp the other half of the guard. "Pronation" is the reverse position, with the knuckles up. The French lay stress upon holding the foil lightly, the necessary pressure being exerted mostly by the thumb and forefinger, the other fingers being used more to guide the direction of the executed movements. This is in order to give free scope to the doigté (fingering), or the faculty of directing the point of the foil by the action of the fingers alone, and includes the possibility of changing the position of the hand on the grip. Thus, in parrying, the end of the thumb is placed within half an inch, or even less, of the guard, while in making a lunge, the foil is held as near the pommel as possible, in order to gain additional length. It will be seen that doigté is impossible with the Italian foil, in holding which the forefinger is firmly interlaced with the cross-bar, preventing any movement of the hand. The lightness of grasp inculcated by the French is illustrated by the rule of the celebrated master Lafaugère: "Hold your sword as if you had a little bird in your hand, firm enough to prevent its escape, yet light enough so that you can move it as you please." This is illustrated by the fact that a disarmament is not considered of any value in the French school.

*To Come on Guard.*—The position of "on guard" is that in which the fencer is best prepared both for attack and defence. It is taken from the position of "attention"; the feet together and at right angles with each other, head and body erect, facing forward in the same direction as the right foot, left arm and hand hanging in touch with the body, and the right arm and foil...
FOIL-FENCING

forming a straight line so that the button is about 1 yd. in front of the feet and 4 in. from the floor. From this position the movements to come “on guard” are seven in number:—

1. Raise the arm and foil and extend them towards the adversary (or master) in a straight line, the hand being opposite the eye.
2. Drop the arm and foil again until the point is about 4 in. from the floor.
3. Swing the button round so that it shall point horizontally backwards, and hold the hilt against the left thigh, the open fingers of the left hand being held, knuckles down, against the guard and along the blade.
4. Carry the foil, without altering the position of the hands, above the head until the arms are fully extended, the foil being kept horizontal and close to the body as it is lifted.
5. Let the left arm fall back behind the head to a curved position, the hand being opposite the top of the head; at the same time bring the right hand down opposite the right breast and about 8 in. from it; keeping the elbow well in and the point of the foil directed towards the opponent’s eye.
6. Bend the legs by separating them at the knees but without moving the feet.
7. Shift the weight of the body on to the left leg and advance the right foot a short distance (from 14 to 18 in., according to the height of the fencer.

In the Italian school the fencer stands on guard with the right arm fully extended, the body more effaced, i.e. the left shoulder shouldered, and the feet somewhat apart. At the present time, however, many of the best Italian fencers have adopted the guard with crooked sword-arm, owing to their abandonment of the old long-foil blade.

The Recover (at the close of the lesson or assault).—To recover “in advance”: extend the right arm at right angles with the body, drop the left arm and straighten the legs by drawing the rear foot up to the one in advance. To recover “to the rear”: extend the right arm and drop the left as before, and straighten the legs by drawing the forward foot back to that in the rear.

The Salute always follows the recovery, the two really forming one movement. Having recovered, carry the right hand to a position just in front of the throat, knuckles out, foil vertical with point upwards; then lower and extend the arm with nails up until the point is 4 in. from the floor and slightly to the right.

To Advance.—On guard, take a short step forward with the right foot and let the left foot follow immediately the same distance, the position of the body not being changed. However the step, or series of steps, is made, the right foot should always move first.

To Retreat.—This is the reverse of the advance, the left foot always moving first.

The Calls (deux appel).—Being on guard, tap the floor twice with the right foot without altering the position of any other part of the person. The object of the calls is to test the equilibrium of the body, and they are usually executed as a preliminary to the recover.

The Lunge is the chief means of attack. It is immediately preceded by the movement of “extension,” in fact the two really form one combined movement. Extension is executed by quickly extending the right arm, so that point, hand and shoulder shall have the same elevation; no other part of the person is moved. The “lunge” is then carried out by straightening the left leg and throwing forward the right foot, so that it shall be planted as far forward as possible without losing the equilibrium or preventing a quick recovery to the position of guard. The left foot remains firmly in its position, the right shoulder is advanced, and the left arm is thrown down and back (with hand open and thumb up), to balance the body. The recovery to the position of guard is accomplished by smartly throwing the body back, and exertion of the right leg, until its weight rests again on the left leg, the right foot making some slight step back on guard positions. The point upon which the French school lays most stress is, that the movement of extension shall, if only by a fraction of a second, actually precede the advance of the right foot. The object of this is to ensure the accuracy of the lunge, i.e. the direction of the point.

The Gain.—This consists in bringing up the left foot towards the right (the balance being shifted), keeping the knees bent. In this manner a step is gained and an exceptionally long lunge can be made without the knowledge of the adversary. It is a common stratagem of fencers whose reach is short.

In the French school there are divided counters of all sorts which are divided into quarters, the two upper ones being called the “high lines,” and the two lower ones the “low lines.” Thus a thrust directed at the upper part of the breast is called an attack in the high lines. In like manner the parries are named from the different quarters they are designed to protect. There are four traditional parries executed with the hand in supination, and four others, practically identical in execution, made with the hand held in pronation. Thus the parries defending the upper right-hand quarter of the jacket are “tierce” (sixth, with the hand in supination) and “quarte” (fourth, in supination); those defending the upper left-hand quarter are “septime” (seventh, in supination). Those defending the lower right-hand quarter are “octave” (eighth, in supination) and “seconde” (second, in pronation). Those defending the lower left-hand quarter are “septime” (seventh, in supination), more generally called “demicircle,” or “half-circle”; and “prime” (first, in pronation).

The Parries.—The tendency of the French school has always been towards simplicity, especially of defence, and at the present day the parries made with the knuckles up (pronation), although recognized and taught, are seldom if ever used against a strong adversary in foil-fencing, owing principally to the time lost in turning the hand. The theory of parrying is to turn aside the opponent’s foil with the least possible expenditure of time and exertion, using the arm as little as possible while letting the hand and wrist do the work, and opposing the “forte” of the foil to the “foible” of the adversary’s. The foil is kept pointed as directly as possible towards the adversary, and the parries are made rather with the corners than the sides of the blade. The simplest movement as a parry is the turn of the opponent’s blade is the most perfect parry. There are two kinds of parries, “simple,” in which the attack is warded off by a single movement, and “counter,” in which a narrow circle is described by the point of the foil round that of the opponent, which is thus enveloped and thrown aside. There are also complex parries, composed of combinations of two or more parries, which are used to meet complicated attacks, but they are all resolvable into simple parries. In parrying, the arm is bent about at right angles.

Simple Parries.—The origin of the numerical nomenclature of the parries is a matter of dispute, but it is generally believed that they received their names from the positions assumed in the process of drawing the sword and falling on guard. Thus the position of the hand and blade, the moment it is drawn from the scabbard on the left side, is practically that of the first, or “prime,” parry. To go from “prime” to “seconde” it is only necessary to drop the hand and carry it across the body to the left side; thence to “tierce” is only a matter of raising the point of the sword, &c.

Parry of Prime (to ward off attacks on the—usually lower—left-hand side of the body). Hold the hand, knuckles up, opposite the left eye and the point directed towards the opponent’s knee. This parry is now regarded more as an elegant evolution than a sound means of defence, and is little employed.

Parry of Seconde (against thrusts at the lower right-hand side). This is executed by a quick, not too wide movement of the hand downwards and slightly to the right, knuckles up.

Parry of Tierce (against thrusts at the upper right-hand side). A quick, dry beat on the adversary’s “foible” is given, forcing it to the right, the hand, in pronation, being held opposite the middle of the right breast. This parry has been practically described in favour of the “tierce.”

Parry of Quarte (against thrusts at the upper left-hand side). This parry, perhaps the most used of all, is executed by forcing the adversary’s blade to the left by a dry heat, the hand being in supination, opposite the left breast.

Parry of Quinte (against thrusts at the left-hand side, like “quarte”). This is practically a low “quarte,” and is little used.
**Parry of Sixte** (against thrusts at the upper right-hand side). This parry is, together with "quarte," the most important of all. It is executed with the hand held in supination opposite the right breast, a quick, narrow movement throwing the adversary's blade to the right.

**Parry of Septime or Half-Circle** (against thrusts at the lower left-hand side) is executed by describing with the point of the foil a small semicircle downward and towards the left, the hand moving a few inches in the same direction, but kept thumb up.

**Parry of Octave** (against thrusts at the lower right-hand side) is executed by describing with the point of the foil a small semicircle downward and towards the right, the hand moving a few inches in the same direction, but kept thumb up.

**Counter Parries** (Fr. contre).—Although the simple parries are theoretically sufficient for defense, they are so easily deceived by feints that they are supplemented by counter parries, in which the blade describes narrow circles, following that of the adversary and meeting and turning it aside; thus the point describes a complete circle while the hand remains practically stationary. Each simple parry has its counter, made with the hand in the same position and on the same side as in the simple parry. The two most important are the "counter of quarte" and the "counter of septime," while the counters of "septime" and "octave" are less used, and the other four at the present time are practically never used.

**Counter of Quarte.**—Being on guard in quarte (with your adversary's blade on the left of yours), if he drops his point under and thrusts in sixte, in other words at your right breast, describe a narrow circle with your point round his blade, downward to the right and then up over to the left, bringing hand and foil back to their previous positions and catching and turning aside his blade on the way. The "Counter of Sixte" is executed in a similar manner, but the circle is described in the opposite direction, throwing off the adversary's blade to the right. The "Counters of Septime and Octave" are similar to the other two but are executed in the low lines.

**Complex or Combined Parries** are such as are composed of two or more parries executed in immediate succession, and are made in answer to feint attacks by the adversary (see below); e.g., being on guard in quarte, should the adversary drop his point under and feint at the right breast but deflect the point again and really thrust on the left, it is evident that the simple parry of sixte would cover the right breast but would leave the real point of attack, the left, entirely uncovered. The "Double," therefore, followed, as a continuation of the movement, by the parry of quarte, or a counter parry. The complex parries are numerous and depend upon the attack to be met.

**Engagement** is the junction of the blades, the different engagements being named from the parries. Thus, if both fencers are in the position of quarte, they are said to be engaged in quarte. To engage in another line (Change of Engagement) e.g. from quarte to sixte, the point is lowered and passed under the adversary's blade, which is pressed slightly outward, so as to be well covered (called "opposition"). "Double Engagement" is composed of two engagements executed rapidly in succession in the high lines, the last with opposition.

**Attack.**—The attack in fencing comprises all movements the object of which is to place the point of the foil upon the adversary's breast, body, sides or back, between collar and belt. The space upon which hits count is called the "target" and differs according to the rules prevailing in the several countries, but is usually as above stated. In Great Britain no hits above the collar-bones count, while in America the target is the left breast between the median line and the line running from the armpit to the belt. The reason for this limitation is to encourage accuracy.

Attacks are either "primary" or "secondary." **Primary Attacks** are those initiated by a fencer before his adversary has made any offensive movement, and are divided into "Simple," "Feint," and "Force" attacks.

**Simple Attacks,** the characteristic of which is pace, are those made with one simple movement only and are four in number, viz. the "Straight Lunge," the "Disengagement," the "Counter-disengagement" and the "Cut-over." The Straight-Lunge (coup droit), used when the adversary is not properly covered when on guard, is described above under "Lunge." The Disengagement is made by dropping the point of the foil under the opponent's blade and executing a straight lunge on the other side. It is often used to take an opponent unawares or when he presses unduly hard on your blade. The Counter-disengagement is used when the adversary wields his blade, i.e., changes the line of engagement, upon which you execute a narrow circle, avoiding his blade, and thrust in your original line. The Cut-over (coupé) is a disengagement executed by passing the point of the foil over that of the adversary and lunging in the opposite line. The preliminary movement of raising the point is made by the action of the hand only, the arm not being drawn back.

**Feint Attacks,** deceptive in character, are those which are preceded by one or more feints, or false thrusts made to lure the adversary into thinking them real ones. A feint is a simple extension, often with a slight movement of the body, threatening the adversary in a certain line, for the purpose of inducing him to parry on that side and thus leave the other open for the real thrust. At the same time any movement of the blade or any part of the body tending to deceive the adversary in regard to the nature of the attack about to follow, must also be considered a species of feint. The principal feint attacks are the "One-Two," the "One-Two-Three," the "Beat," and the "Double." The "One-Two" is a feint in one line, followed (as the adversary parries) by a thrust in the original line of engagement. Thus, being engaged in quarte, you drop your point under the adversary's blade and extend your arm as if to thrust at his left breast, but instead of doing this, the instant he parries you move your point back again and lung in quarte, i.e., on the side on which you were originally engaged. In feinting it is necessary that the extension of the arm and blade be so complete as really to compel the adversary to believe it a part of a real thrust in that line.

The "One-Two-Three" consists of two feints, one at each side, followed by a thrust in the line opposite to that of the original engagement. Thrusts preceded by three feints are also sometimes used. It is evident that the above attacks are useless if the adversary parries by a counter (circular parry), which must be met by a "Double." This is executed by feinting and, upon perceiving that the adversary opposes with a circular parry, by making the circle described by his point with a similar circle, deceiving (i.e., avoiding contact with) his blade and thrusting home.

The "Double," which is a favourite manoeuvre in fencing, is a combination of a disengagement and a counter-disengagement.

**Force-Attacks** are a class of parries, the object of which is to disconnect the opponent by striking his blade, are various in character, the principal ones being the "Beat," the "Press," the "Glide" and the "Bind." The "Beat" is a quick, sharp blow of the forte of the foil upon the blade of the adversary's, for the purpose of opening a way for a straight lunge which follows instantly. The blow is made with the hand only. A "false beat" is a lighter blow made for the purpose of drawing out or disconnecting the opponent, and is often followed by a disengagement. The "Press" is similar in character to the beat, but, instead of striking the adverse blade, a sudden pressure is brought to bear upon it, sufficiently heavy to force it aside and allow one's own blade to be thrust home. A "false press" may be used to entice the adversary into a too heavy responsive pressure, which may then be taken advantage of by a disengagement. The "Traverse" (Fr. frottement, It. striscie) is a prolonged press carried sharply down the adverse blade towards the handle. The "Glide" ("Grazie," Fr. coude) is a stealthy sliding of one's blade down that of the adversary, without his notice, until a straight thrust can be made inside his guard. It is also used as a feint before a disengage. The "Bind" (lenuent) consists in gaining possession of the adversary's foil with one's forte, and pressing it down and across into the opposite low line, when one's own point is thrust home, the adversary's blade being still held by one's hilt. It may be
FOIL-FENCING

also carried out from a low line into a high one. The bind is less used in the French school than in the Italian. The "Flan-
connade" is a bind made by capturing the adversary's blade in high quarter, carrying it down and thrusting in the outside
line with strong opposition. Another attack carried out by
means of a twist and thrust is the "Cross" (croisé) which is
executed when the adversary's blade is held low by passing one's
point over his wrist and forcing down both blades into seconds
with a full extension of the arm. The result is to create a sudden
and wide opening, and often disarms the adversary.

Secondary Attacks are those made (1) just as your adversary
himself starts to attack; (2) during his attack; and (3) on the
completion of his attack if it fails.

1. "Attacks on the Preparatory" are a matter of judgment
and quickness. They are usually attempted when the adversary
is evidently preparing a complicated attack, such as the "op-
two-three" or some other maneuver, involving one or more
preliminary movements. At such a time a quick thrust will
often catch him unawares and score. Opportunities for pre-
paration attacks are often given when the adversary attempts
a beat preliminary to his thrust; the beat is frustrated by an
"absence of the blade," i.e. your blade is made to avoid contact
with his by a narrow movement, and your point thrust home into the space left unguarded by the force of
his unresisted beat. Or the adversary himself may create an
"absence" by suddenly interrupting the contact of the blades, in
which case the removal of your blade before it has fully
flown off to one side, leaving an opening; if, however, you are
prepared for his "absence" a straight thrust will score.

2. The chief "Attacks on the Development," or "Counter
Attacks," are the "Stop Thrust" and the "Time Thrust,"
both made while the adversary is carrying out his own attack.
The "Stop Thrust" (coup d'arrêt) is one made after the adver-
sary has actually begun an attack involving two or more move-
ments, and is only justified when it can be brought off without
your being hit by the attacking adversary's point on any part of
the person. The reason for this is, that the rules of fencing decree
that the fencer attacked must parry, and that, if he disregards this
and attempts a simultaneous counter attack, he must touch his
opponent while totally avoiding the latter's point. Should he,
however, be touched, even on the foot or mask, by the adversary,
his touch, however good, is invalid. If both touches are good,
that of the original attacker, only counts. Stop thrusts are
employed mostly against fencers who attack wildly or without
being properly covered. The "Time Thrust" is delivered with
opposition upon the adversary's composite attack (one involving
several movements), and, if successful, generally parries the
original adversary's attack at the same time. It is not valid if the fencer
employing it is touched on any part of the person.

3. "Attacks on the Completion" (i.e. of the adversary's
attack) are "Ripostes," "Counter-ripostes," "Remises" and
"Renewals of Attack."

The Riposte (literally, response) is an attack made, immediately
after parrying successfully, by merely straightening the arm,
the body remaining immovable. The "counter-riposte" is a
riposte made after parrying the adversary's riposte, and gener-
ally involves the use of the lunges, which are received freely,
since one must have attacked with a full lung if the adversary
has had an opportunity to deliver a riposte. There are three
types of ripostes: direct, withfeints and after a pause.

The "direct riposte" may be made instantly after parrying
the adversary's thrust by quipping his blade and straightening
the arm, so that the point will touch his body on the nearest
and most exposed part; or by not quipping his blade but running
yourself quickly down his and at the same time keeping a strong
opposition ("riposte d'opposition"). The quickest direct riposte is
the "Monjou," executed after parrying quarter (for a right-hand fencer),
and is called by the French the riposte of "tac-au-tac," imitative
of the sudden succession of the click of the parry and the tap of
the riposting fencer's point on his adversary's breast. In making
"ripostes with a feint" the point is not jabbed on to the op-
ponent's breast immediately after the parry, but one or more
preliminary movements precede the actual riposte, such as a
disengagement, a cut-over or a double.

Ripostes with a pause (d temps perdu, with lost time) are made
after a second's hesitation, and are resorted to when the fencers
are too near for an accurate direct riposte, or to give the
advantage of time to make a quick parry, which is then received.

The remise is a thrust made after one's first thrust has been
parried and in the same line; it must be made in such a way
that the adversary's justified riposte is at the same time parried
by opposition or completely avoided. It is really a renewal of
the attack in the original line, while the so-called "renewal of
attack" ("redoublement d'attaque") is a second thrust which
ignores the adversary's riposte, but made in a different line.
Both the remise and the renewal are valid only when the
adversary's riposte does not hit.

False Attacks are broad movements made for the purpose
of drawing the adversary out or of disconcerting him. They
may consist of an advance, an extension, a change of engage-
ment, an intentional uncovering by taking a wide guard (called
"invitation guard"), or any movement or combination of
movements tending to make the adversary believe that a real
attack is under way.

The Assault is a formal fencing bout or series of bouts in public,
while formal fencing in private is called "loose play" or a "friendly
bout.

Bouts between fencers take place on a platform about 24 ft. long and 6 ft. wide (in the United States
20 ft. by 6 ft.). Fencing may continue for a certain number of minutes, the fencer who touches
oftenest winning. The judges (usually three or five) are some-
times empowered to score one or more points against a com-
petitor for breaches of good form, or for overstepping the space
limits. In the United States bouts are for four minutes, with
a change of places after two minutes, and the competitors are
not interrupted, the winner being indicated by a vote of the
judges, who take into account touches and style. In all countries
contestants are required to wear jackets of a light colour, so
that they may be distinguished if hit. A fencer may be touched,whether on the target or not, is universally considered to be a
fencer's duty. Fencing competitions are held in Great
Britain under the rules of the Amateur Fencing Association,
and in the United States under those of the Amateur Fencers'
League of America.

Fencing Terms (not mentioned above): "Casarone," Ital. for
disengagement. Contraction. Parries of, those which do not parry in
removing the adversary's blade; a parry may remove the adversary's blade into a bad line, e.g. to carry a thrust in high sext by counter of quart. "Contrallegare," Ital. for time-thrust. "Coronation," an attack preceded by a circular movement from high quarter to high quart (and vice versa) in the adversary's circle, called "entry" or "regate," means the body, the position of two fencers who are at such close quarters that their persons touch; when this occurs the fencers must again become "solo," Fr. for glide. "D'arrêter," to knock off the
foil out of the adversary's hand; it is of no value in the French
school. "Double Hit," when both fencers attack and hit at the same
time; neither hit counts. "File," Ital. for glide (graze). "Flying Cut-over," a cut-over executed as a continuation of a
parry, the hand being drawn back towards the body. "Incontro," Ital. for double attack. "Give the blade," to allow the adversary
easy contact with the foil. It is often resorted to in order to tempt
the adversary into a beat or bind. "Menace," to threaten the adversary by an extension and forward movement of the trunk.
attacks and parries ending in a hit or invalidation. "Invalidation," a hit on some part of the person outside the target, made by the fencer
whose right it is at that moment to attack or riposte; such a hit
validates one made simultaneously or sequentially by his opponent; however good. "Rebut," two beats, executed as quickly as possible
together, one on each side of the adversary's blade. "Reprises," Fr. for "salute." "Stop," an attack which, by the salutation of the public and the adversary before and after a bout.
A more elaborate salute, called by the French the Mur, consists of a series of parries, lunges and other evolutions carried out by both
parties in exactly the same time, an important element in successful attacks are usually preceded by the Mur, which is called in English the Grand Salute. "Septime enveloppée," a riposte by means of a twist and thrust after a parry in septime. "Spécial," Fr. for glide and "Point" and "But" (called "Secret thrusts," the French "bâton serré").

Pretended infallible attacks of which the user is supposed alone to
know the method of execution; they have no real existence.

"Toccati" (Hitam) for "Touché!!" French.

BIBLIOGRAPHY.—The literature of foil-fencing is practically identical with that of the art in general (see FENCING). The following modern writers are among the French who have published on the subject: Fencing in the Badminton library (1897); Foil and Sabre, by L. Brondelle (Boston, 1892); "Fencing," by C. Prevost in the Encyclopædia of Sport (1901); Fencing, by Edward Bridg (New York, 1906). Italian school: Estruscan per la scherma, etc., by S. Toccata (Milan, 1885); La Scherma Italiana di spada e di sciabola, by F. Masiello (Florence, 1887).

FOIX, PAUL DE (1528-1584), French prelate and diplomatist. He studied Greek and Roman literature at Paris, and jurisprudence at Toulouse, where shortly after finishing his curriculum he delivered a course of lectures on civil law, which gained him great reputation. At the age of nineteen he was named councillor of the parlement of Paris. Having in this capacity expressed himself favourable to the adoption of mild measures in regard to certain persons accused of Lutheranism, he was arrested, but escaped punishment, and subsequently regained the favour of the French court. At the end of 1561 he was sent ambassador to England, where he remained four years. He was then sent to Venice, and returned a short time afterwards to England to negotiate a marriage between Queen Elizabeth and the duke of Anjou. He again fulfilled several important missions during the next six years. In 1571, he was made archbishop of Toulouse, and in 1579 was appointed ambassadoer to Rome, where he remained till his death in 1584.

Les Lettres de Messeire de Paul de Foix, archevêque de Toulouse et ambassadeur pour le roy apres le pape Grégoire XIII, au roi Henri III, were published in 1628, but there are some doubts as to their authenticity. — See Galatea Christiana (1715 seq.); M. A. Muret, Oraison funèbre de Paul de Foix (Paris, 1858); "Les Lettres de Catherine de Médicis," edited by Hector de la Ferrière (Paris, 1850 seq.) in the Collection de documents inédits sur l'histoire de France.

FOIX, a town of south-western France, in the middle ages capital of the counts of Foix, and now capital of the department of Ariège, 51 m. S. of Toulouse, on the Southern railway from that city to Ax. Pop. (1906) town, 4495; commune, 6750. It is situated between the Ariège and the Arget at their confluence. The old part of the town, with its ill-paved winding streets and old houses, is dominated on the west by an isolated rock crowned by the three towers of the castle (12th, 14th, and 15th centuries), while to the south it is limited by the shady Promenade de Villette. The chief church is that of St Vulsonis, a Gothic building of the 14th century. The town is the seat of a prefecture, a court of assizes and a tribunal of first instance, and has a lycée, training colleges, a chamber of commerce and a branch of the Bank of France. Flour-milling and iron-working are carried on. Foix probably owes its origin to an oratory founded by Chartres. This afterwards became an abbey, in which were laid the remains of St Vulsonis, archbishop of Tours in the 5th century.

The county of Foix included roughly the eastern part of the modern department of Ariège, a region watered chiefly by the Ariège and its affluent. During the later middle ages it consisted of an agglomeration of small holdings ruled by lords, who, though subordinate to the counts of Foix, had marked the old feudal family. In the 13th and 14th centuries the Protestant heretics obtained an early entrance into the country, and the religious struggles of the 16th and 17th centuries were carried on with much implacability therein. The estates of the country, which can be traced back to the 14th century, consisted of three orders and possessed considerable power and vitality. In the 17th and 18th centuries Foix formed one of the thirty-three governments of France, and in 1790 it was incorporated in the department of Ariège.

Counts of Foix.—The counts of Foix were an old and distinguished French family, which derived its origin from the 11th to the 12th centuries. They were at first feudatories of the counts of Toulouse, but chafing under this yoke they soon succeeded in throwing it off, and during the 13th and 14th centuries were among the most powerful of the French feudal nobles. Living on the borders of France, having constant intercourse with Navarre, and in frequent communication with England, they were in a position peculiarly favourable to an assertion of independence, and acted rather as the equals than as the dependents of the kings of France.

The title of count of Foix was first assumed by Roger, son of Bernard Roger, who was a younger son of Roger I., count of Carcassonne (d. 1012), when he inherited the town of Foix and the adjoining lands, which had hitherto formed part of the county of Carcassonne. Dying about 1044, Roger was succeeded by his brother Peter, who died six years later, and was succeeded in turn by his son, Roger II. This count took part in the crusade of 1095, and was afterwards excommunicated by Pope Paschal II. for seizing ecclesiastical property; but subsequently he appeased the anger of the church by rich donations, and when he died in 1125 he was succeeded by his son, Roger III. The death of Roger III. about 1149, and of his son, Roger Bernard I., in 1188, brought the county to Roger Bernard's only son, Raymond Roger, who, in 1190, accompanied the French king, Philip Augustus, to Palestine and distinguished himself at the capture of Acre. He was afterwards engaged in the wars of the Albigensians, and on being accused of heresy his lands were given to Simon IV., count of Montfort. Raymond Roger, who came to terms with the church and recovered his estates before his death in 1273, was a patron of the Provencal poets, and counted himself among their number. He was succeeded by his son, Roger Bernard II., called the Great, who assisted Raymond VII., count of Toulouse, and the Albigensians in their resistance to the French kings, Louis VIII. and Louis IX., was excommunicated on two occasions and died in 1291. His son, Roger IV., who followed, died in 1265, and was succeeded by his son, Roger Bernard III., who, more famous as a poet than as a warrior, was taken prisoner both by Philip III. of France and by Peter III. of Aragon. This count married Marguerite, daughter and heiress of Gaston VII., viscount of Béarn (d. 1290), and this union led to the outbreak of a long feud between the houses of Foix and Armagnac; a quarrel which was continued by Roger Bernard's son and successor, Gaston I., who became count in 1302, inheriting both Foix and Béarn. Becoming embroiled with the French king, Philip IV., in consequence of the struggle with the count of Armagnac, Gaston was imprisoned in Paris; but quickly regaining his freedom he accompanied King Louis X. on an expedition into Flanders in 1315, and died on his return to France in the same year. His eldest son, Gaston II., was the next count. Having become reconciled with the house of Armagnac, Gaston took part in various wars both in France and Spain, dying at Seville in 1343, when he was succeeded by his son, Gaston III. (1331-1351). Gaston III., who was succeeded by his own son, was the last representative of the branch of the old Foix family. Like his father he assisted France in her struggle against England, being entrusted with the defence of the frontiers of Gascony; but when the French king, John II., showed a marked preference for the count of Armagnac, Gaston left his service and went to fight against the heathen in Prussia.

Returning to France about 1357 he delivered some noble ladies from the attacks of the adherents of the Jacquerie at Meaux, and was soon at war with the count of Armagnac. During this struggle he was joined by the English king, Edward III., who invaded Languedoc, but owing to the intervention of Pope Innocent VI. he made peace with the count in 1360. Gaston, however, continued to fight against the count of Armagnac, who, in 1362, was defeated and compelled to pay a ransom; and this war lasted until 1377, when peace was made. Early in 1380 the count was appointed governor of Languedoc, but when Charles VI. succeeded Charles V. as king in the same year, this appointment was cancelled. Refusing, however, to heed the royal command, and supported by the counts of Foix, another Gaston fought for about two years against John, duke of Berry, who had been chosen as his successor, until, worsted in the combat, he abandoned the struggle and retired to his estates, remaining neutral and independent. In 1348 the count had married Agnes, daughter of Philip, count of Evreux (d. 1345), by his wife Jeanne II., queen of Navarre. By Agnes, whom he
divorced in 1373, he had an only son, Gaston, who is said to have been incited by his uncle, Charles II, king of Navarre, to poison his father, and who met his death in 1381. It is probable, as Froissart says, that he was killed by his father. Left without legitimate sons, Gaston was easily persuaded to bequeath his large inheritance and the kingdom of Navarre to his half-brother Jean, on the condition that he assume the name of Foix-Grailly, for which he was subsequently made Viscount of Foix when the count died at Orthes in 1392. Gaston was very fond of hunting, but was not without a taste for art and literature. Several beautiful manuscripts are in existence which were executed by his orders, and he himself wrote *Dévoués de la chasse des bestes sauvages et des oiseaux de proye*. Froissart, who gives a graphic description of his court and his manner of life, speaks enthusiastically of Gaston, saying: "I never saw none like him of personage, nor of so fair form, nor so well made," and again, "in everything he was so perfect that he cannot be praised too much.""

Almost immediately after Gaston's death King Charles VI. granted the county of Foix to Matthew, viscount of Castelbon, a descendant of Count Gaston I. Dying without issue in 1398, Matthew's lands were seized by Ambarchambault, count of Grailly and capitul de Buch, the husband of his sister Isabella (d.1426), who became count of Foix in 1401. Ambarchambault's eldest son, John (c. 1382-1436), who succeeded to his father's lands and titles in 1412, married in 1402 Jeanne, daughter of Charles III, king of Navarre. Having served the king of France in Guienne, he was made a representative of Languedoc, and in 1398 was the royal representative in Languedoc, when the old quarrel between Foix and Armagnac broke out again. During the struggle between the Burgundians and the Armagnacs, he intrigued with both parties, and consequently was distrusted by the dauphin, afterwards King Charles VII. Deserting the cause of France, he then allied himself with Henry V. of England; but when Charles VII. became king in 1422, he returned to his former allegiance and became the king's representative in Languedoc and Guienne. He then assisted to suppress the marauding bands, which were devastating France; fought for Aragon against Castle; and aided his brother, the cardinal of Foix, to crush some insurgents in Aragon. Peter, cardinal of Foix (1386-1464), was the fifth son of Archambault of Grailly, and was made archbishop of Arles in 1450. He took a prominent part in the struggle between the rival popes, and founded and endowed the Collège de Foix at Toulouse. The next count was John's son, Gaston IV., who married Leonora (d. 1470), a daughter of John, king of Aragon and Navarre. In 1447 he bought the viscounty of Narbonne, and having assisted King Charles VII. in Guienne, he was made a peer of France in 1458. In 1455 his father-in-law deserted him as a dowry. In 1465 Louis XI. of France gave him the counties of Roussillon and Cerdaigne, and made him his representative in Languedoc and Guienne; but these marks of favour did not prevent him from joining a league against Louis in 1471. His eldest son, Gaston, the husband of Madeleine, a daughter of Charles VII. of France, died in 1470, and when Gaston IV. died two years later, his lands descended to his grandson, Francis Phoebeus (d. 1483), who became king of Navarre in 1479, and was succeeded by his sister Catherine (d. 1527), the wife of Jean d'Albret (d. 1516). Thus the house of Foix-Grailly was continued in that of the Counts of Foix, and subsequently in that of Bourbon; and when Henry of Navarre became king of France in 1589 the lands of the counts of Foix-Grailly became part of the French royal domain. A younger son of Count Gaston IV. was John (d. 1500), who received the viscounty of Narbonne from his father and married Marie, a sister of the French king Louis XII. He was on good terms both with Louis XI. and Louis XII., and on the death of his nephew Francis Phoebeus, in 1483, he claimed the kingdom of Navarre against Jean d'Albret and his wife, Catherine de Foix. The ensuing struggle lasted until 1497, when John renounced his claim. He left a son, Gaston de Foix (1490-1552), the distinguished French general, and a daughter, Germaine, who became the second wife of Ferdinand I., king of Spain. In 1507 Gaston exchanged his viscounty of Narbonne with King Louis XII. for the duchy of Nemours, and as Duke of Nemours he took command of the French troops in Italy. Having delivered Bologna and taken Brescia, Gaston encountered the troops of the Holy League at Ravenna in April 1512, and after putting the enemy to flight was killed during the pursuit. From the younger branch of the house of Foix-Grailly have also sprung several persons of note, including the counts of Béarn and the counts of Foix, and of Guisan and Liege.

**FOLARD, JEAN CHARLES, CHEVALIER DE (1609-1752),** French soldier and military author, was born at Avignon on the 13th of February 1609. His military ardor was underlain by reading Caesar’s *Commentaries*, and he ran away from home and joined the army. He soon saw active service, and, young as he was, wrote a manual on partisan warfare, the manuscript of which passed with Folard’s other papers to Marshal Belleisle on the author’s death. In 1702 he became a captain, and aide-de-camp to the duke of Vendôme, then in command of the French forces in Italy. In 1705, when serving under Vendôme’s brother, the Grand Prior, Folard won the cross of St Louis for a gallant feat of arms, and in the same year he distinguished himself at the battle of Cassano, where he was severely wounded. It was during this tedious recovery from his wounds that he conceived the tactical theories to the elucidation of which he devoted most of his life. In 1706 he again rendered good service in Italy, and in 1708 distinguished himself greatly in the operations attempted by Vendôme and the duke of Burgundy for the relief of Lille, the failure of which was due in part to the disagreement of the French commanders; and it is no small testimony to the ability and tact of Folard that he retained the friendship of both. Folard was wounded at Malplaquet in 1706, and in 1711 he served in Flanders and was rewarded with the governorship of Bourbourg. He saw further active service in 1714 in Malta, where Charles XII. of Sweden in the north, and under the duke of Berwick in the short Spanish War of 1719. Charles XII. he regarded as the first captain of all time, and it was at Stockholm that Folard began to formulate his tactical ideas in a commentary on Polybius. On his way back to France he was shipwrecked and lost all his papers, but he set to work at once to write his essays afresh, and in 1724 appeared his *Nouvelles Découvertes sur la guerre dans une dissertation de Polybe*, followed (1727-1728) by *Histoire du siège de Bologna*, while a second commentary upon *M. de Folard, Chevalier de l’Ordre de St Louis*. Folard spent the remainder of his life in answering the criticisms provoked by the novelty of his theories. He died friendless and in obscurity at Avignon in 1752.

An analysis of Folard’s military writings brings to light not a connected theory of war as a whole, but a great number of independent ideas, sometimes valuable and suggestive, but far more often extravagant. The central point of his tactics was his proposed column formation for infantry. Struck by the apparent weakness of the thin line of battle of the time, and borrowing from the *sphæroïdes* or cænets of ancient times, he desired to substitute the shock of a deep mass of troops for former methods of attack, and further considered that in defence a solid column gave an unshakable stability to the line of battle. Controversy at once centred itself upon the column. Whilst some famous commanders, such as Marshal Saxe and Guido Starhemberg, approved it and put it in practice, the weight of military opinion throughout Europe was opposed to it, and eventually history justified this opposition. Amongst the most devastating of his critics was Frederick the Great, who is said to have invited Folard to Berlin. The Prussian king certainly caused a précis to be made by Colonel von Seers, and wrote a preface thereto expressing his views. The work (like others by Frederick) fell into unauthorized hands, and, on its publication (Paris, 1760) under the title *Esprit du Chev. Folard*, created a great impression. “Thus kept within bounds,” said
the prince de Ligne, "Folard was the best author of the time."
Frederick himself said tersely that "Folard had buried diamonds in a
rubbish-heap." Thus began the controversy between line
and column formations, which long continued and
influenced the development of tactics up to the most modern times.
Folard's principal adherents in the 18th century were Joly de Malzeroy
and Menil Durand.

See Mém. pour servir à l'histoire de M. le Chevalier de Folard
(Paris and Regensburg, 1753), and for a detailed account of Folard's
works and those of his critics and supporters, Max Jähns, Geschichte der
Kriegswissenschaften, vol. ii. pp. 1478-1493 (Munich and Leipzig,
1890).

FOLD, a pleat or bend in a flexible material, or a curve in any
surface, whence its particular application in geology with which
this article deals. The verb "to fold" (O. Eng. foldan) meant
originally to double back a piece of cloth or other material as to
form a pleat, whence has evolved its various senses of to roll
up, to enclose, enfold or embrace as with the arms, to clasp the
hands or arms together, &c. The word is common to Teutonic
languages, cf. Ger. falten, Dutch vouwen (for vouden), &c., and
the ultimate Indo-European root is found in Gr. ἔκλεισθαι,
Lat. plieare, plicare, to plait, pleat, weave, and in the suffixes of such
words as Latin duplex, double, simplex, &c. Similarly the
termination "fold" is added to numbers implying "so many,"
e.g. twofold, hundredfold, cf. "unifold." The similar word
for an enclosure or pen for animals, especially for sheep, and
hence applied in a spiritual sense to a community of worshippers,
or to the whole body of Christians regarded as Christ's flock,
must be distinguished. In O. Eng. it is fald, and cognate forms
are found in Dutch vaalt, &c. It apparently meant a planked or

In geology, a fold is a bend or curvature in the stratified
rocks of the earth's crust, whereby they have been made
to take up less horizontal space. The French equivalents are
pli, plissement, rideau; in Germany, Falte, Fallung, Setzung
are the terms usually employed. It is comparatively rarely that
bedded rocks are observed in the position in which they were
first deposited, a certain amount of buckling up or sagging down
of the crust being continually in progress in one region or another.
In every instance therefore where, in walking over the surface,
we traverse a series of strata which gradually, and without dis-
locations, increase or diminish in inclination, we cross part of a
great curvature in the strata of the earth's crust.

Such foldings, however, can often be distinctly seen, either on
some cliff or coast-line, or in the traverse of a piece of hilly or
mountainous ground. The observer cannot long continue his
researches in the field without discovering that the rocks of the
earth's crust have been almost everywhere thrown into curves,
usually so broad and gentle as to escape observation except
when specially looked for. The outcrop of beds at the surface
is commonly the truncation of these curves. The strata must
once have risen above the present surface, and in many cases
may be found descending to the surface again with a contrary dip,
the intervening portion of the undulation having been worn away.

The curvature occasionally shows itself among horizontal or
gently inclined strata in the form of an abrupt inclination, and
then an immediate resumption of the previous flat or sloping
character. The strata are thus bent up and continue on the other
side of the tilt at a higher level. Such bends are called mono-
clines, monoclinal folds or flexures, because they present only one
fold, or one half of a fold, instead of the two which we see in an
arch or trough. The most notable instance of this structure in
Britain is that of the Isle of Wight, of which a section is given in
fig. 1. The Cretaceous rocks on the south side of the island
rapidly rise in inclination till they become nearly vertical.

The Lower Tertiary strata follow with a similar steep dip, but
rapidly flatten down towards the north coast. Some remarkable
cases of the same structure have been brought to light by J. W.
Powell in his survey of the Colorado region.

It much more frequently happens that the strata have been
bent into arches and troughs, so that they can be seen dipping
down the surface on one side of the axis of a fold, and rising up
again on the other side. Where they dip away from the axis of
movement the structure is termed an anticline or monoclinal fold;
where they dip towards the axis, it is a syncline or synclinal fold.
The diagram in fig. 2 may be taken to represent a series of strata

(1-17) thrown into an anticline (AA') and syncline (BB'). A
section drawn across these folds in the line CD would show
the structure given in fig. 3. Here we see that, at the part of the

Fig. 3.—Section on line C D.
sides of an anticline or syncline are known as the "limbs," "slopes," "flanks" or "members" of the fold; in an anticline, the part X, fig. 3, the angle of the bend, is the "crest" or "crown" (Ger. Gewölbeebiegung, Fr. charnière antichinale), the corresponding part of a syncline being the "trough-core" or "base," Y, fig. 3 (Ger. Muldenbiegung, Fr. charnière synclinales). The portion of an anticline which has been removed by denudation is the "axial arch," dotted in fig. 3. The innermost strata in a fold constitute the "core," arch-core A, fig. 3, or trough-core B, in the same figure. In the majority of folds the bend of the strata has taken place about an "axial plane" (often called the "axis"), which in the examples illustrated in fig. 3 would pass through the points A and B, perpendicularly to the horizontal line CD. In powerfully folded regions the axial planes of the folds are no longer upright; they may be moderately inclined, producing an "inversion," or "overfold." When the inclination of the axial plane is great a "recumbent overfold" is produced (Fr. pli couché, Ger. liegende Falte). In a fold of this kind (fig. 4) we have an "arch limb" (a), a middle limb (b) and a floor or "trough limb" (c). X and Y are the upper and lower bends respectively.

One of the important functions of a fold is its direction; this of course depends upon the orientation of the axial plane. An anticline or trough-line of a syncline is rarely horizontal for any great distance; its departure from horizontality is designated the "pitch," and the fold is said to pitch (or dip) towards the north, &c. Most simple folds—with the exception of very shallow curvatures of wide area,—when considered in their entirety, are seen to be somewhat canoe-shaped in form. There are three variations of the simple fold dependent upon the position of the limbs, (1) the limbs may tend to diverge as they recede from the crest (fig. 3), sometimes styled an "open anticlinal," (2) the limbs may be parallel in "closed" folds (commonly known as isoclinal folding); (3) the limbs may make an open angle or widen out towards the crest (fig. 4). This is known as a fan-shaped fold (Fr. pli en éventail, Ger. Fächerfalte); another variant of the same form is the mushroom fold (Fr. pli en champignon). The axial plane is not always extended: it may be so abbreviated that the folding appears to have taken place about a point; anticlines of this type are variously designated "short-anticlines," "brachyanticlinus" or "dome"; similarly, there are "short-synclines" or "brachysynclinales"; (4) the folds may be highly complex in regions of extreme crustal movement, and may contain smaller folds of the first, second, third or higher order (Fr. couche sautée, fig. 5). In its smaller manifestation, this class of folding passes into "crumpling" or "puckering," where quite a large number of folds may be crowded into a single hand specimen. In "frilling" or "frilled structure" the folds have still smaller amplitude, and in many highly corrugated rocks minute folds are observable with the microscope that do not appear to the unaided eye. When a series of adjacent iso- clinal overfolds has passed into a series of thrusts (see Faults), the so-called "imbricated" structure (Fr. structure imbriquée, Ger. Schuppentracht) is generated. Occasionally crust-blocks resembling "graben" and "horsts" are circumscribed by folds instead of faults; when this is so they have been called respectively "infolded graben" or "overfolded horsts."

The heterogeneous character of great masses of strata has always had a marked influence on the nature of the folding; some beds have yielded much more readily than others, certain beds will be found to be faulted, while those above and below have folded without fracture. In many examples of apparent plasticity it can be shown that this effect has been produced by an infinite number of minute slipings within the rock substance.

The larger rock folds have produced important economic results. For example, in many coal regions the deposits have been preserved in some districts in the synclines or "basins," while they have been removed by denudation from the uplifted anticlines in others. Near the crest of anticlines is commonly an enriched portion of the ground in mineralized districts; and, in the case of water supply, the tilt of the strata determines the direction of the underground flowage. Again, the most convenient site for oil wells is the crest of an anticline or "dome," where an impervious stratum imprisons the gas and oil in a subjacent saturated layer under pressure.

For a discussion of the question of the distribution and arrangement of the great folded regions of the earth's crust, see E. Sues, Das AntiKle der Erde, English translation, The Face of the Earth, vols. i., ii., iv. (Oxford). See also E. de Margerie and A. Heim, Les Dissolutions de l'écorce terrestre (Zurich, 1888); A. Rothpletz, Geotektonische Probleme (Stuttgart, 1894).

FOLENGO, TEOFILO (1401-1544), otherwise known as Merlino Cocajo or Cocajo, one of the principal Italian macaronic poets, was born of noble parentage at Cipada near Mantua on the 8th of November 1491. From his infancy he showed great vivacity of mind, and a remarkable cleverness in making verses. At the age of sixteen he entered the monastery of Monte Casino near Brescia, and eighteen months afterwards he became a professed member of the Benedictine order. For a few years his life as a monk seems to have been tolerably regular, and he is said to have produced a considerable quantity of Latin verse, written, not unsuccessfully, in the Virgilian style. About the year 1536 he forsook the monastic life for the society of a well-born young woman named Girolama Dieda, with whom he wandered about the country for several years, often suffering great poverty, having no other means of support than his talent for versification. His first publication was the Merlini Cocati macaronicon, which relates the adventures of a fictitious hero named Baldus. The coarse buffoonery of this work is often relieved by touches of genuine poetry, as well as by graphic descriptions and acute criticisms of men and manners. Its macaronic style is rendered peculiarly perplexing to the foreigner by the frequent introduction of words and phrases from the Mantuan patois. Though frequently censured for its occasional grossness of idea and expression, it soon attained a wide popularity, and within a very few years passed through several editions. Folengo's next production was the Orlandino, an Italian poem of eight cantos, written in rhymed octaves. It appeared in 1536, and bore on the title-page the new pseudonym of Lermos Pitocchio (Merlin the Beggar) da Mantova. In the same year, wearied with a life of dissipation, Folengo returned to his ecclesiastical obedience; and shortly afterwards wrote his Chaos del tru per uno, in which, partly in prose, partly in verse, sometimes in Latin, sometimes in Italian, and sometimes in macaronic, he gives a veiled account of the vicissitudes of the life he had lived under his various names.
FOLEY, J. H.—FOLIO

599

FOLEY, JOHN HENRY (1818–1874), Irish sculptor, was born at Dublin on the 24th of May 1818. At thirteen he began to study drawing and modelling at the schools of the Royal Dublin Society, where he took several first-class prizes. In 1835 he was admitted a student in the schools of the Royal Academy, London. He first appeared as an exhibitor in 1836 with his "Death of Abel and Innocence." "Ino and Bacchus," exhibited in 1840, gave him immediate reputation, and the work itself was afterwards commissioned to be done in marble for the earl of Ellesmere. "Lear and Cordelia" and "Death of Lear" were exhibited in 1841. "Venus rescuing Aeneas" and "The Houseless Wanderer" in 1842, "Prospero and Miranda" in 1843. In 1844 Foley sent to the exhibition at Westminster Hall his "Goethe at a Stream," and was, with Calder Marshall and Bell, chosen by the commissioners to do work in sculpture for the decoration of the Houses of Parliament. Statues of John Hampden and Selden were executed for this purpose, and received liberal praise for the propriety, dignity and proportion of their treatment. Commissions of all kinds now began to come rapidly. Fanciful works, busts, bas-reliefs, tablets and monumental statues were in great numbers undertaken and executed by him with a steady equality of worthy treatment. In 1849 he was made an associate and in 1858 a member of the Royal Academy. Among his numerous works the following may be noticed, besides those mentioned above:—"The Mother"; "Egeria," for the Mansion House; "The Elder Brother in Comus," his diploma work; "The Muse of Painting," the monument of James Ward, R.A.; "Caraetacus," for the Mansion House; "Helen Fauci"; "Goldsmith" and "Burke," for Trinity College, Dublin; "Faraday"; "Reynolds"; "Barry," for Westminster Palace Yard; "John Stuart Mill," for the Thames embankment; "O’Connell" and "Gough," for Dublin; "Clyde," for Glasgow; "Clive," for Shrewsbury; "Hardinge," "Canning" and "Outram," for Calcutta; "Hon. James Stewart," for Ceylon; the symbolic group "Asia," as well as the statue of the prince himself, for the Albert Memorial in Hyde Park; and "Stonewall Jackson," in Richmond, Va. The statue of Sir James Outram is probably his masterpiece. Foley’s early fanciful works have some charming qualities; but he will probably always be best remembered for the workmanlike and manly style of his monumental portraits. He died at Hampstead on the 27th of August 1874, and on the 4th of September was buried in St Paul’s Cathedral. He left his models to the Royal Dublin Society, his early school, and a great part of his property to the Artists’ Benevolent Fund.

FOLEY, SIR THOMAS (1757–1833), British admiral, entered the navy in 1770, and, during his time as midshipman, saw a good deal of active service in the West Indies against American privateers. Promoted lieutenant in 1778, he served under Admiral (afterwards Viscount) Keppel and Sir Charles Watson at Lagos, on the Guinea coast, in the Channel, and with Rodney’s squadron was present at the defeat of De Langle off Cape Francois in 1779, and at the relief of Gibraltar. Still under Rodney’s command, he went out to the West Indies, and took part in the operations which culminated in the victory of the 12th of April 1782. In the Revolutionary War he was engaged from the first. As flag-captain to Admiral John Gell, and afterwards to Sir Hyde Parker, Foley took part in the siege of Toulon in 1793, the action of Golfe Junan in 1794, and the two fights off Toulon on the 13th of April and the 13th of July 1795. At St Vincent he was flag-captain to the second in command, and in the following year was sent out in command of the "Goliath" (74), to reinforce Nelson’s fleet in the Mediterranean. The part played by the "Goliath" in the battle of the Nile was brilliant. She led the squadron round the French van, and this manoeuvre contributed not a little to the result of the day. Whether this was done by Foley’s own initiative, or intended by Nelson, has been a matter of controversy (see Journal of the Royal United Service Institution, 1885, p. 916). His next important service was with Nelson in the Baltic. The "Elephant" carried Nelson’s flag at the battle of Copenhagen, and her captain acted as his chief-of-staff. Ill-health obliged Foley to decline Nelson’s offer (made when on the point of starting for the battle of Trafalgar) of the post of Captain of the Fleet. From 1808 to 1815 he commanded in the Downs and at the peace was made K.C.B. Sir Thomas Foley rose to be full admiral and G. C. B. He died while commanding in chief at Portsmouth in 1813.

See J. B. Herbert, Life and Services of Sir Thomas Foley (Cardiff, 1884).

FOLI (FOLEY), ALLAN JAMES (1837–1890), Irish bass singer, was born at Cahir, Tipperary, on the 7th of August 1837; originally a carpenter, he studied under Bisaccia at Naples, and made his first appearance at Catania in 1862. From the opera in Paris he was engaged by Mapleson for the season of 1865, and again for the season of 1866. He sang in the first performance of The Flying Dutchman (Daland) in England in 1870, and in the first performance of Gounod’s Redemption in 1882. He was distinguished in opera and oratorio alike for his vigorous, straightforward way of singing, and was in great request at ball concerts. He died on the 20th of October 1890.

POLIGNO (anc. Foligno, q.v.), a town and episcopal see of Umbria, Italy, 771 ft. above sea-level, in the province of Perugia, from which it is 25 m. S.E. by rail. Pop. (1901) 9532 (town), 26,978 (commune). It lies in a fertile plain, on the Topino, a tributary of the Tiber; it is almost square in shape and is surrounded by walls. It is a picturesque and interesting town; several of its churches contain paintings by Umbrian masters, notably works by Nicolò di Liberto (or Nicolò Alunno, 1430–1502), and among them his chief work, a large altar-piece (the predella of which is in the Louvre) in S. Niccolò. The cathedral has a romaneseque S. façade of 1133, restored in 1903; the interior was modernized in the 18th century. To the left of the altar is an in Gattamelata and Antonio da Sangallo the younger (1527). In the same piazza as the S. façade is the Palazzo del Governo, erected in 1350, which has a chapel with frescoes by Ottaviano Nelli of Gubbio (1424). S. Maria infra Portas is said to date from the 7th century, but from this period only the columns of the portico remain. Raphael’s "Madonna di Foligno," now in the Vatican, was originally painted for the church of S. Anna. The Palazzo Orfini and the Palazzo Deli are two good Renaissance buildings.

Foligno seems to have been founded about the middle of the 8th century A.D. It changed hands often during the wars of the 13th century, and was destroyed by Perugia in 1281. From 1305 to 1439 it was governed by the family of the Trinci as deputies of the Holy See, until in the latter year one of its members went against the church. Pope Eugen IV. sent a force against Foligno, to which the inhabitants opened their gates, and the last of the Trinci, Corrado II., was beheaded. Henceforth Foligno belonged to the states of the church until 1860. It suffered from a severe earthquake in 1852. Foligno is a station main line from Rome (via Ortona) to Ancona, and is the junction for Perugia. Three miles to the E. is the abbey of Sassovivo with cloisters of 1220, very like those of S. Paolo fuori le Mura at Rome, with pairs of small columns supporting arches, and decorations in coloured mosaic ("Cosmatesque" work). The church has been modernized.

FOLIO (properly the ablative case of the Lat. folium, leaf, but also frequently an adaptation of the Ital. foglio), a term in
bibliography and printing, with reference either to the size of paper employed, or of the book, or to the pagination. In the phrase "in folio" it means a sheet of paper folded once, and thus a book bound up in sheets thus folded is a book of the largest size and is known as a "folio" (see Bibliography). Similarly, "folio" is one of the sizes of paper adapted to be thus folded (see paper). In book-keeping the word is used for a page in a ledger on which the credit and debit account is written; in law-writing, for a fixed number of words in a legal document, used for measurement of the length and for the addition of costs. In Great Britain, a "folio" is taken to contain 72 words, except in parliamentary and chancery documents, when the number is 90. In the U.S.A. 100 words form a "folio".

FOLIUM, in mathematics, a curve invented and discussed by René Descartes. Its cartesian equation is \( y^2 + x^2 = axy + b^2x \). The curve is symmetrical about the line \( y = x \), and consists of two infinite branches asymptotic to the line \( y = \frac{1}{2}x \) and a loop in the first quadrant. It may be traced by giving \( m \) various values in the equations \( x = \frac{2m}{m^2 - 1} \), \( y = \frac{2m}{m^2 - 1} \), since by eliminating \( m \) between these relations the equation to the curve is obtained. Hence it is unicusural (see Curve). The area of the loop, which equals the area between the curve and its asymptote, is \( \frac{\pi}{2} \).

FOLKES, MARTIN (1600-1754), English antiquary, was born in London on the 20th of October 1600. He was educated at Saumur University and Clare College, Cambridge, where he so distinguished himself in mathematics that when only twenty-three years of age he was chosen a fellow of the Royal Society. He was elected one of the council in 1716, and in 1723 Sir Isaac Newton, president of the society, appointed him one of the vice-presidents. On the death of Newton he became a candidate for the presidency, but was defeated by Sir Hans Sloane, whom, however, he succeeded in 1741; in 1742 he was made a member of the French Academy; in 1746 he received honorary degrees from Oxford and Cambridge. In 1753 he set out on a tour through Italy, in the course of which he composed his Dissertations on the Weights and Values of Ancient Coins. Before the Society of Antiquaries, of which he was president from 1740 to 1754, he read in 1736 his Observations on the Trojan and Antoinine Pillars at Rome and his Table of English Gold Coins from the 13th Year of King Edward III. In 1745 he printed the latter with another on the history of silver coinage. He also contributed both to the Society of Antiquaries and to the Royal Society other papers, chiefly on Roman antiquities, which were published in 1714 Lucretia Bradshaw, an actress who had appeared at the Haymarket and Drury Lane (see Nicholls's Litt. Anecdot. ii. 578-598).

For Sir John Hill's attack on Folkes (Review of the Works of the Royal Soc., 1751), see D'Israeli, Calamities and Quarrels of Authors (1800), pp. 364-366. FOLKSTONE, a municipal borough, seaport and watering-place of Kent, England, within the parliamentary borough of Hythe, 71 m. S.E. by E. of London by the South-Eastern & Chatham railway. 29°09' 55°01' (100). pop. 18,000; 32,005 (1851). It is one of the principal ports in cross-Channel communications, the steamers serving Boulogne, 30 m. distant. The older part of Folkstone lies in a small valley which here opens upon the shore between steep hills. The more modern portions extend up the hills on either hand. To the north the town is sheltered by hills rising sharply to heights of 400 to 500 ft., on several of which, such as Sugarloaf and Castle Hills, are ancient earthworks. Above the cliff west of the old town is a broad promenade called the Lees, commanding a notable view of the channel and connected by lifts with the shore below. On this cliff also stands the parish church of St Mary and St Eanswith, a cruciform building of much interest, with central tower. It is mainly Early English, but the original church, attached to a Benedictine priory, was founded in 1095 on the site of a convent established by Eanswith, daughter of Eadbald, king of Kent in 630. The site of this foundation, however, became endangered by encroachments of the sea. The monastery was destroyed at the dissolution of religious houses by Henry VIII. Folkstone inner harbour is dry at low water, but there is a deep water pier for use at low tide by the Channel steamers, by which not only the passenger traffic, but also a large general trade are carried on. The fisheries are important. Among their products is the mentioned grammar school, founded in 1674, the public library and museum, and a number of hospitals and sanatoria. The discontinued Hervey Institution for young men was named after William Harvey, discoverer of the circulation of the blood, a native of Folkestone (1558), who is also commemorated by a tercentenary memorial on the Lees. Folkstone is a member of the Cinque Port of Dover. It is governed by a mayor, 7 aldermen and 21 councillors. Area, 2,522 acres. To the west of Folkestone, close to the rolling fields, is the populous suburb of Cheriton (an urban district, pop. 7,001).

Folkstone (Folke-stan) was among the possessions of Earl Godwine and was called upon to supply him with ships when he was exiled from England; at the time of the Domesday Survey it belonged to Odo, bishop of Bayeux. From early times it was a member of the Cinque Port of Dover, and had to find one out of the twenty-one ships furnished by that port for the royal service. It shared the privileges of the Cinque Ports, whose liberties were exemplified at the request of the barons of Folkestone by Edward III, in 1350. The corporation, which was representative, was entitled to hold a weekly market and to use the name of Folkestone. The history of Folkestone is a record of its struggle against the sea, which was constantly encroaching upon the town. In 1620 the inhabitants, impoverished by their losses, obtained licence to erect a port. By the end of the 18th century the town had become prosperous by the increase of its fishing and shipping trades, and by the middle of the 19th century one of the chief health and pleasure resorts of the south coast.

FOLKLAND (fökländ). This term occurs three times in Anglo-Saxon documents. In a law of Edward the Elder (c. 112) it is contrasted with bookland in a way which shows that these two kinds of tenure formed the two main subdivisions of landownership: no one is to deny right to another in respect of folkland or bookland. By a charter of 863 (Cod. Dipl. 281), King Æthelberht exchanges five hides of folkland for five hides of bookland which had formerly belonged to a thane, granting the latter for the newly-acquired estates exemption from all fiscal exactions except the threefold public obligation of attending the fyrd and joining in the repair of fortresses and bridges. Evidently folkland was not free from the payment of gafol (land tax) and providing quarters for the king's men. In ealdorman Alfred's will the testator disposes freely of his bookland estates in favour of his sons and his daughter, but to a son who is not considered as rightful offspring five hides of folkland are left, provided the king consents. It is probable that folkland is meant in two or three cases when Latin documents speak of terra rei publicae jure possessa.

Two principal explanations have been given to this term. Allen thought that folkland was similar to the Roman aker publicus: it was the common property of the nation (jus), in the possession of which resided the economic rights of the community, and the tenure for his followers more or less after the fashion of continental beneficia. These estates remained subject to the superior ownership of the folk and of the king: they could eventually be taken back by the latter and, in any case, the heir of a holder of folkland had to be confirmed in possession by the king. A letter of Bede to the archbishop Egbert of York may be interpreted to apply to this kind of tenure. Kemble, K. Maurer, H. C. Lodge, Stubbs and others followed Allen's lead.

Another theory was started by Professor Vinogradoff in an article on folkland in the English Hist. Review for 1894. It considers folkland as landownership by folkright—common law, as might be said in modern legal speech. In opposition to it bookland appears as landownership derived from royal privilege. The incidents recorded in the charters characterize folkland as
subject to ordinary fiscal burdens and to limitations in respect of testamentary succession. Thane Walla has to be relieved from fiscal exactions when his estate is converted from folkland into bookland (C.D. 281). Ealdorman Alfred’s son, not being recognized as legitimate, has to claim folkland not by direct succession or devise, but by the consent of the king. These incidents and limitations are thrown into relief by copious illustrations as to the fundamental features of bookland contained in the numberless tales themselves, as are the exemptions from fiscal dues and freedom of disposition of the owner. The study of the matter has been accepted by the chief modern authorities.

FOLKLORE, a term invented in 1846 by Mr W. J. Thoms as a designation for the traditional learning of the uncultured classes of civilized nations. The word has been adopted in this sense into many foreign languages; it is sometimes regarded as the equivalent of the Ger. Volkskunde. But folklore is, properly speaking, the “lore of the folk,” while Volkskunde is lore or learning about the folk, and includes not only the mental life of a people, but also their arts and crafts. The term folklore is also used to designate the science which deals with folklore; the study of survivals involves the investigation of the similar customs, beliefs, &c., of races on lower planes of culture; consequently folklore, as interpreted by the English and American societies, concerns itself as much or more with savage races as with the popular superstitions of the white races.

History.—The scientific study of folklore dates back to the first quarter of the 19th century, but folklore was collected long before that date. The organized study of folklore is a thing of recent growth. The first Folklore Society was founded in London in 1878; similar bodies now exist in the United States, France, Italy, Switzerland, and especially in Germany and Austria. The folk-tale makes its appearance in literature at a very early period; Egyptian examples have come down to us from the 28th century B.C. In Greece the Homeric poems contain many folk-tale incidents; for India we have the Jatakas and Panchatantra; and for the Arabs the great collection of the Thousand and One Nights. Another type of folk-narrative is represented by Aesop’s Fables. Not unnaturally beliefs and customs received less attention; our knowledge of them among the ancients is as a rule pieced together. Among the oldest professed collections are J. B. Thiers (1606–1703), Traité des superstitions (1679), Aubreÿ’s Miscellaneis (1680) and H. Bourne’s (1656–1730) Antiquitates vulgares (1725); but they belong to the antiquarian, non-scientific period. The pioneers of the modern scientific treatment of folklore were the brothers Grimm, by the publication of their Kinder-und Hausmärchen (1812–1815) and Deutsche Mythologie (1835). They were the first to present the folk-tale in its genuine unadulterated form. They differed from their predecessors in regarding the myth, not as the result of conscious speculation, but of a mythopoetic impulse. They were, however, the first to press modern linguistic evidence to hand and to make the figures of the folk-tale the line representatives of ancient gods, as the folk-tales themselves were of the myths. This tendency was exaggerated by their successors, J. W. Wolf, W. Röchholz and others. At the outset of his career, W. Mannhardt (1831–1886), the forerunner of the anthropological school of folklore, shared in this mistake. Breaking away eventually from the philological schools, which interpreted myths and their supposed descendants, the folk-tales, as relating to the storm, the sun, the earth, &c. (see MYTHOLOGY), Mannhardt made for himself to collect and compare the survivals of the peasantray; but his health was always feeble and he never completed his scheme. For a time Mannhardt’s researches bore fruit neither in his own country nor abroad. In 1878 the foundation of the Folklore Society marked a new era in England, where the philological school had had few adherents; and the anthropological school soon produced evidence of its vitality in the works of Mr Andrew Lang, Dr J. G. Frazer and Professor Robertson Smith.

With the growth of our knowledge of European folk-custom and belief on the one hand, and of rites and religions of people in the lower stages of culture on the other hand, it has become abundantly clear that there is no line of demarcation between the two. Each throws light upon the other, and the superstitions of Europe are the lineal descendants of savage creeds which have their parallels all over the world in the culture of primitive peoples.

Subdivisions.—The folklore of civilized peoples may be conveniently classified under three main heads: (1) belief and custom; (2) narratives and sayings; (3) art. These again may be subdivided. The first division, Belief and Custom, includes (A) Superstitious beliefs and practices, including (a) those connected with natural phenomena or inanimate nature, (b) tree and plant superstitions, (c) animal superstitions, (d) ghosts and goblins, (e) witchcraft, (f) leechcraft, (g) magic in general and divination, (h) eschatology, and (i) miscellaneous superstitions and practices; and (b) Traditional customs, including (a) festival customs for which are set aside certain days and seasons, (b) ceremonial customs on the occasion of events such as birth, death or marriage, (c) games, (d) miscellaneous local customs, such as agricultural rites connected with the corn-spirit (see DEMONOLOGY), and (e) dances. The second head of Narratives and Sayings may be subdivided (A) into (a) sagas or tales told as true, (b) Marchen or nursery tales, (c) fables, (d) diries, (e) apodes, cumulative tales, &c., (e) myths (see MYTHOLOGY), and (f) place legends; (B) into ballads and songs (in so far as they do not come under art); and (C) into nursery rhymes, riddles, fings, proverbs, nicknames, place rhymes, &c. The third head, Art, subdivides into (a) folk music with ballads and songs, (b) folk drama. Any classification, however, labours under the disadvantage of separating items which properly belong together. Thus, myths are obviously the form in which some superstitions are expressed. They may also be aetiological in their nature and form an elaborate record of a custom. Eschatological beliefs naturally take the form of myths. Traditional narratives can also be classified under art, and so on.

Literature.—The literature of the subject falls into two sharply defined classes—synthetic works and collections of folklore—of which the latter are immensely more numerous. Of the former class the most important is Dr J. G. Frazer’s Golden Bough, which sets out from the study of a survival in Roman religion and extends to a wide field of savage and civilized beliefs and customs. Especially important are the chapters on agricultural festivals, in which are set forth the results of Mannhardt’s researches. Other important lines of folklore research in the Golden Bough are those dealing with spring ceremonies, with the primitive view of the soul, with animal cults, and with sun and rain charms. Mr E. S. Hartland’s Legend of Perseus is primarily concerned with the origin of a folk-tale, and this problem in the end is dismissed as insoluble. A large part of the book is taken up with a discussion of sympathetic magic, and especially with the “life index,” an object set upon with more or less realistic being that it acts as an indication of his well-being or otherwise. The importance of children’s games in the study of folklore has been recognized of recent years. An admirable collection of the games of England has been published by Mrs G. L. Gomme. The more recent study of uncivilized peoples the problem of the diffusion of games has also come to the fore. In particular it is found that the string-game called "cat’s cradle in various forms is of very wide diffusion, being found even in Australia. The knowledge of folk-music has recently received much attention (see Song).

BIBLIOGRAPHY.—Introductory works: M. R. Cox, Introduction to Folklore; Rainhil, Die Volkkskunde; Marinil in Revue de I’histoire des religions, vili. 166, and other works mentioned by Rainhil. Other works: G. K. Knight, The Legend of Perseus; A. Lang, Custom and Myth, Myth, Ritual and Religion; J. L. Prineline Culture; Liebrecht, Zur Volkskunde.
of civil law at Giessen. Owing to being suspected of political intrigues, he removed to Jena, and thence, after the assassination of Kotzebue, fled to France. Here again the political murder of the duke de Berry, on the 14th of January 1820, led to Follen being regarded as a suspect, and he accordingly took refuge in Switzerland, where he taught for a while at the cantonal school at Coire and at the university of Basel; but the Prussian authorities imperatively demanding his surrender, he sought in vain to find asylum in a neutral State, and finally in America. Here he became an instructor in German at Harvard in 1825, and in 1830 obtained an appointment as professor of German language and literature there; but his anti-slavery agitation having given umbrage to the authorities, he forfeited his post in 1835, and was ordained Unitarian minister of a chapel at Lexington in Massachusetts in 1836. He perished at sea on board a steamboat which was totally consumed by fire while on a voyage from New York to Boston, on the night of the 13th-14th of January 1840. Follen was the author of several celebrated patriotic songs in English.

FOLLET, SIR WILLIAM WEBB (1798-1845), English lawyer, was born at Topsham in Devonshire on the 2nd of December 1798. He was the son of Captain Benjamin Follen, who had retired from the army in 1790, and engaged in business at Topsham. He received his education at Exeter grammar school and Trinity College, Cambridge, graduating in 1818. He had entered the Inner Temple in 1816 and began to practise as a pleader below the bar in 1821, but was called to the bar in 1824, and joined the western circuit in 1825. At the very outset his great qualifications were universally recognized. He was thoroughly master of his profession, and his rapid rise in it was due not only to his quick perception and sound judgment, but to his singular courtesy, kindness and sweetness of temper. In 1830 he married the eldest daughter of Sir Ambrose Harding Gifford, chief justice of Ceylon. In 1835 he was returned to parliament for Exeter. In parliament he early distinguished himself, and under the first administration of Sir Robert Peel was appointed solicitor-general (November 1834); but resigned with the ministry in April 1835. In the course of this year he was knighted. On the return of Peel to power in 1841 Sir William was again appointed solicitor-general, and in April 1844 he succeeded Sir Frederick Pollock as attorney-general. But his health, which had begun to fail him in 1838, and had been permanently injured by the newspaper work and very soon to fail him, was compelled to relinquish practice and to visit the south of Europe. He returned to England in March 1845; but the disease, consumption, reasserted itself, and he died in London on the 28th of June following. A statue of Follen, executed by Behnes, was erected by subscription in Westminster Abbey.

FONBLANQUE, ALBANY WILLIAM (1793-1872), English journalist, descended from a noble French Huguenot family, the Greniers of Languedoc, was born in London in 1793. John Grenier, a banker, became naturalized in England under the name of Fonblanque and had a son named Martin Fonblanque (1760-1838), a distinguished equity lawyer, and the author of a standard legal work, a Treasise on Equity, was the father of Albany Fonblanque; he represented the borough of Camelford in parliament; and was one of the Whig friends of George IV. when prince of Wales. At fourteen young Fonblanque was sent to Woolwich to prepare for the Royal Engineers. His health, however, failed, and for two years his studies had to be suspended. Upon his recovery he studied for some time with a printer to be called to the bar. At the age of nineteen (1812) he commenced writing for the newspapers, and very soon attracted notice both by the boldness and liberality of his opinions, and by

FOLLEN, AUGUST (or, as he afterwards called himself, Adolph Ludwig) (1794-1852), German poet, was born at Giessen on the 21st of January 1794, the son of a district judge. He studied theology at Giessen and law at Heidelberg, and after leaving the university edited the Elberfeld Allgemeine Zeitung. Suspected of being connected with some radical plots, he was imprisoned for two years in Berlin. When released in 1821 he went to Switzerland, where he taught in the canton school at Aarau, from 1826 to 1829, and was ordained a clergyman of the Evangelical Church in 1829, and was afterwards ordained a deacon in the diocese of Thuringia, and then retired to Bern, where he lived till his death on the 26th of December 1855. Besides a number of minor poems he wrote Harfengrüssse aus Deutschland und der Schweiz (1824) and Maleys und Vienan (1829), a knightly romance after the fashion of the romantic school. Of his many translations, mention may be made of the Homeric Hymns in collaboration with R. Schwenck (1814), Tasso's Jerusalem Delivered (1818) and Siegfried Tod from the Nibelungenlied (1842); he also collected and translated Latin hymns and sacred poetry (1810). In 1846 he published a brief collection of sonnets entitled An die geliebten Nichtsträucher. This was aimed at the liberal philosopher Arnold Ruge, and was the occasion of a literary duel between the two authors. Follen's posthumous poem Tristanis Etern (1857) may also be mentioned, but his best-known work is a collection of German poetry entitled Bildersaal deutscher Dichter (1827).
the superiority of his style to what Macaulay, when speaking of him, justly called the "rant and twaddle of the daily and weekly press" of the time. While he was eagerly taking his share in all the political struggles of this eventful period, he was also continuing his studies, devoting no less than six hours a day to the study of classics and political philosophy. Under this severe mental training his health once more broke down. His energy, however, was not impaired. He became a regular contributor to the newspapers and periodicals. Fonblanque, [London, 1847] still somewhat unemployed and with a radical habit, tried to sustain his family by his pen. By 1826 his work was sufficiently paid for him to rent a cottage near the family home, and he was able to devote more time to his writing. He continued to work with a radical bent.

From 1830 to 1830 Albany Fonblanque was successively employed upon the staff of The Times and the Morning Chronicle, whilst he contributed to the Examiner, to the London Magazine and to the Westminster Review. In 1858 the Examiner newspaper, which had been purchased by the Rev. Dr Fellowes, author of the Religion of the Universe, &c., was given over to Fonblanque's complete control; and for a period of seventeen years (1830 to 1847) he not only sustained the high character for political independence and literary ability which the Examiner had gained under the direction of Leigh Hunt and his brother, John Hunt, but even compelled his political opponents to acknowledge a certain delight in the boldness and brightness of the wit directed against themselves. When it was proposed that the admirers and supporters of the paper should facilitate a reduction in its price by the payment of their subscription ten years in advance, not only did Mr Edward Bulwer (Lord Lytton) volunteer his aid, but also Mr Disraeli, who was then about to enter into Parliament. During his connexion with the Examiner, Fonblanque had many advantageous offers of further literary employment; but he devoted his energies and talents almost exclusively to the service of the paper he had resolved to make a standard of literary excellence in the world of journalism. Fonblanque was offered the governorship of Nova Scotia; but although he took great interest in colonial matters, and had used every effort to advocate the more generous political system which had colonial self-government for its goal, he decided not to abandon his beloved Examiner even for so sympathetic an employment. In 1847, however, domestic reasons induced him to accept the post of statistical secretary of the Board of Trade. This of course compelled him to resign the editorship of the Examiner, but he still continued to contribute largely to the paper, which, under the control of John Forster, continued to sustain its influential position. During the later years of his life Fonblanque took no prominent part in public affairs; and when he died at the age of seventy-nine (1872) he seemed, as his nephew, Edward Fonblanque, rightly observes, "a man who had lived and fought in an age gone by and in a cause long since established as a failure." The character of Albany Fonblanque's political activity may be judged of by a study of his England under Seven Administrations (1837), in comparison with the course of social and political events in England from 1826 to 1837. As a journalist, he must be regarded in the light of a reformer. Journalism before his day was regarded as a somewhat discreditable profession; men of true culture were shy of entering the hot and dusty arena lest they should be confounded with the ruder combatants who fought there before the public for hire. The very fact that Fonblanque, a man of strong and earnest political convictions but also of exceptional literary ability, did not hesitate to choose this field as a worthy one in which both a politician and a man of letters might usefully as well as honourably put forth his best gifts, must have helped, in no small degree, to correct the old prejudice.

See the Life and Labours of Albany Fonblanque, edited by his nephew, Edward Baring Fonblanque, 1874; a copy of this article with a brief biographical notice.

FOND DU LAC—FONDI

FOND DU LAC, a city and the county-seat of Fond du Lac county, Wisconsin, U.S.A., about 60 m. N. of Milwaukee, at the S. end of Lake Winnebago, and at the mouth of the Fond du Lac river, which is navigable for only a short distance. Pop. (1890) 12,024; (1900) 15,110, of whom 2052 were foreign-born; (1910) 18,797. The city is a railway centre of some importance, and is served by the Chicago, Milwaukee & St Paul, the Minneapolis, St Paul & Sault St Marie, and the Chicago & North-Western railways, by interurban electric lines, and by steamboat lines connecting through the Fox river with vessels on the Great Lakes. At North Fond du Lac, just beyond the city limits, are car-shops of the two last-mentioned railways, and in the city are manufactories of machinery, automobiles, wagons and carriages, sawmills, leather, beer, flour, refrigerators, agricultural implements, toys and furniture. The total value of the city's factory products in 1905 was $5,599,606, an increase of 95.7% since 1900. The city has a Protestant Episcopal cathedral, the Grafton Hall school for girls, and St Agnes hospital and convent, and a public library with about 25,000 volumes in 1908. The first settlers on the site of Fond du Lac arrived about 1833. Subsequently a village was laid out which was incorporated in 1847; a city charter was secured in 1852.

FONDI (anc. Fundi), a town of Campania, Italy, in the province of Caserta, 12 m. N.W. of Formia, and 11 m. E.N.E. of Terracina by road. Pop. (1901) 9030. It lies 5 ft. above sea-level, at the N. end of a plain surrounded by mountains, which extend to the sea. It occupies the site of the ancient Fundi, a Volscian town, belonging later to Latium, on the Via Appia, still represented by the modern high-road which passes through the centre of the town. It is rectangular in plan, and portions of its walls, partly in fine polygonal work and partly in opus incertum, are preserved. Both plan and walls date, no doubt, from the Roman period. The gate on the north-east still remains, with parts of the old column of the priestess of Janus on the gate, the towers, and the wall. A similar inscription on three different pedestals from the N.W. gate still exists, but not in situ. In the neighbourhood are the remains of several ancient villas, and along the Via Appia still stands an ancient wall of opus reticulatum, with an inscription, in large letters, of one Varronanus, the letters being at intervals of 25 ft. The engineering of the ancient Via Appia between Fondi and Formia, where it passes through the mountains near Iti, is remarkable.

The modern town is still enclosed by the ancient walls. The castle on the S.E. side has some 15th-century windows with beautiful tracery. Close by is the Gothic church of S. Pietro (formerly S. Maria), which was the cathedral until the see was suppressed in 1818 and united with that of Gaeta; it contains a fine pulpit with "cosmatasque" work and the fine tomb of Cristoforo Caetani (1439), two interesting 15th-century triptychs and an episcopal throne, which served for the coronation of the antipope Clement VII. in 1538. In the Dominican monastery the cell which St Thomas Aquinas sometimes occupied as an ancient fundi of Formia is preserved (with Formiae) the civitas sine suffragio, because it had always secured the Romans safe passage through its territory; the people as a whole did not join Drivenum in its war against Rome three years later, though Vitruvius Vacca, the leader, was a native of Fundi. It acquired the full citizenship in 158 B.C., and was partly under the control of a praefectus. The inscription upon some waterpipes which have been discovered shows that later it became a municipium. It was governed by three scelae Horace's jest against the officius praetor (sic.) is due to the exigencies of metre (Th. Mommsen in Hermes, xiii. p. 115). The family of Livia, the consort of Augustus, belonged to Fundi. During the Lombard invasions in 592 Fundi was temporarily abandoned, but it seems to have come under the rule of the patricy by a.d. 754 at any rate. Pope John VIII. ceded it with its territory to Decisile, duke of Gaeta, but its history is somewhat intricate after this period. Sometimes it appears as an independent countship, though held by men of the family of Poggiolli about 1200; sometimes by the Chianchi family (London, 1874); sometimes by the Chianchi family and the D'Ambra family; and at last in 1504 it was given to Prospero Colonna. In 1534 Klaire-red-Barbara Rossa tried to carry off Giulia Gonzaga, countess of Fondi, and sacked the city. After this Fondi was much neglected; in 1721 it was sold to the Di Sangro family, in which it still remains. Its position as a frontier town between the papal states and the kingdom of Naples, just in the territory of the latter—the Via Appia can easily be blocked either N.W. at the actual frontier called
Portella or S.E. of it—a good deal during the French Revolution and the events which led up to the unification of Italy.

The Lago di Fondi, which lies in the middle of the plain, and the partially drained marshes surrounding it, compelled the ancient Via Appia, followed by the modern road, to make a considerable détour. The lake was also known in classical times as lacus Amyclanus, from the town of Amyclae or Amunciae, which was founded, according to legend, by Spartan colonists, and probably destroyed by the Oscans in the 5th century B.C. (E. Pais in Rendiconti dei Lincei, 1906, 611 seq); the bay was also known as mare Amunculorum.

The ancient Speluncae (mod. Sperlonga) on the coast also belonged to the territory of Fundi. Here was the imperial villa in which Sejanus saved the life of Tiberius, who was almost crushed by a fall of rock. Considerable remains of it, and of the caves from which it took its name, still exist 1 m. S.E. of the modern village. For modern discoveries see P. di Tucci in Notizia degli scavi (1886), 480; G. Patroni, ibid. (1868), 493.

The wine of Fundi is spoken of by ancient writers, though the ager Caccubus, the coast plain round the Lago di Fundi, was even more renowned, and Horace frequently praises its wine; and though Pliny the Elder speaks as if its production had almost entirely ceased in his day (attributing this to neglect, but even more to the excavation works of Nero's projected canal from the Lacus Avernus to Ostia), Martial mentions it often, and it is spoken of in the inscription of a wine-dealer of the time of Hadrian, together with Falernian and Paestum wines (corpus inscr. Lat. vi. Berlin, 1882, 9707).

The plain of Fondi is the northernmost point in Italy where the cultivation of oranges and lemons is regularly carried on in modern times.

See G. Conte Colino, Storia di Fondi (Naples, 1902); B. Amante and R. Bianchi, Memorie storiche e statutarie di Fondi in Campania (Rome, 1903); T. Ashby, in English Historical Review, 23rd of June 1904, 593; (T. As.)

FONNI, a town of Sardinia, in the province of Sassari, 3280 ft. above sea-level, to the N.W. of Monte Gennargentu, 21 m. S. of Nuoro by road. Pop. (1901) 4323. It is the highest village in Sardinia, and situated among fine scenery with some chestnut woods. The church of the Franciscans, built in 1708, contains some curious paintings by local artists. The costumes are extremely picturesque, and are well seen on the day of St John the Baptist, the patron saint. The men's costume is similar to that worn in the district generally; the linen trousers are long and black gaiters are worn. The women wear a white chemise; over that a very small corset, and over that a red jacket with blue and black velvet facings. The skirt is brown above and red below, with a blue band between the two colours; it is accordian-pleated. Two identical skirts are often worn, one above the other. The unmarried girls wear white kerchiefs, the married women black. A little to the N. of Fonni, by the high-road, stood the Roman station of Soralibe, mentioned in the Antonine Itinerary as situated 87 m. from Carales on the road to Olbia. Excavations made in 1879 and 1880 led to the discovery of the remains of this station, arranged round three sides of a courtyard some 100 ft. square, including traces of baths and other buildings, and a massive embankment wall above them, some 150 ft. in length, to protect them from landslips (F. Vivinet, in Notizie degli scavi, 1879, 350; 1881, 31), while a discharge certificate (tabula homenae missionis) of sailors who had served in the classis Ravennas was found in some ruins here or herabouts (id. ib., 1882, 440; T. Mommsen, Corp. inscr. Lat. x. 8325). Near Fonni, too, are several menhirs (called pietre celliche in the district) and other prehistoric remains.

FONSAGRADA, a town of north-western Spain, in the province of Lugo; 25 m. E.N.E. of Lugo by road. Pop. (1900) 17,302. Fonsagrada is situated 3160 ft. above the sea, on the watershed between the rivers Rodil and Suarri. It is an important market for all kinds of agricultural produce, and manufactures linen and frieze; but its trade is mainly local, owing to the mountainous character of the neighbourhood, and the lack of a railway or navigable waterway, which prevent the development of any considerable export trade.

FONSECA, MANUEL DEODORO DA (1827-1892), first president of the united states of Brazil, was born at Alagoas on the 5th of August 1827, being the third son of Lieut.-Colonel Manuel Fonseca da Fonseca (d. 1889). He was educated at the military school of Rio de Janeiro, and attained the rank of captain in the Brazilian army when war broke out in 1854 against Montevideo, and afterwards against Solano Lopez, dictator of Paraguay. His courage gained him distinction, and before the close of the war in 1870 he reached the rank of colonel, and some years later that of general of division. After holding several military commands, he was appointed in 1886 governor of the province of Rio Grande do Sul. In this position he threw himself heartily into politics, espoused the republican opinions then becoming prevalent, and sheltered their exponents with his authority. After a fruitless remonstrance, the government at the close of the year removed him from his post, and recalled him to the capital as director of the service of army material. Finding that even in that post he still continued to encourage insubordination, the minister of war, Alfredo Chaves, dismissed him from office. On 14th of May 1887, in conjunction with the viscount de Pelotas, Fonseca issued a manifesto in defence of the military officers' political rights. From that time his influence was supreme in the army. In December 1888, when the Conservative Correia d'Oliveira became prime minister, Fonseca was appointed to command an army corps on the frontier of Matto Grosso. In June 1889 the ministry was overthrown, and on a dissolution an overwhelming Liberal majority was returned to the chamber of deputies. Fonseca returned to the capital in September. Divisions of opinion soon arose within the Liberal party on the question of provincial autonomy. The more extreme desired the inauguration of a complete federal system. Amongst the most vehement was Ruy Barbosa, the journalist and orator, and after some difficulty he persuaded Fonseca to head an armed movement against the government. The insurrection broke out on the 15th of November 1889. The government commander, Almeida Barreto, hastened to place himself under Fonseca's orders, and the soldiers and sailors made common cause with the insurgents. The affair was much bloodless, the minister of marine, baron de Ladario, being the only person wounded. Fonseca had only intended to overturn the ministry, but he yielded to the insolvency of the republican leaders and proclaimed a republic. A provisional government was constituted by the army and navy in the name of the nation, and Fonseca became its chief. The council was abolished, and both the senate and the chamber of deputies were dissolved. The emperor was requested to leave the territory of Brazil within twenty-four hours, and on the 17th of November was embarked on a cruiser for Lisbon. On the 20th of December a decree of banishment was pronounced against the imperial family. So universal was the republican sentiment that there was no attempt at armed resistance. The provisional government exercised dictatorial powers for a year, and on the 25th of February 1893 Fonseca was elected president of the republic. He was, however, a confirmed republican, and possessed indeed little ability beyond the art of acquiring popularity. His tenure of office was short. In May 1894 he became involved in an altercation with congress, and in November pronounced its dissolution, a measure beyond his constitutional power. After a few days of arbitrary rule insurrection broke out in Rio Grande do Sul, and before the close of November Fonseca, finding himself forsaken, resigned his office. From that time he lived in retirement. He died at Rio de Janeiro on the 23rd of August 1892.

FONTE, AMARAL, or CONCHAGUA, BAY OF, an inlet of the Pacific Ocean in the volcanic region between the Central American republics of Honduras, Salvador and Nicaragua. The bay is unsurpassed in extent and security by any other harbour on the Pacific. It is upwards of 30 m. in greatest length, by about 30 m. in average width, with an entrance from the sea about 18 m. wide, between the great volcanoes of Conchagua (3800 ft.)
and Cozeguina (3000 ft.). The lofty islands of Conchagua and Mianguiri, with a collection of rocks called "Los Farellones," divide the entrance into four distinct channels, each of sufficient depth for the largest vessels. A channel called "El Estero Real" extends from the extreme southern point of the bay into Nicaragua for about 50 m., reaching within 20 or 25 m. of Lake Managua. The principal islands in the bay are Sacate Grande, Tigre, and Isla del Tigre, belonging to Honduras, and Martin Perez, Punta Sacate, Conchagua, and Marsa, belonging to Salvador. Of these Sacate Grande is the largest, being about 7 m. long by 4 broad. The island of Tigre from its position is the most important in the bay, being about 20 m. in circumference, and rising in a cone to the height of 2500 ft.

On the southern and eastern shores of the island the lava forms black rocky barriers to the waves, varying in height from 10 to 80 ft.; but on the northward and eastward are a number of playas or smooth, sandy beaches. Facing one of the most considerable of these is the port of Amapala (q.v.). Fonseca Bay was discovered in 1522 by Gil Gonzalez de Avila, and named by him after his patron, Archbishop Juan Fonseca, the implacable enemy of Columbus.

**FONT** (Lat. *fons*, "fountain" or "spring," Ital. *fonte*, Fr. *les fonts*), the vessel used in churches to hold the water for Christian baptism. In the apostolic period baptism was administered at rivers or natural springs (cf. Acts viii. 36), and no doubt the primitive form of the rite was by immersion in the water. *Injunction*—pouring water on the head of the neophyte—was early introduced into the west and north of Europe on account of the inconvenience of immersion, as well as its occasional danger; this form has never been countenanced in the Oriental churches. *Aspersion*, or sprinkling, was also admitted as valid, but recorded early examples of its use are rare (see *Baptism*). These different modes of administering baptism have caused corresponding changes in the receptacles for the water. After the cessation of persecution, when ritual and ornament began to develop openly, special buildings were erected for administering the rite of baptism. This was obviously necessary, for a large *piscina* (basin or tank) in which candidates could be immersed would occupy too much space of the church floor itself. These baptisteries consisted of tanks entered by steps (an ascent of three, and descent of four, to the water was the normal but not the invariable number) and covered with a domed chamber (see *Baptistry*).

By the 9th century, however, the use of separate baptisteries had generally given place to that of fonts. The material of which these were made was stone, often decorative marble; as early as 524, however, the council of Lrda enacted that if a stone font were not procurable the priest might provide a suitable vessel for use for the sacrament exclusively, which might be of any material. In the Eastern Church the font never became an important decorative article of church furniture: "The font, κολωνία [s] (says Neale, *Eastern Church*, i. 214), in the Eastern Church is a far less conspicuous object than it is in the West. Baptism by immersion has been retained; but the font seldom or never possesses any beauty. The material is usually either metal or wood. In Russia the *columbē* is movable and only brought out when wanted."

One of the most elaborate of early fonts is that described by Anastasius in the Lateran church at Rome, and said to have been presented thereto by Constantine the Great. It was of porphyry, overlaid with silver inside and out. In the middle were two porphyry pillars carrying a golden dish, on which burnt the Paschal lamp (having an asbestos wick and fed with balsam). On the rim of the bowl was a golden lamb, with silver statues of Christ and St. John the Baptist. Seven silver stages poured out water. This elaborate vessel was of course exorbitant; the majority of early fonts were certainly much simpler. A fine early Byzantine stone example exists, or till recently existed, at Contra-Sheba.

Few if any fonts survive older than the 11th century. These are all of stone, except a few of lead; much less common are fonts of cast bronze (a fine example, dated 1112, exists at the Church of St. Barthélemy, Liège). The most ancient are plain cylindrical bowls, with a circular—sometimes cruciform or quatrefoil—outline to the basin, either without support or with a single central pillar; occasionally there is more than one pillar. The basins are usually lined with lead to prevent absorption by the stone. The church of Efenechyd, Denbigh, possesses an ancient font made of a single block of oak. Though the circular form is the commonest, early Romanesque fonts are not infrequently square; and sometimes an inverted truncated cone is found. Octagonal fonts are also known, though uncommon; hexagons are even less common, and pentagons very rare. There is a pentagonal font of this period at Cabourg, dept. Calvados, N. France.

Fonts early began to be decorated with sculpture and relief. Arcading and interlacing work are common; so are symbol and pictorial representation. A very remarkable leaden font is preserved at Strassburg, bearing reliefs representing scenes in the life of Christ. At Pont-A-Mousson on the Moselle are bas-reliefs of St. John the Baptist preaching, and baptizing Christ. Caryatides sometimes take the place of the pillars, and sculptured animals and grotesques of strange design not infrequently form the base. More remarkable is the occasional persistence of pagan symbolism; an interesting example is the very ancient font from Ottrava, Sweden, which, among a series of Christian symbols and figures on its panels, bears a representation of Thor (see G. Stephens' brochure, *Thor's Thunderer*).

In the 13th century octagonal fonts became common. A very characteristic example is the font set up in 1263 in the cathedral at Hanover, resting on four kneeling figures, each bearing a vase from which water is running (typical of the rivers of Paradise). Above is an inscription explaining the connexion of these rivers with the virtues of temperance, courage, justice and prudence. On the sides of the cup are representations of the passage of the Jordan, of the Red Sea, the Baptism of Christ, and the Virgin and Child. The font has a conical lid, also ornamented with bas-reliefs. A cast of this font is to be seen in the Victoria and Albert Museum at South Kensington. A leaden font, with figures of Our Lord, the Virgin Mary, St. Martin, and the twelve Apostles, exists at Mainz; it is dated 1328 by a set of four leonine hexameters inscribed upon it. In the 14th and succeeding centuries octagonal fonts became the rule. They are delicately ornamented with mouldings and similar decorations, in the contemporary style of Gothic architectural art. Though the basin is usually circular in 13th-century fonts, examples are not infrequently found in which the outline of the basin follows the octagonal shape of the outer surface of the vessel: the fonts of this type are to be found at Strasbourg, Freiburg and Basel.

In England no fonts can certainly be said to date before the Norman conquest, although it is possible that a few very rude examples, such as those of Wawhaway, Cornwall, and Denton, Sussex, are actually of Saxon times; of course we cannot count as "Saxon fonts" those adapted from pre-Norman sculptured stones originally designed for other purposes, such as that at Dolton, Devonshire. On the other hand, Norman fonts are very common, and are often the sole surviving relics of the Norman parish church. They are circular or square, sometimes plain, but generally covered with carving of arcades, figures, foliage, &c. Among good examples that might be instanced of this period are Alphington, Devon (inverted cone, without foot); Stoke Cannon, Devon (supported on caryatides); Ilam, Staffs (cup-shaped); Fincham, Burnham Deepdale, Stalhthorpe, Toftres, and Sherborne in Norfolk (all, especially the last, remarkable for elaborate carving); Youlgreave, Derby (with a projecting stump in the side for the chiselled unique detail); Such fonts are also known at Lichfield, Oxford, Newport, Kent; Coleshill, Warwick; East Meon, Hants; Castle Fore, Herefordshire. Some of the best examples of "Norman fonts" in England (such as the notable specimen in Winchester cathedral) were probably imported from Belgium. In the transitional period we may mention a remarkable octagonal font at Belton, Lincolnshire; in this period fall most of the leaden fonts that remain in England, of which thirty are known (7 in
Gloucestershire, 4 in Berkshire and Kent, 3 in Norfolk, Oxford and Sussex, 1 in Derby, Dorset, Lincoln, Somerset, Surrey and Wiltshire); perhaps the finest examples are at Ashover, Derbyshire, and Walton, Surrey. Early English fonts are comparatively rare. They bear the moulding, foliage and tooth ornament in the usual style of the period. A good example of an Early English font is at All Saints, Leicester; others may be seen at St Giles, Oxford, and at Lacksond, Suffolk. Fonts of the Decorated period are commoner, but not so frequent as those of the preceding Norman or subsequent Perpendicular periods. Fonts of the Perpendicular period are very common, and are generally raised upon steps and a lofty stem, which, together with the body of the font, are frequently richly ornamented with panelling. It was also the custom during this period to ornament the font with shields and coats of arms and other heraldic insignia, as at Here, Kent. The fonts of this period, however, are as a rule devoid of interest, and, like most Perpendicular work, are stiff and monotonous. There is, however, a remarkable font, with sculptured figures, belonging to the late 14th century, at West Drayton in Middlesex.

In Holyrood chapel there was a brazen font in which the royal children of Scotland were baptized. It was carried off in 1544 by Sir R. Lea, and given by him to the church at St Albans, but was afterwards destroyed by the Puritans. A silver font existed at Canterbury, which was sometimes brought to Westminster on the occasion of a royal baptism. At Chobham, Surrey, there is a fine Saxon font covered with oak leaves of the 16th century. The only existing structure at all recalling the ancient baptisteries in English churches is found at Luton in Bedfordshire. The font at Luton belongs to the Decorated style, and is enclosed in an octagonal structure of freestone, consisting of eight pillars about 25 ft. in height, supporting a canopy. The space around the font is large enough to hold twelve adults comfortably. At the top of the canopy is a vessel for containing the consecrated water, which when required was let down into the font by means of a pipe.

In 1326 it was ordered by Edmund, archbishop of Canterbury, that baptismal fonts should be kept under lock and key, as a precaution against sorcery:—"Fonts baptismales sub sera clausi teneantur propter sortilegiu." The lids appear at first to have been quite simple and flat. They gradually, however, partook of the ornamentation of the font itself, and are often of pyramidal and conical forms, highly decorated with finials, crockets, mouldings and grotesques. Sometimes these covers are very heavy and are suspended by chains to enable them to be raised at will. Very rich font covers may be seen at Ewelme, Oxfordshire, and at St Edmundsbury. Another fine font, covered with oak leaves, is found at Warmington, Northamptonshire, and at Worlingworth, Suffolk. The ordinary position of the font in the church was and is near the entrance, usually to the left of the south door.

(R. A. S. M.)

**FONTAINE, PIERRE FRANÇOIS LÉONARD** (1762-1853), French architect, was born at Fontoise on the 20th of September 1762. He came of a family several of whose members had distinguished themselves as architects. Leaving the college of Fontoise at the age of sixteen he was sent to l'Isle-Adam to assist in hydraulic works undertaken by the architect André. To facilitate his improvement André allowed him to have access to all the plans and drawings of his own designs. On 12th October 1779 he was sent to Paris to study in the school of Peyre the younger, and there began his acquaintance with Percier, which ripened into a life-long friendship. After six years of study he competed for a prize at the Academy, and, winning the second for the plan of an underground chapel, he received a pension and was sent to Rome (1785). Percier accompanied him. The Revolution breaking out soon after his return to France, he took refuge in England; but after the establishment of the consulate he was employed by Bonaparte, to whom he had been introduced by the painter, David, to restore the palace of Malmaison. Henceforth he was fully engaged in the principal architectural works executed in Paris as architect successively to Napoleon I., Louis XVIII. and Louis Philippe. In conjunction with Percier (till his death) he was employed on the arch of the Carrousel, the restoration of the Palais-Royal, the grand staircase of the Louvre, and the works projected for the union of the Louvre and the Tuileries. In 1812 he was admitted to the members of the Academy of Fine Arts, and in 1813 was named first architect to the emperor. With Percier he published the following works—*Palais, maisons, et autres édifices de Rome moderne* (1822); *Descriptions de cérémonies et de fêtes* (1807 and 1816); *Recueil de décorations intérieures* (1812); *Choix des plus belles maisons de plaisance de Rome et des environs* (1809-1813); *Restitutions des souverains, Parallèle* (1833). L'histoire du Palais-Royal was published by Fontaine alone, who lost Percier, his friend and associate, in 1838, and himself died in Paris on the 10th of October 1853.

**FONTAINEBLEAU,** a town of northern France, capital of an arrondissement in the department of Seine-et-Marne, 37 m. S.E. of Paris on the railway to Lyons. Pop. (1906) 11,108. Fontainebleau, a town of clean, wide and well-built streets, stands in the midst of the forest of Fontainebleau, nearly 2 m. from the left bank of the Seine. Of ancient houses, the Fontainebleau mansion, and a portion of that which belonged to the cardinals of Ferrara, both of the 16th century, are still preserved; apart from the palace, the public buildings are without interest. A statue of General Damesne (d. 1848) stands in the principal square, and a monument to President Carnot was erected in 1895. Fontainebleau is the seat of a subprefecture and has a tribunal of first instance and a communal college. The school of practical artillery and engineering was transferred to Fontainebleau from Metz by a decree of 1871, and now occupies the part of the palace surrounding the central court.

Fontainebleau has quarries of sand and sandstone, saw-mills, and manufactories of porcelain and gloves. Fine grapes are grown in the vicinity. The town is a fashionable summer resort, and during the season the president of the Republic frequently resides in the palace. This famous building, one of the largest, and in the interior one of the most sumptuous, of the royal residences of France, lies immediately to the south-east of the town. It consists of a series of courts surrounded by buildings, extending from W. to E.N.E.; they comprise the Cour du Cheval Blanc or des Ténèbres (in the middle of the 13th century), the d'Henri IV., and the d'Henri II., at the foot of the double staircase between Napoleon and the Old Palace (1840); the Cour de la Fontaine, the Cour Ovale, built on the site of a more ancient château, and the Cour d'Henri IV.; the smaller Cour des Princes adjoins the northern wing of the Cour Ovale. The exact origin of the palace and of its name (Lat. Fons Bleaudi) is equally unknown, but the older château was used in the latter part of the 12th century by Louis VII., who caused Thomas Becket to consecrate the Chapelle St Saturnin, and it continued a favourite residence of Philip Augustus and Louis IX. The creator of the present edifice was Francis I., under whom the architect Gilles le Breton erected most of the buildings of the Cour Ovale, including the Porte Dorée, its southern entrance, and the Salle des Fêtes, which, in the reign of Henry II., was decorated by the Italians, Francesco Primaticcio and Nicolo dell' Abbate, and is perhaps the finest Renaissance chamber in France. The Galerie de François I. and the lower storey of the left wing of the Cour de la Fontaine are the work of the same architect, who also rebuilt the two-storeyed Chapelle St Saturnin. In the same reign the Cour du Cheval Blanc, including the Chapel of the Sts. Trinité and the Galerie d'Ulysse, destroyed and rebuilt under Louis XV., was constructed by Pierre Chambiges. After Francis I., Fontainebleau owes most to Henry IV., to whom are due the Cour d'Henri IV., the Cour des Princes, with the adjoining Galerie de Diane, and Galerie des Cerfs, used as a library. Louis XIII. built the graceful horseshoe staircase in the Cour du Cheval Blanc; Napoleon I. spent 12,000,000 francs...
on works of restoration, and Louis XVIII., Louis Philippe and Napoleon III. devoted considerable sums to the same end. The palace is surrounded by gardens and ornamental waters—to the north the Jardin de l’Orangerie, to the south the Jardin Anglais and the Parterre, between which extends the lake known as the Bassin des Carpes, containing carp in large numbers. A space of over two hundred acres, with a circumference of 56 m. Near a quarter of this area is of a rocky nature, and the quarries of sandstone supplied a large part of the paving of Paris. The oak, pine, beech, hornbeam and birch are the chief varieties of trees.

It is impossible to do more than mention a few of the historical events which have taken place at Fontainebleau. Philip the Fair, Henry III. and Louis XIII. were all born in the palace, and the first of these kings died there. James V. of Scotland was there received by his intended bride; and Charles V. of Germany was entertained there in 1536, with a processional in the gardens of Fontainebleau. The garden is still to be seen where in 1657 she caused her secretary Monaldeschi to be put to death. In 1685 Fontainebleau saw the signing of the revocation of the edict of Nantes, and in the following year the death of the great Condé. In the 18th century it had two illustrious guests in Peter the Great of Russia and Christian VII. of Denmark; and in the early part of the 19th century it was twice the residence of Pius VII., in 1804 when he came to consecrate the emperor Napoleon, and in 1812-1814, when he was his prisoner.

FONTANA, LOUIS MARIE (1801-1839), French man of letters, was born at Lorient on the 4th of November 1801. He began his career as a clerk in a government office, but was dismissed for taking part in a political banquet. At the age of nineteen he went to Paris and began to contribute to the Tablelles and the Album. He was brought to trial for political articles written for the latter paper, but defended himself so energetically that he secured the indefinite postponement of his case. The offending paper was suppressed for a time, and Fontan produced a collection of political poems, Odes et épitres, and a number of plays, of which Perkins Warbeck (1838), written in collaboration with MM. Halévy and Drouineau, was the most successful. In 1828 the Album was revived, and in the Fontan published a virulent but witty attack on Charles X., entitled Le Mouton enragé (26th June 1829). To escape the inevitable prosecution Fontan fled over the frontier, but, finding no safe asylum, he returned to Paris to give himself up to the authorities, and was sentenced to five years’ imprisonment and a heavy fine. He was liberated by the revolution of 1830, and his Jeanne la folle, performed in the same year, gained a success due perhaps more to sympathy with the author’s political principles than to the merits of the piece itself, a somewhat crude and violent picture of Bourbon history. He wrote in collaboration with Charles Duponty, Le Proce d’un maréchal de France (printed 1831), was suppressed on the night of its production. Fontan died in Paris on the 10th of October 1839.

A sympathetic portrait of Fontan as a prisoner, and an analysis of his principal works, to be found in Jules Janin’s Histoire de la littérature dramatique, vol. 1.

FONTANA, DOMENICO (1543-1607), Italian architect and mechanician, was born at Mill, a village on the Lake of Como, in 1543. After a good training in mathematics, he went in 1563 to join his elder brother, then studying architecture at Rome.

He made rapid progress, and was taken into the service of Cardinal Montalto, for whom he erected a chapel in the church of Santa Maria Maggiore and the villa Negroni. When the cardinal’s pension was stopped by the pope, Gregory XIII., Fontana volunteered to complete the works in hand at his own expense. The cardinal being soon after elected pope, under the name of Sixtus V., he immediately appointed Fontana his chief architect. Amongst the works executed by him were the Lateran palace, the palace of Monte Cavallo (the Quirinal), the Vatican library, &c. But the undertaking which brought Fontana the highest repute was the removal of the great Egyptian obelisk, which had been brought to Rome in the reign of Caligula, from the place where it lay in the circus of the Vatican. Its erection in front of St Peter’s he accomplished in 1586. After the death of Sixtus V., charges were brought against Fontana of misappropriation of public moneys, and Clement VIII. dismissed him from his post (1597). This appears to have been just in time to save the Colosseum from being converted by Fontana into a huge cloth factory, according to a project of Sixtus V. Fontana was then called to Naples, and accepted the appointment of architect to the viceroy, the count of Miranda. At Naples he built the royal palace, constructed several canals and projected a new harbour and bridge, which he did not live to execute. The only literary work left by him is his account of the removal of the obelisk (Rome, 1596). He died at Naples in 1607, and was buried with a painted funeral portrait in the church of Santa Chiara. His plan for a new harbour at Naples was carried out only after his death. His son Giulio Cesare succeeded him as royal architect in Naples. His portrait of the university of that town being his best-known building.

FONTANA, LAVINIA (1532-1614), Italian portrait-painter, was the daughter of Prospero Fontana (q.v.). She was greatly employed by the ladies of Bologna, and, going thence to Rome, painted the likenesses of many illustrious personages, being under the particular patronage of the family (Buoncampagni) of Poppo and Gregory XIII., who died in 1585. The Roman ladies, from the days of this pontiff to those of Paul V., elected in 1605, showed no less favour to Lavinia than their Bolognese sisters had done; and Paul V. was himself among her sitters. Some of her portraits, often lavishly paid for, have been attributed to Guido. In works of a different kind also she united care and delicacy with boldness. Among the chief of these are a Venus in the Berlin museum; the Virgin lifting a veil from the sleeping infant Christ, "in the same costume and the same setting as her own portrait in youth—she was accounted very beautiful—was perhaps her masterpiece; it belongs to the counts Zappi of Imola, the family into which Lavinia married. Her husband, whose name is given as Paolo Zappi or Paolo Foppa, painted the draperies in many of Lavinia’s pictures. She is depicted on the whole a better painter than her father; from him naturally came her first instruction, but she gradually adopted the Caracese style, with strong quasi-Venetian coloring. She was elected into the Academy of Rome, and died in that city in 1614.

FONTANA, PROSPERO (1512-1597), Italian painter, was born in Bologna, and became a pupil of Innocenzo da Imola. He afterwards worked for Vasari and Perino del Vaga. It was probably from Vasari that Fontana acquired a practice of off-hand, self-displaying work. He undertook a multitude of commissions, and was so rapid, that he painted, it is said, in a few weeks an entire hall in the Vitelli palace at Città di Castello. Along with daring, he had fertility of combination, and in works of parade he attained a certain measure of success, although his drawing was incorrect and his mannerism palpable. He belongs to the degenerate period of the Bolognese school, under the influence chiefly of the imitators of Raphael—Sabbatini, Sammachini and Passerotti being three of his principal colleagues. His soundest successes were in portraiture, in which branch of art he stood so high that towards 1550 Michelangelo introduced him to Pope Julius III. as a portrait-painter; and he was pensioned by this pope, and remained in his favour until the death of the three successors of Julius. Here he lived on a grand scale, and figured as a sort of arbiter and oracle among his
professional brethren. Returning to Bologna, after doing some work in Fontainebleau and in Genoa, he opened a school of art, in which he became the preceptor of Lodovico and Agostino Carracci; but these pupils, standing forth as reformers and innovators, finally extinguished the academy and the vogue of Fontana. His subjects were in the way of sacred and profane history and of fable. He has left a large quantity of work in Bologna,—the picture of the "Adoration of the Magi," in the church of S. Maria delle Grazie, being considered his masterpiece—not unlike the style of Paul Veronese. He died in Rome in 1597.

FONTEANE, THEODOR (1819-1898), German poet and novelist, was born at Neu-Ruppin on the 30th of December 1819. At the age of sixteen he was apprenticed to a chemist, and after qualifying as an apothecary, he found employment in Leipzig and Dresden. In 1844 he travelled in England, and settling in Berlin devoted himself from 1849 to literature. He made repeated journeys to England, interesting himself in old English ballads, and as the firstfruits of his tours published Ein Sommer in London (1854); Aus England, Studien und Briefe (1860) and Jenselt des Zweed, Bilder und Briefe aus Schottland (1860). Fontane was particularly attached to the Mark of Brandenburg, in which he was particularly interested, and delighted in the growth of the capital city, Berlin. The fascination which the country of his birth had for him may be seen in his delightfully picturesque Wanderungen durch die Mark Brandenburg (1862-1882, 4 vols.). He also described the wars of Prussia in Der schleswig-holsteinische Krieg im Jahre 1864 (1866) and Der deutsche Krieg von 1866 (1869). He proceeded to the theatre of war in 1870, and, being taken prisoner at Vauxvillers, remained three months in captivity. His experiences he narrates in Kriegsgefangen. Erlebtes 1870 (1871), and he published the result of his observations of the campaign in Der Krieg gegen Frankreich 1870-71 (1874-1876). Like most of his contemporaries, he at first sought inspiration for his poetry in the heroes of other countries. His Gedichte (1851) and Balladen Manner und Helden (1860) tell of England's glories in bygone days. Then the achievements of his own countrymen entered into rivalry, and these, as an ardent patriot, he immortalized in poem and narrative. It is, however, as a novelist that Fontane is best known.

His fine historical romance Vor dem Sturm (1878) was followed by 3 series of novels of modern life: L'Adultera (1884); Schach von Wuthenau (1888); Irrungen, Wirrungen (1888); Sturm (1890); Unwiederbringlich (1891); Eff Briex (1893); Der Stechlin (1895), in which with fine literary tact Fontane adapted the realistic methods and social criticism of contemporary French fiction to the conditions of Prussian life. He died on the 20th of September 1898 at Berlin.

Fontane's Gesammelte Romane und Erzahlungen were published in 12 vols. (1890-1891: 2nd ed., 1905). For his life see the autobiographical works Meine Kinderjahre (1894) and Von zwanzig bis dreissig (1898), also Briefe an seine Familie (1905); also F. Servaes, Theodor Fontane (1900).

FONTEANE, LOUIS, MARQUIS DE (1757-1821), French poet and politician, was born at Nantes (Deux-Sèvres) on the 6th of March 1757. He belonged to a noble Protestant family of Languedoc which had been reduced to poverty by the revocation of the edict of Nantes. His father and grandfather remained Protestant, but he himself brought up as a Catholic. His parents died in 1774-1775, and in 1777 Fontane went to Paris, where he found a friend in the dramatist J. F. Ducis. His first published poems, some of which were inspired by English models, appeared in the Almanach des Muses; "Le Cri de mon cœur," describing his own sad childhood, in 1778; and "La Forêt de Navarre" in 1780. His translation from Alexander Pope, L'Essai sur l'homme, was published with an elaborate preface in 1783, and La Chariteuse and Le Jour des morts in the same year, Le Verger in 1788 and his Épître sur l'édit en faveur des non-catholiques, and the Essai sur l'astronomie in 1789. Fontane was a moderate reformer, and in 1790 he became joint-editor of the Moderateur. He married at Lyons in 1792, and his wife's first child was born during their flight from the siege of that town. Fontane was in hiding in Paris when the four citizens of Lyons were sent to the Convention to protest against the cruelties of Collot d'Herbois. The petition was drawn up by Fontanes, and the authorship being discovered, he fled from Paris and found shelter at Sevrn, near Livry, and afterwards at Andelys. On the fall of Robespierre he was made professor of literature in the Ecole Centrale des Quatre-Nations, and he was one of the original members of the Institute. In the Memoral, a journal edited by La Harpe, he discreetly advocated reaction to the monarchical principle. He was exiled by the Directory and made his way to London, where he was closely associated with Chateaubriand. He soon returned to France, and his admiration for Napoleon, who could write an illoge on Washington, secured his return to the Institute and his political promotion. In 1802 he was elected to the legislative chamber, of which he was president from 1802 to 1810. Other honours and titles followed. He has been accused of servility to Napoleon, but he had the courage to remonstrate with him on the judicial murder of the duc d'Enghien, and as grand master of the university of Paris (1858-1853) he consistently supported religious and monarchical principles. He acquired the gardens of Châteauvillain, and was made a marquis of the Empire. He died at Neu-Ruppin in January 1821. leaving eight cantos of an unfinished epic poem entitled La Grece sauvete.

The verse of Fontanes is polished and musical in the style of the 18th century. It was not collected until 1839, when Sainte-Beuve edited the Oeuvres (2 vols.) of Fontanes, with a sympathetic critical study of the author and his work. But by that time the Romantic movement was in the ascendant and Fontanes met with small appreciation.

FONTENAY-LE-COMTE, a town of western France, capital of an arrondissement in the department of Vendée 50 m. N.E. of Nantes, on the Sèvre, is situated on the railway between that town and Saumur. Pop. (1906) town, 76,393; commune, 10,226. Fontenay, an ancient and straggling town, is situated a few miles south of the forest of Vouvant and on both banks of the Vendée, at the point where it becomes navigable. The church of Notre-Dame (15th to 16th centuries), which has a fine spire and a richly sculptured western entrance, and the church of St Jean (16th and 17th centuries) are the chief religious buildings. The town has several houses of the 16th and 17th centuries. The most remarkable of these is the Hôtel de Terre Neuve (1595-1660), which contains magnificent decoration together with collections of furniture and tapestry. Fontenay was the birthplace of many prominent men during the 15th and 16th centuries, and the Fontaine des Quatre-Tins, a fountain in the Renaissance style, given to the town by King Francis I, commemorates the fact. The chief square is named after François Viète, the great mathematician, who was born at Fontenay in 1540. The public institutions of the town include a tribunal of first instance and a communal college. Among its industries are the manufacture of felt hats, oil and soap and timber-sawing, flour-milling and tanning. There is trade in horses, mules, timber, grain, fruit, &c.

Fontenay was in existence as early as the time of the Gauls. The affix of "comte" is said to have been applied to it when it was taken by King Louis IX. from the family of Lusignan and given to his brother Alphonse, count of Poitou, under whom it became capital of Bas-Poitou. Ceded to the English by the treaty of Brétigny in 1360 it was retaken in 1372 by Duqueslin. It suffered repeated capture during the Religious Wars of the 16th century, was disembarked in 1621 and was occupied both by the republicans and the Vendéens in the war of 1793. From 1794 to 1806 it was capital of the department of Vendée.

FONTENELLE, BERNARD LE BOVIER DE (1657-1757), French author, was born at Rouen, on the 11th of February 1657. He died in Paris, on the 9th of January 1757, having thus very nearly attained the age of 100 years. His father was an advocate settled in Rouen, his mother a sister of the two Corneilles. He was educated at the college of the Jesuits in his native city, and distinguished himself by the extraordinary precocity and versatility of his talents. His teachers, who readily appreciated these, were anxious for him to join their
order, but his father had designed him for the bar, and an advocate accordingly he became; but, having lost the first cause which was entrusted to him, he soon abandoned law and gave himself wholly to literary pursuits. His attention was first directed to poetry; and more than once he competed for prizes of the French Academy, but never with success. He visited Paris from time to time and established intimate relations with the abbe de Saint Pierre, the abbe Vertot and the mathematician Pierre Varignon. He witnessed, in 1680, the total failure of his tragedy Aspas. Fontenelle afterwards acknowledged the justice of the public verdict by burning his unfortunate drama. His opera de Thèbès et Pélée, 1680, though highly praised by Voltaire, cannot be said to rise much above the others; and it may be regarded as significant that of all his dramatic works not one has kept the stage. His Poésies pastorales (1688) have no greater claim to permanent repute, being characterized by stiffness and affectation; and the utmost that can be said for his poetry in general is that it displays much of the limaee labor, great purity of diction and occasional felicity of expression.

His Lettres galantes du chevalier d’Her . . . , published anonymously in 1685, was an amusing collection of stories that immediately made its mark. In 1686 his famous allegory of Rome and Geneva, slightly disguised as the rival princesses Mreo and Eneug, in the Relation de l’ile de Bornéo, gave proof of his daring in religious matters. But it was by his Nouveaux Dialogues des morts (1683) that Fontenelle established a genuine claim to high literary rank; and that claim was enhanced three years later by the appearance of the Entretiens sur la pluralité des mondes (1686), a work which was among the very first to illustrate the possibility of being scientific without being either uninteresting or unintelligible to the ordinary reader.

His object was to popularize among his countrymen the astronomical theories of Descartes; and it may well be doubted if that philosopher ever ranked a more ingenious or successful expositor among his disciples.

Hitherto Fontenelle had made his home in Rouen, but in 1687 he removed to Paris; and in the same year he published his Histoire des oracles, a book which made a considerable stir in theological and philosophical circles. It consisted of two essays, the first of which was designed to prove that oracles were not given by the supernatural agency of demons, and the second that they did not cease with the birth of Christ. It excited the suspicion of the Church, and a Jesuit, by name Baltus, published a ponderous refutation of it; but the peace-loving disposition of its author impelled him to leave his opponent unanswered.

Towards the following year (1688) belongs his Digression sur les anciens et les modernes, in which he took the modern side in the controversy then raging; his Douze sur le système physique des causes occasionnelles (against Malebranche) appeared shortly afterwards.

In 1691 he was received into the French Academy in spite of the determined efforts of the partisans of the ancients in this quarrel, especially of Racine and Boileau, who on four previous occasions had secured his rejection. He consequently was admitted a member both of the Academy of Inscriptions and of the Academy of Sciences; and in 1697 he became perpetual secretary to the latter body. This office he actually held for the long period of forty-two years; and it was in this official capacity that he wrote the Histoire du renouvellement de l’Académie des Sciences (Paris, 3 vols., 1708, 1717, 1722) containing extracts and analyses of the proceedings, and also the éloges of the members, written with great simplicity and delicacy. Perhaps the best known of his éloges, of which there are sixty-nine in all, is that of his uncle Pierre Corneille. This was first printed in the Nouvelles de la république des lettres (January 1668) and, as Vie de Corneille, was included in all the editions of Fontenelle’s Œuvres. The other important works of Fontenelle are his Éléments de la géométrie de Platon (1727) and his Apologie des idéalistes (1757). Fontenelle forms a link between two very widely different periods of French literature, that of Corneille, Racine and Boileau on the one hand, and that of Voltaire, D’Alembert and Diderot on the other. It is not in virtue of his great age alone that this can be said of him; he actually had much in common with the beaux esprits of the 17th century, as well as with the philosophes of the 18th. But it is to the latter rather than to the former period that he properly belongs.

He has no claim to be regarded as a genius; but, as Sainte-Beuve has said, he well deserves a place “dans la classe des esprits infiniment distingués”—distinguished, however, it ought to be added by intelligence rather than by intellect, and less by the power of saying much than by the power of saying a little well. His personal character has sometimes been described as having been rebelliously heartless; and it is abundantly plain that he was singularly incapable of feeling strongly the more generous emotions—a misfortune, or a fault, which revealed itself in many ways. “Il faut avoir de l’amour pour avoir du goût.” But the cynical expressions of such a man are not to be taken too literally; and the mere fact that he lived and died in the esteem of many friends suffices to show that the theoretical self-sufficiency which he sometimes professed cannot have been consistently and at all times carried into practice.

There have been several collective editions of Fontenelle’s works, the first being printed in 3 vols. at the Hague in 1728–1729. The best is that of Paris, in 8 vols. 8vo, 1790. Some of his separate works have been very frequently reprinted and also translated. The Livre des mondes was repeated in many languages. Sainte-Beuve has an interesting essay on Fontenelle, with several useful references, in the Coursiers du lundi, vol. iii. See also Villemeur de la Ville, Dictionnaire historique et philosophique de Trublet, Mémoires pour servir à l’histoire de la vie et des ouvrages de M. de Fontenelle (1759); A. Laborde-Milah, Fontenelle (1905), the third, “Grands écrivains français” series; and L. Maignon, Fontenelle, l’homme, l’auteur, l’influence (Paris, 1906).

FONTENOY, a village of Belgium, in the province of Henneau, about 4 m. S.E. of Tournai, famous as the scene of the battle of Fontenoy, in which on the 11th of May 1745 the French army under Marshal Saxe defeated the Anglo-Allied army under the Duke of Cumberland. The object of the French (see also AUSTRIAN SUCCESSION, WAR OF THE) was to cover the siege of the then important fortress of Tournai, that of the Allies, who slowly advanced from the east, to relieve it. Informed of the impending attack, Louis XV., with the dauphin, came with all speed to witness the operations, and by his presence to give Saxe, who was in bad health and beset with private enemies, the support necessary to enable him to command effectively.

Under Cumberland served the Austrian field-marshal Königsegg, and, at the head of the Dutch contingent, the prince of Waldeck.

The right of the French position (see map) rested on the river at Antoing, which village was fortified and garrisoned, between Antoing and Fontenoy three square redoubts were constructed, and Fontenoy itself was put in a complete state of defence. On the 7th of May these lines of defense were separated from Fontenoy by some furlongs of open ground, another redoubt was made at the corner of the wood of Barry and a fifth towards Gavrain. The infantry was arrayed in deployed lines behind the Antoing-Fontenoy redoubts and the low ridge between Fontenoy and the wood; behind them was the cavalry. The approaches to Gavrain were guarded by a mounted volunteer corps called Grassins. At Calonne the marshal had constructed three military bridges against the contingency of a forced retreat. The force of the French army was about 60,000 men, and separated from Fontenoy by some 2,000 yards. The French with advantage the Grand Saxe had been unable to mount his horse, slept in a wicker chariot in the midst of the troops. At early dawn of the 11th of May, the Anglo-Hanoverian army with the Austrian contingent formed up in front of Vézon, facing towards Fontenoy and the wood, while the Dutch on their left extended the general line to Péronne. The total force was 46,000, against about 52,000 whom Saxe could actually put into the field.

The plan of attack arranged by Cumberland, Königsegg and Waldeck on the roth grew out of circumstances. A preliminary skirmish had cleared the broken ground immediately in front of Vézon and revealed a part of the defender’s dispositions. It was resolved that the Dutch should attack the front Antoing—
Fontenoy, while Cumberland should deliver a flank attack against Fontenoy and all in rear of it, by way of the open ground between Fontenoy and the wood. A great cavalry attack round the wood was projected but had to be given up, as in the late evening of the 9th the Allies' light cavalry drew fire from its southern edge. Cumberland then ordered his cavalry commander to form a screen facing Fontenoy, so as to cover the formation of the infantry. On the morning of the 10th another and most important modification had to be made. The advance was beginning when the redoubt at the corner of the wood became visible. Cumberland hastily told off Brigadier James Ingoldsby (major and brevet-colonel 1st Guards), with four regiments and an artillery detachment, to storm this redoubt which, crossing its fire with that of Fontenoy, seemed absolutely to inhibit the development of the flank attack. At 6 A.M. the brigade moved off, but it was irresolutely handled and halted time after time; and after waiting as long as possible, the British and Hanoverian cavalry under Sir James Campbell rode forward and extended in the plain, becoming at once the target for a furious cannonade which killed their leader and drove them back. Thereupon Sir John (Lord) Ligonier, whose deployment the squadrons were to have covered, let them pass to the rear, and, hearing the guns of the Dutch towards Antoing, pushed the British infantry forward through the lanes, each unit on reaching open ground covering the exit and deployment of the one in rear, all under the French cannonade. This went on for two hours, and save that it showed the magnificent discipline of the British and Hanoverian regiments, was a bad prelude to the real attack. Cumberland's own exertions brought a few small guns to the front of the Guards' Brigade, and one of the first shots from these killed Antoine Louis, due de Gramont, colonel of the Gardes Françaises, and another Henri du Baraillon du Brocad, Saxe's artillery commander.

It was now 9 A.M., and while the guns from the wood redoubt battered the upright ranks of the Allies, Ingoldsby's brigade was huddled together, motionless, on the right. Cumberland himself galloped thither, and under his reproaches Ingoldsby lost the last remnants of self-possession. To Sir John Ligonier's aide-de-camp, who delivered soon afterwards a bitterly formal order to advance, Ingoldsby sullenly replied that the duke's orders were for him to advance in line with Ligonier's main body.

By now, too, the Dutch advance against Antoing-Fontenoy had collapsed.

But on the right the cannonade and the blunders together had roused a stern and almost blind anger in the leaders and the men they led. Ingoldsby was wounded, and his successor, the Hanoverian general Zastrow, gave up the right attack and brought his battalions into the main body. A second half-hearted attack on Fontenoy itself, delivered by some Dutch units, was almost as successful as the value of two of these battalions (one of them being the then newly raised Highland regiment, the Black Watch) which came thither of their own accord. Meanwhile the young duke and the old Austrian field-marshall had agreed to take all risks and to storm through between Fontenoy and the wood redoubt, and had launched the great attack, one of the most celebrated in the history of war. The English infantry was in two lines. The Hanoverians on their left, owing to want of space, were compelled to file into third line behind the redcoats, and on their outer flanks were the battalions that had been with Ingoldsby. A few guns, man-drawn, accompanied the assaulting mass, and the cavalry followed. The column may have numbered 14,000 infantry. All the infantry battalions closed on their centre, the normal three ranks becoming six. If the proper distances between lines were preserved, the mass must have formed an oblong about 500 yards by 600 yards (excluding the cavalry).

The duke of Cumberland placed himself at the head of the front line and gave the signal to advance. Slowly and in parade order, drums beating and colours flying, the mass advanced, straight up the gentle slope, which was swept everywhere by the flanking artillery of the defence. Then, when the first line reached the low crest on the ends of which stood the French artillery, the fire, hitherto convergent, became a full enfilade from both sides, and at the same moment the enemy's horse and foot became visible beyond. A brief pause ensued, and the front gradually contracted as regiments shouldered inwards to avoid the fire. Then the French advanced, and the Guards Brigade and the Gardes Françaises met face to face. Captain Lord Charles Hay (d. 1760), lieutenant of the First (Grenadier) Guards, suddenly ran in front of the line, took off his hat to the enemy and drank to them from a pocket flaske, shouting a taunt, "We hope you will stand till we come up to you, and not swim the river as you did at Dettingen," then, turning to his own men, he called for three cheers. The astonished French officers returned the salute and gave a ragged counter-cheer. Whether or not the French, as legend states, were asked and refused to fire first, the whole British line fired one tremendous series of volleys by companies. 50 officers and 760 men of the three foremost French regiments fell at once, and at so appalling a loss the remnant broke and fled. Three hundred paces farther on stood the second line of the French, and slowly the French advanced, firing regular volleys. It was now well inside the French position, and no longer felt the enfilade fire that swept the crest it had passed over. By now, as the rear lines closed up, the assailants were practically in square and repelled various partial attacks coming from all sides. The Régiment du Roi lost 33 officers and 345 men at the hands of the Second (Coldstream) Guards. But these counter-attacks gained a few precious minutes for the French. It was the crisis of the battle. The King, though the court mediated flight, stood steady with the dauphin at his side,—Fontenoy was the great day of Louis XV.'s life,—and Saxe, ill as he was, mounted his horse to collect his cavalry for a charge. The British and Hanoverians were now at a standstill. More and heavier counter-strokes were repulsed, but no progress was made; their cavalry was unable to get to the front, and Saxe was by now thinking of victory. Captain Inuard of the Touraine regiment suggested artillery to batter the face of the square, preparatory to a final charge. General Löwendahl galloped up to Saxe, crying, "This is a great day for the king; they will never escape!" The nearest guns, one of the 36-pounders, he assaulted a flanking redoubt. The infantry, led by Löwendahl, fastened itself on the sides of the square, the regiments of Normandy and Vaiseaux and the
Irish Brigade conspicuous above the rest. On the front, waiting for the cannon to do its work, were the Maison du Roi, the Gendarmerie and all the light cavalry, under Saxe himself, the duke of Richelieu and count d’Estrees. The left wing of the Allies was still inactive, and troops were brought up from Antoing and Fontenoy to support the final blow. About 2 P.M. it was delivered, and in eight minutes the square was broken. As the infantry retired across the plain in small stubborn groups the French fire still made havoc in their ranks, but all attempts to close with them were repulsed by the terrible volleys, and they regained the broken ground about Vezon, whence they had come. Cumberland himself and all the senior generals remained with the rearguard.

The losses at Fontenoy were, as might be expected, somewhat less than normally heavy when distributed over the whole of both armies, but exceedingly severe in the units really engaged. Eight out of nineteen regiments of British infantry lost over 200 men, two of these more than 300. A tribute to the loyalty and discipline of the British, as compared with the generality of armies in those days, may be found in the fact that the three Guards’ regiments had no “missing” men whatever. The 23rd (Royal Welsh Fusiliers) had 322 casualties. Boshlanger’s Hanoverian regiment suffered even more heavily, and four others of that nation had 200 or more casualties. The total loss was about 7500, that of the French 7000. The French “Royal” regiment lost 30 officers and 645 men; some other regimental casualties have been mentioned above. The Dutch lost a bare 7% of their strength.

Fontenoy was in the 18th century what the attack of the Prussian Guards at St Privat is to-day, a focus classicus for military theorists. But the technical features of the battle are completely overshadowed by its epic interest, and above all it illustrates the permanent and unchangeable military characteristics of the British and French nations.

Fontenoy, or FONTEVRAULT (Lat. Fundo Ebraldi), a town of western France, in the department of Maine-et-Loire, 10 m. S.E. of Saumur by road and 2½ m. from the confluence of the Loire and Vienne. Pop. (1806) 1279. It is situated in the midst of the forest of Fontevrault. The interest of the place centres in its abbey, which since 1804 has been utilized and abused as a central house of detention for convicts. The church (12th century), of which only the choir and apse are appropriated to divine service, has a beautiful nave formerly covered by four cupolas destroyed in 1516. There is a fine roof of 17th-century beams. In a chapel in the south transept are the effigies of Henry II. of England, of his wife Eleanor of Guinene, of Richard I. of England, and of Isabella of Angouleme, wife of John of England—Eleanor’s being of oak and the rest of stone. The cloister, refectory and chapter-house date from the 17th century. The second court of the abbey contains a remarkable building, the Tour d’Evrault (12th century), which long went under the misnomer of chapelle funéraire, but was in reality the old kitchen. Details and diagrams will be found in Viollet-le-Duc’s Dictionnaire de l’architecture. There are three stories, the whole being surmounted by a pyramidal structure.

The Order of Fontevrault was founded about 1100 by Robert of Arbrissel, who was born in the village of Arbrissel or Arbrhese, in the diocese of Rennes, and attained great fame as a preacher and ascetic. The establishment was a double monastery, containing a nunnery of 300 nuns and a monastery of 200 monks, separated completely so that no communication was allowed except in the church, where the services were carried on in common; there were, moreover, a hospital for 120 lepers and other sick, and a hospital for fallen women, both worked by the nuns. The basis of the life was the Benedictine rule, but the observance of abstinence and silence went beyond it in stringency. The special feature of the institute was that the abbess ruled the monks as well as the nuns. At the beginning the order had a great vogue, and at the time of Robert’s death, 1217, there were several monasteries and 3000 nuns; afterwards the number of monasteries reached 57, all organized on the same plan. The institute never threw out of France; there were attempts to introduce it into Spain and England; in England there were three houses—at Ambresbury (Ambersbury in Wiltshire), Nuneaton, and Westwood in Worcestershire. The nuns in England as in France were recruited from the highest families, and the abbess of Fontevrault, who was the superior-general of the whole order, was usually of the royal family of France.

Hillen, Hist. des ordres religieux (1718), vi. cc. 12, 13; Max Heimbucher, Ordens und Kongregationen (1867), i. 46; the arts. “Fontevrault” in Wetzer and Welte, Kirchenlexicon (ed. 2), and in Herzog-Hauck, Realencyclopädie (ed. 3), supply full references to the literature. The most recent monograph is Ernst von Fontevrault et ses monuments (1875); for the later history see art. by Edmund Bishop in Downside Review (1886).

FOODE—The food of a normal diet upon the health of man (we exclude here the question of diet in illness, which must depend on the abnormal conditions existing) begins at the earliest stage of his life. No food has as yet been found so suitable for the young of all animals as their mother’s milk. This, however, has not been from want of seeking. Dr. Brouzet (Sur l’éducation médicale des enfants, i. p. 165) has had such a bad opinion of human mothers that he considers it wrong for the state to interfere and prevent them from sucking their children, and that they should communicate immorality and disease! A still more determined pessimist was the famous chemist Van Helmont, who thought life had been reduced to its present shortness by our inborn propensities, and proposed to substitute bread boiled in beer and honey for milk, which latter he calls “brute’s food.” Baron Justus von Liebig, as the result of his chemical researches, introduced a “food for infants,” which in more modern days has been followed by a multiplication of patent foods. A close observation of human milk may also be made by the addition to fresh cow’s milk of half its bulk of sweet water, in each pint of which has been mixed a heaped-up teaspoonful of powdered “sugar of milk” and a pinch of phosphate of lime. These artificial substitutes for the natural nutrient have their value where for any reason it is not available. The wholesomest food, however, for the first six months is certainly mother’s milk alone. A vigorous baby can indeed bear with impunity much rough usage, and often appears none the worse for a certain quantity of blue milk. The majority of cows must be milked and the milk, at least, its strong part, put out without an exhibition of dislike which indicates rebellion of the bowels. It is only when the teeth are on their way to the front, as shown by dribbling, that the parotid glands secrete an active saliva capable of digesting bread stuffs. Till then anything but milk must be given tentatively, and considered in the light of a means of education for its future mode of nutrition.

The time for weaning should be fixed partly by the child’s age, partly by the growth of the teeth. The first group of teeth nine months out of ten consists of the lower central front teeth, which may appear any time during the sixth and seventh month. The mother may then begin to diminish the number of suckling times; and by a month she can have reduced them to twice a day, so as to be ready when the second group makes its way through the upper front gums to cut off the supply altogether. The third group, the lateral incisors and first canines, usually after the first anniversary of birth, give notice that solid food can be chewed. But it is prudent to let dairy milk form a considerable portion of the fare till the eye-teeth are cut, which seldom happens till the eighteenth or twentieth month.

Childhood and Youth.—At this stage of life the diet must obviously be the best which is a transition from that of infancy to that of adult age. Growth is not completed, but yet entire surrender of every consideration to the claim of growth is not possible, nor indeed desirable. Moreover, that abundance of adipose tissue, or reserve new growth, which a baby can bear is an impediment to the due education of the muscles of the boy or girl. The supply of nutritious food need not be so continuous as before, but at the same time should be more frequent than for
the adult. Up to at least fourteen or fifteen years of age the rule should be four meals a day, varied indeed, but nearly equal in nutritive power and in quantity, that is to say, all moderate, all sufficient. The maturity the body then reaches involves a hardening and enlargement of the bones and cartilages, and a strengthening of the digestive organs, which in healthy young persons enables us to dispense with some of the watchful care bestowed upon their diet. Three full meals a day are generally sufficient, and the requirements of mental training may be allowed to a certain extent to modify the attention to nutrition which has hitherto been paramount.

Adults.—It is only necessary here to refer to the article on DIETETICS (see also VEGETARIANISM) for a discussion of the food of normal adults, and to such headings as DIETETICS: Food and its Functions (1895).

FOOD PRESERVATION. The preservation of food material beyond the short term during which it naturally keeps sound and estable has been accomplished through the centuries, and has been a civilization. Necessity compelled man to store the plentitude of one season or place against the need of another. The hunter dried, smoked and salted meat and fish, pastoral man preserved milk in the form of cheese and butter, or fermented grape-juice into wine. With the separation of country from town, the development of manufacturing nation as distinct from agricultural and food-producing people, the spreading of civilized man from torrid to arctic zones, the needs of travellers on land and sea and of armies on the march, the problem of the prevention of the natural decomposition to which nearly all food substances are liable, and of the astonishingly numerous attempts to check the production of food, the most important problem in connexion with the feeding and the trade of nations. As long as the reasons of decomposition were unknown, all attempts at preservation were necessarily empirical, and of the numberless processes which have during modern times been proposed and attempted comparatively few have stood the test of experience. In the light of modern knowledge, however, the guiding principles appear to be very simple.

Very few organic materials undergo decomposition, as it were, of their own accord. They may lose water by evaporation, and fatty substances may alter by the absorption of oxygen from the air. They are otherwise quite stable and unchangeable while not attacked and eaten up by living organisms, or while the life with which they may be endowed is in a state of suspense. An apple is alive and in breathing undergoes its ripening change; a grain of wheat is dormant and does not alter. A substance, in order to be a food material, must be decomposable under the attack of a living organism; the energy stored in it must be available to that stream of energy which we call life, whether the life be in the form of the human consumer or of any lower organism. All decomposition of food is due to the development within the food of living organisms. Under conditions under which living organisms cannot enter or cannot develop food keeps undecomposed for an indefinite length of time. The problem of food preservation resolves itself, therefore, into that of keeping out or killing off all living things that might feed upon and thus alter the food, and as these organisms mainly belong to the family of moulds, yeasts and bacteria, modern food preservation is strictly a subject for the bacteriologist.

The changes which food undergoes on keeping, and particularly to the air, or by the presence of agents inhibiting their growth though not destroying their life. All successful processes of food preservation depend upon one or other of these circumstances.

Preservation by Heat.—At the boiling-point of water all living things perish, but some spores of bacteria may survive for about three hours. Few lives have in the presence of water, though dry heat only kills with certainty at 140°F. (284°F). Destruction of life takes place more rapidly in solutions showing an acid than a feebly alkaline reaction; hence acid fruit is more easily preserved than milk, which, when quite fresh, is alkaline. By cooking, therefore, food becomes temporarily sterile, until a fresh crop of organisms finds access from the air. By repeated cooking all food can be indefinitely preserved. One of the most important functions of cookery is sterilization. Civilized man unwittingly revolts against his food. Cooking constitutes a large part of the processing of food, and the certain fungus-infected material is an inheritance from barbarous ages; few materials of animal origin are eaten raw, and vegetables some sort of sterilizing process is attempted by washing (of salads) or removal of the outer skin (of fruits).

The preparation of food for the table, cooking being the most important, tends towards preservation, but is effectual only for a few hours or days at most, unless special means are adopted to prevent re-infection. The housewife covering the jam with a thin paper soaked in brandy, or the potted meat with a thin layer of lard, attempts to harden the food, and to prevent the evaporation of water, thereby increasing the resistance of the food to the invasion of new organisms. To preserve food in a permanent manner and on a commercial scale it has to be cooked in a receptacle which must be sufficiently strong for transport, cheap, light and unattacked by the material in contact with it. None of the receptacles at present in use quite fulfils the whole of these conditions: glass and china are heavy and fragile, and their carriage is expensive; tinned iron, so-called tin-plate, is rarely quite unaffected by food materials, but owing to its strength, tenacity and cheapness, it is used on an ever-increasing scale. The sheet iron, which formerly was made of soft wrought iron, now generally consists of steel containing but very little carbon; it is cleaned by immersion in acid and covered with a very thin layer of pure tin, all excess of tin being removed by hot rollers and brushes. The layer of tin, which formerly constituted from 3 to 5% of the total weight of the plate, has, owing to the increased price of tin and the improvement in machinery, gradually become so thin that its weight is only from 1 to 3%. Not rarely, therefore, the tin-surface is imperfect, perforated or pin-holed. Tin itself is slightly attacked by all acids excepting water, but it is permeated by fat, fish and vegetable or animal substances. With the exception of milk, all human food is slightly acid, and consequently all food that has been preserved in tin canisters contains variable traces of dissolved tin. Happily, salts of tin have but little physiological action. Nevertheless, the employment of tin-plate for very acid materials, like tomatoes, peaches, &c., is very objectionable.

The process of preservation in canisters is carried out as
follows.—The canister, which has been made either by the use of solder or by folding machinery only, is packed with the material to be preserved, and a little water having been added to fill the interstices the lid is secured by soldering or folding similar to the former. Sterilization is effected by placing the tins in pressure chambers, which are heated by steam to 120° C. or more. The tins are exposed to that temperature for such time as experience has shown to be necessary to heat the contents throughout to at least 100° C. The temperature is then allowed to fall slowly to below the boiling-point of water, when the tins can be taken out of the pressure chamber, or they are placed in a bath filled with water or a solution of calcium chloride and are therein held hot till thoroughly cool. Sometimes the aperture is pierced through the lid, to allow of the escape of the expanding air, such holes before cooling closed by means of a drop of solder. This process, which was originally introduced by Francois Appert early in the 19th century, is employed on an enormous scale, especially in America. The use of lacquered tins, having the inner surface of the tin covered with a heat-resisting varnish, is gradually extending. Imperfect sterilization shows itself in many cases by gas development within the tin, which causes the ends to become convex and drummed. Occasionally, though not in the contents of the larger tins, containing meat or other animal products, are not absolutely sterile, but the conditions are mostly such that the organisms which have survived the cooking process cannot develop. When they can develop without formation of gas dangerous products of decomposition may be produced without showing themselves to taste or smell. Numerous cases of so-called ptomaine poisoning have thus occurred; these are more frequently associated with preserved fish and lobster than with meats, although no class of preserved animal food is free from liability of ptomaine formation. The formation of poisonous substances has never been traced to preserved fruit or other material poor in nitrogen. The mode of preserving food in china or glass is quite similar, but the losses by breakage are not inconsiderable. Food which has been preserved in tins is sometimes transferred to glass and re-sterilized, the feeling against “tinned” food caused by the “Chicago scandals” not having entirely subsided. Were it not for the facts that sterilization is rarely quite perfect, and that the food attacks the tin, the contents of tin canisters ought to keep for an indefinite length of time. Under existing circumstances, however, there is a distinct limit to the age of soundness of canned food.

Preservation by Chemicals.—Salt is the oldest chemical preservative and, either alone or in conjunction with saltpetre and with wood-smoke, has been used for many centuries, mainly as a meat preservative. It is used either dry in layers strewn on the surface of the meat or fish to be preserved, or in the form of brine in which the meat is submerged or which is injected into the carcasses. The preserving power of salt is but moderate. It has the great advantage that in ordinary doses it is non-injurious, that an excess at once betrays itself in the taste, and that it can be readily removed by soaking in water. When aided by wood-smoke, which depends for its preservative power upon traces of cresote and formaldehyde, it is, however, quite efficient. The addition of saltpetre is principally for the purpose of giving to the meat a bright pink tint. The strongly saline taste of pickled meat or salted butter appears gradually to have become repugnant to a large part of mankind, and other preservatives have come into use, possessing greater bactericidal power and less taste. The serious objection attaching to them is discussed in the article ADULTERATION. At the present time the use of borax or boric acid is almost universal in England. Meat which has been exposed to the vapours of formaldehyde, and has thus been superficially sterilized, is also coming into commerce in increasing quantities. Formaldehyde in itself is distinctly poisonous, and has the property of combining with albuminoids and rendering them completely insoluble in the digestive secretions. Salicylic and benzoic acids are not infrequently used to stop fermentation of saccharine beverages or deterioration of so-called “potted meats,” which are supposed to last fresh and sweet on the consumer’s table for a considerable length of time. Sulphurous acid and sulphites are chiefly used in the preservation of thin ales, wine and fruit, and sodium fluorides are found in butter. The whole of these substances are, however, decided and dangerous physiological poisons. Andis, now, rarely forms a preservative of food material, its employment being confined to small fruit. The use of sugar as a preservative depends upon the fact that, although in a dilute solution it is highly prone to fermentation and other decomposition, it possesses bactericidal properties when in the form of a concentrated syrup. A sugar solution containing 30% of water or less does not undergo any biological change; in the presence of organic acids, like those contained in fruit, growth of organisms is extinguished when the percentage of water is somewhat greater. Upon this fact depends the use of sugar in the manufacture of jams, marmalades and jellies. Moulds may grow on the surface of such saccharine preparations, but the interior remains unaffected and unaltered.

Preservation by Drying.—Food materials in which the percentage of moisture is small (not exceeding about 8%) are but little liable to bacterial growths, at most to the attacks of innocent Penicillium. Nature preserves the germs in seeds and nuts, which are killed with otherwise decomposable food material, by the simple expedient of water removal. The life of cereals, grains and many seeds appears to be unlimited. By the removal of water the most perishable materials, like meat or eggs, can be rendered unchangeable, except so far as the inevitable oxidation of the fatty substances contained in them is concerned, and which is independent of life-action. The drying of meat, upon which a generation ago inventors bestowed a great deal of attention, has become almost obsolete, except for comparatively small articles or animals, like ox tongues or tails and fish. It has been superseded even among less civilized communities by the spread of canned food. Fruit, however, is very largely preserved in the dried state. Grapes are sun-dried and thus form currants, raisins and sultanas, the last variety being often bleached by the addition of sulphites. Plums, apples and pears are artificially dried in ovens on wooden battens or on wire sieves; from the latter they are apt to become contaminated with notable quantities of zinc. Excellent preparations of dried vegetables, including potatoes, carrots, onions, French beans and callalooes, are also manufactured.

The utilization of meat in the form of meat extract belongs to some extent to this class of preserved foods. Its origin is due to J. von Liebig and Max von Pettenkofer, and dates from the middle of the 19th century. The soluble material is extracted mainly from beef in Australia to some extent from mutton, by means of warm water; the albumen is coagulated by heat and removed, and the broths thus obtained are evaporated in vacuo until the extract contains no more than about 20% of water. One pound of extract is obtained from about 25 lb of lean beef.

Preservation by Refrigeration.—At or below the freezing-point of water fungoid organisms are incapable of growth and multiplication. Although it has been asserted that many of them perish when kept for some time in the frozen condition, it is certain that the vast majority of bacteria and their germs remain merely dormant. Even so highly organized structures as cereal seeds do not suffer in vitality on being kept for a considerable length of time at the far lower temperature of liquid air. Biological change is, therefore, arrested at freezing-point, and as long as that temperature is maintained food material remains unaltered, except for physical changes depending upon the evaporation of water and of volatile flavouring matters, or chemical alterations due to oxidation.

Refrigeration, therefore, affords the means of keeping for a reasonably long time, and without the addition of any preservative substance, food in a raw condition. It is the only process of preservation which from a sanitary point of view is absolutely non-controversial and independent of any other employed. Its introduction on a commercial scale has more powerfully affected the economic conditions of England and, to a less degree,
FOOL

of the United States than any other scientific advance since the establishment of railways and steamboats. Enormous quantities of frozen carcasses, butter, fruit, vegetables and fish are introduced in the fresh condition into Great Britain and stored until required. Extreme fluctuations of supply or of price have become almost impossible, and the abundance of Australian and New Zealand ranches, and of West Indian orchards, has been made readily accessible to the British consumer. For household purposes cooling in ice-crests or ice-chambers suffices to preserve food on a comparatively small scale. The ice used for the purpose comes, to a small extent, from natural sources, stored from the winter or imported from northern countries; a far larger quantity is artificially produced by the methods described in the article on REFRIGERATING, which also contains an account of the means by which low temperatures are produced for industrial purposes of importation and storage. Fleets of steamships fitted with refrigerating machinery and insulated cold-rooms are employed in carrying the food materials, which are deposited in cold-stores at docks, warehouses, markets and hotels. The first cargo of frozen meat was shipped in July 1873 from Melbourne, but arrived in October in an unsatisfactory state. In 1875-1876 sound frozen meat came from America. The first cargo of frozen meat was successfully brought to the United Kingdom in 1880 from Australia in the "Strathleven," fitted with a Bell-Coleman air machine. The temperature in the cold-storage rooms is generally kept near 34° F., whilst in the chilling chambers a somewhat lower, and in the freezing room or chambers a much lower temperature (between 0° and 10° F.) is maintained. The carcasses of the frozen meat should be cooled slowly at first to ensure even freezing throughout and to prevent damage by the unequal expansion of the outer layer of ice. The carcasses when freezing must be hung separated from each other, but for storage or transportation they are packed tightly together. Fish such as salmon is washed, thoroughly cleansed, and frozen on trays. Butter should be cooled as rapidly as possible to about 10° F.; its composition as regards proportion of volatile fatty-acids, &c., remains absolutely unaltered for years. Cheese should only be cold-stored when nearly ripe and should not be frozen. Eggs must be carefully selected, each one being inspected by candle-light. They are placed in cases holding about three hundred, which are taken first to a room in which they are slowly cooled to about 35° F., and are then kept in store just below freezing-point. Particular attention must be paid to the relative humidity of the air in egg stores. Fruit should be quite fresh; grapes may be chilled to 26° F., while lemons cannot safely be kept at a lower temperature than 36°. The time during which soft fruit can be kept even in cold-store is limited, and does not exceed about six weeks.

The preservation of the dairy-milk trade considerable prejudice against stored meat. While in many cases the flavour of fresh meat is rather superior, the food value is in no way altered by cold-storage.2

Preservation by Pickling other than Salt.—For the preservation of vegetables, vinegar or other solution of acetic acid is used to a limited extent. Eggs are submerged in lime-water or a dilute solution of sodium silicate (soluble glass). During the storage of eggs the more aqueous white of egg yields by endosmosis a portion of its water to the more concentrated yolk, which thereby expands and renders thin the membrane liable to rupture. Fish, such as sardines, sprats and salmon, is preserved by packing in olive or other oil.

The preservation of the most important dairy product, namely, milk, deserves a separate notice. It has already been stated that alkaline liquids, like milk, are more difficult to sterilize than acid materials. In consequence of the alteration in flavour which milk undergoes by long continued boiling, and of the fact

that milk forms perhaps the best medium for the growth and propagation of bacterial organisms, there is exceptional difficulty in its sterilization. As secreted by a healthy cow it is a perfectly sterile fluid, and, as shown by Sir J. Lister, when drawn under aseptic conditions and kept under such, it remains definitely fresh and sweet. Bacterial and other pollution at the time of milking arises from the animal, the stable, the milker and the vessels. In animals suffering from tuberculosis and other bacterial infections the milk may be infected within the udder. Milk as it reaches the consumer rarely contains less than 40,000 bacteria and often many millions per cubic centimetre. In fresh country cream 100 millions per cubic centimetre are not unusual. These bacteria are of many kinds, some of them spore-bearing. The spores are more difficult to kill than the adult organism. The first step towards preservation is the removal of the dirt unavoidably present, to the particles of which a considerable proportion of the bacteria adhere. Filtration through cloths or, better, the passing of the milk through centrifugal effects that removal. Subsequent treatment is preferably preceded by a breaking-up of the larger fat-globules by the projection of a jet of the milk under high pressures against a steel or agate plate, a process known as homogenizing. From homogenized milk the cream separates slowly, and does not form the coherent layer thrown up by ordinary milk. Heating is then effected either after bottling or by passing the milk continuously through pipes in which it is heated to from 160° to 170° F. By a repetition of the heating process on two or more succeeding days, complete sterilization may be effected, although a single treatment is sufficient to render the milk stable for a few days. Many millions of pasteurizing apparatus for milk are in use. Since the general introduction of pasteurization of the skim-milk used in Denmark for the feeding of calves and pigs, tuberculosis in these animals has practically disappeared. On the continent of Europe the use of sterilized milk is now very general. In England it has found little favour in households, but is making rapid progress on board ship.

Milk which has been condensed has for many years found a most extensive sale. The first efforts to condense and thus preserve milk date from 1835, when an English patent was granted to Newton. In 1849 C. N. Horsford prepared condensed milk with the addition of lactose. Commercially successful milk condensation began in 1856. The milk is heated to about 180° F. and filled into large copper vacuum pans, after having been mixed with from 10 to 12 parts of sugar per 100 parts of milk. Evaporation takes place in the pans at about 125° F., and is carried on till the milk is boiled down to such concentration that 100 parts of the condensed milk, including the sugar, contain the solids of 300 parts of milk. Sweetened condensed milk, though rancid and tallowy, keeps indefinitely, and is invariably brought into commerce in tin cans. The preparation of sweetened condensed milk forms one of the most important branches of manufacture in Switzerland and is steadily increasing in England. Although milk can quite well be preserved in the form of condensed unsweetened milk, which dietetically possesses immense advantages over the sweetened milk in which the balance between carbohydrates and albuminoids is very unfavourable, such unsweetened milk has found little or no favour. Milk powder is manufactured under various patents, the most successful of which depends upon the addition of sodium bicarbonate and the subsequent rapid evaporation of the milk on steam-heated revolving iron cylinders. Milk powder made from skim-milk keeps well for considerable periods, but full-cream milk develops rancid or tallowy flavours by the oxidation of the finely divided butter-fat. It is largely employed in the preparation of so-called milk chocolates.

FOOL (O. Fr. fol, modern fou, foolish, from a Late Latin use of follis, bellows, a ball filled with air, for a stupid person, a jester, a wind-bag), a bufon or jester.

The class of professional fools or jesters, which reached its culminating point of influence and recognized place and function in the social organism during the middle ages, appears to have existed in all times and countries. Not only have there always

1 Per contra, see the article by Mary E. Pennington in the Yearbook for 1907 (1908) of the U.S. Dept. of Agriculture, pp. 107-206, with illustrations of chickens kept in cold storage for two and three years. The results there shown cast considerable doubt on the efficiency of even refrigeration so far as an "indefinite" period is concerned; and it is suggested that the consumption of frozen food may really account for various modern diseases.
been individuals naturally inclined and endowed to amuse others; there has been besides in most communities a definite class, the members of which have used their powers or weaknesses in this direction as a regular means of getting a livelihood. Savage jugglers, medicine-men, and even priests, have certainly been common with the jester by profession. There existed in ancient Greece a distinct class of profession fools whose habits were not essentially different from those of the jesters of the middle ages. Of the behaviour of one of these, named Philip, Xenophon has given a picturesque account in the Banquet. Philip of Macedon is said to have possessed a court fool, and certainly these (as well as court poets and court philosophers, with whom they have some extraordinary common points) were common in a number of the petty courts at that era of civilization, and moriones were the Roman parallels of the medieval witty fool; and during the empire the manufacture of human monstrosities was a regular practice, slaves of this kind being much in request to relieve the languid hours. The jester again has from time immemorial existed at eastern courts. Witty stories are told of Bahalul (see D'Herbelot, s. v.) the jester of Harun al-Rashid, who have long had a place in Western fiction. On the conquest of Mexico court fools and deformed human creatures of all kinds were found at the court of Montezuma. But that monarch no doubt hit upon one great cause of the favor of monarchs for this class when he said that "more instruction was to be gathered from them than from wiser men, for they dared to tell the truth." Douce, in his essay On the Clowns and Fools of Shakespeare, has made a ninefold division of English fools, according to quality and place of employment, as the domestic fool, the city or corporation fool, the tavern fool, the fool of the mysteries and moralities. The last is generally called the "vice," and is the original of the stage clowns so common among the dramatis personae of the time of Elizabeth, and who embody so much of the wit of Shakespeare. A very palpable classification is that which distinguishes between such creatures as were chosen to excite to laughter from some deformity of mind or body, and such as were so chosen for a certain (to all appearance generally very shallow) alertness of mind and power of repartee,—or briefly, butts and wits. The dress of the regular court fool of the middle ages was not altogether a rigid uniform. To judge from the prints and illuminations which are the sources of our knowledge on this matter, it seems to have changed considerably from time to time. The head was shaved, the coat was motley, and the breeches tight, with generally one leg different in colour from the other. The head was covered with a garment resembling a monk's cowl, which fell over the breast and shoulders, and often bore asses' ears, and was crested with a cockcomb, while bells hung from various parts of the attire. The fool's babble was a short staff bearing a ridiculous head, to which was sometimes attached an inflated bladder, by means of which sham castigation were effected. A long petticoat was also occasionally worn, but seems to have belonged rather to the idiots than to the wits.

The fool's business was to amuse his master, to excite him to laughter by sharp contrast, to prevent the over-oppression of state affairs, and, in harmony with a well-known physiological precept, by his liveliness at meals to assist his lord's digestion. The names and the witticisms of many of the official jesters at the courts of Europe have been preserved by popular or state records. In England the list is long between Hiltard, the fool of Edmund Ironside, and Muckle John, the fool of Charles I., and probably the last official royal fool of England. Many are remembered from some connexion with general or literary history. Scogan was attached to Edward IV., and later was published a collection of poor jests ascribed to him, to which Andrew Boorde's name was attached, but without authority.

"Will Sommers, of the time of Henry VIII., seems to have been a kind-hearted as well as a witty man, and occasionally used his influence with the king for good and charitable purposes. Armin, who, in his Nest of Ninnies, gives a full description of Sommers, and introduces many popular fools, says of him—"

"Only this much, he was a poor man's friend, And helpd the widow often in her end. The king, would ever grant what he would crave, For well he knew Will no exacting knave."

The literature of the period immediately succeeding his death is full of allusions to Will Sommers.

Richard Tarleton, famous as a comic actor, cannot be omitted from any list of jesters. A book of Tarleton's Jestis was published in 1614, and, together with his News out of Purgatory, was reprinted by Halliwell Phillips for the Shakespeare Society in 1844. Archie Armstrong, for a too free use of wit and tongue against Lord Lound, had his office and was banished the court. The conduct of the archbishop against the poor fool is not the least item of the evidence which convicts him of a certain narrow-mindedness and pettiness. In French history, too, the figure of the court-jester flits across the gay or sombre scene at times with fantastic effect. Caillotte and Triboulet are well-known characters of the times of Francis I. Triboulet appears in Rabelais's romance, and is the hero of Victor Hugo's Le Roi s'amuse, and, with some changes, of Verdi's opera Rigoletto; while Chicot, the lithe and acute Gusson, who was so close a friend of Henry III., is portrayed with considerable justness by Dumas in his Dame de Monsoreau. In Germany Rudolph of Habsburg had his Pfalz Cappadox, Maximilian I. his Kunz von der Rosen (whose features, as well as those of Will Sommers, have been preserved by the pencil of Holbein), and many a petty court its jester after jester.

Late in the 16th century appeared Le Sottissime Atti di Bertoldo, which is one of the most remarkable books ever written about a jester. It is by Giulio Cesare Croce, a street musician of Bologna, and is a comic romance giving an account of the appearance at the court of Alboin king of the Lombards of a peasant wonderful in ugliness, good sense and wit. The book was for a time the most popular in Italy. A great number of editions and translations appeared, and it was even versified. Though fiction, both the character and the career of Bertoldo are typical of the jester. That the private fool existed as late as the 18th century is proved by Swift's epitaph on Dicky Pearce, the earl of Suffolk's jester.

FOOLS, FEAST OF (Lat. festum stultorum, futilorum, follorum, etc.; fr. g., fool, clown), the name for certain burlesque quasi-religious festivals which during the Middle Ages held a special place in the ecclesiastical counterpart of the secular revelries of the Lord of Misrule. The celebrations are directly traceable to the pagan Saturnalia of ancient Rome, which in spite of the conversion of the Empire to Christianity, and of the denunciation of bishops and ecclesiastical councils, continued to be celebrated by the people on the Kalends of January with all their old licence. The custom, indeed, so far from dying out, was adopted by the barbarian conquerors and spread among the Christian Goths in Spain, Franks in Gaul, Alemani in Germany, and Anglo-Saxons in Britain. So late as the 11th century Bishop Burchard of Worms thought it necessary to fulminate against the excesses connected with it (Decretum, x. c. 5, Migne, Patrologia lat. 140, p. 965).

Then, just as it appears to have been sinking into oblivion among the people, the clergy themselves gave it the character of a special religious festival. Certain days seem early to have been set apart as special festivals for different orders of the clergy: the feast of St Stephen (December 26) for the deacons, St John's day (December 27) for the priests, Holy Innocents' Day for the boys, and for the sub-deacons Circumcision, the Epiphany, or the 11th of January. The Feast of Holy Innocents became a regular festival of children, in which a boy, elected by his fellows of the choir school, functioned solemnly as bishop or archbishop, surrounded by the elder choir-boys as his clergy, while the canons and other clergy took the humbler seats. At first there is no evidence to prove that these celebrations were characterized by any specially indelicate behaviour; but in the 16th century such behaviour had become the rule. In the time of Jean Beleth, of the diocese of Amiens, calls the festival of the sub-deacons festum stultorum (Migne, Patro. lat. 202, p. 79).
The burlesque ritual which characterized the Feast of Fools throughout the middle ages was now at its height. A young sub-deacon was elected bishop, vested in the episcopal insignia (except the mitre) and conducted by his fellows to the sanctuary. A mock mass was begun, during which the lections were read cum farsia, obscene songs were sung and dances performed, cakes and sausages eaten at the altar, and cards and dice played upon it.

This burlesquing of things universally held sacred, though condemned by serious-minded theologians, conveyed to the child-like popular mind of the middle ages no suggestion of contempt, though when belief in the doctrines and rites of the medieval Church was shaken it became a ready instrument in the hands of those who sought to destroy them. Of this kind of retribution Scott in The Abbot gives a vivid picture, the Protestants interrupting the mass celebrated by the trembling remnant of the monks in the ruined abbey church, and insisting on substituting the traditional Feast of Fools.

This naive temper of the middle ages is nowhere more conspicuously displayed than in the Feast of the Ass, which under various forms was celebrated in a large number of churches throughout the West. The ass had been introduced into the ritual of the Church in the 9th century, representing either Balaam’s ass, that which stood with the ox beside the manger at Bethlehem, which carried the Holy Family into Egypt, or that on which Christ rode in triumph into Jerusalem. Often the ass was a mere incident in the Feast of Fools; but sometimes he was the occasion of a special festival, ridiculous enough to mock the Church, but by its means intended in an irreverent spirit. The three most notable celebrations of the Feast of the Ass were at Rouen, Beauvais and Sens. At Rouen the feast was celebrated on Christmas Day, and was intended to represent the times before the coming of Christ. The service opened with a procession of Old Testament characters, prophets, patriarchs and kings, together with heathen prophets, including Virgil, the chief figure being Balaam on his ass. The ass was a hollow wooden effigy, within which a priest capered and uttered prophecies. The procession was followed, inside the church, by a curious combination of ritual office and mystery play, the text of which, according to the Ordo processionis asinorum secundum Rothomagensen usum, is given in Du Cange.

Far more singular was the celebration at Beauvais, which was held on the 14th of January, and represented the flight into Egypt. A richly caparisoned ass, on which was seated the prettiest girl in the town holding in her arms a baby or a large doll, was escorted with much pomp from the cathedral to the church of St Étienne. There the procession was received by the priests, who led the ass and its burden to the sanctuary. Many years later, instead of the ordinary responses to the Introit, Kyrie, Gloria, &c., the congregation chanted “Hinham” (Hee-haw) three times. The rubric of the mass for this feast actually runs: In fine Missae Sacerdos versus ad populum vice, Ite missa est, Hinnabnabil: populus vero vice, Deo Gratias, ter respondit Hinham, Hinham, Hinham (At the close of the mass the priest turning to the people instead of saying, Ite missa est, shall bray thrice: the people, instead of Deo gratias, shall thrice respond Hee-haw, Hee-haw, Hee-haw).

At Sens, the Feast of the Ass was associated with the Feast of Fools, celebrated at Vespers on the Feast of Circumcision. The clergy went in procession to the west door of the church, where two canons received the ass, amid joyous chants, and led it to the precentor’s table. Bizarre vespers followed, sung falsetto and consisting of a medley of extracts from all the vespers of the year. Between the lessons the ass was solemnly fed, and at the conclusion of the service was led by the precentor out into the square before the church (conductus ad ludos); water was poured on the precentor’s head, and the ass became the centre of burlesque ceremonies, dancing and buffoonery being carried on far into the night, while the clergy and the serious-minded retired to matins and bed.

Various efforts were made during the middle ages to abolish the Feast of Fools. Thus in 1108 the chapter of Paris suppressed its more obvious indecencies; in 1270 Pope Innocent III. forbade the feasts of priests, deacons and sub-deacons altogether; and in 1246 Innocent IV. threatened those who disobeyed this prohibition with excommunication. How little effect this had, however, is shown by the fact that in 1265 Odo, archbishop of Sens, could do no more than prohibit the obscene excesses of the feast, without abolishing the feast itself; that in 1444 the university of Paris, at the request of certain bishops, addressed a letter condemning it to all cathedral chapters; and that King Charles VII. found it necessary to order all members in the clergy to forbid it in collegiate churches. The festival was, in fact, too popular to succumb to these efforts, and it survived throughout Europe till the Reformation, and even later in France; for in 1645 Mathurin de Neuré complains in a letter to Pierre Gassendi of the monstrous foolishnesses which yearly on Innocents’ Day took place in the monastery of the Cordeliers at Antwerp.

“Never did pagans,” he writes, “solemnize with such extravagant and obscene ridiculous festivals as do they. . . . The lay-brothers, the cabbage-cutters, those who work in the kitchen occupy the places of the clergy in the church. They don the sacerdotal garments, reverse side out. They hold in their hands books turned upside down, and pretend to read through spectacles in which for glass have been substituted bits of orange-peel.”

See B. Picart, Cérémonies et coutumes religieuses de tous les peuples (1723): du Tillot, Mémoires pour servir à l’histoire de la fête des Fous (Paris, 1749). N. B., there is an earlier edition of this title, 1711, in 4to. — Mathurin de Neuré’s letter is addressed to Pierre Gassendi. He complains of the monstrous foolishnesses which yearly on this day took place in the monastery of the cordeliers at Antwerp. — See also C. F. de la Fosse, Le Carnaval, ou la Fete des Fous, et autres fêtes populaires (1765); G. M. van Wassenhove, Herinneringen uit ’t hertogdom Limburg, ed. 1874; M. N. van Bommel, Onzer feestelijke en geschiedenis (ed. 1877).

FOOLSCAP, the cap, usually of conical shape, with a cockcomb running up the centre of the back, and with bells attached, worn by jesters and fools (see Foot); also a conical cap worn by dukes. The name is given to a size of writing or printing paper, varying in size from 12 x 15 in. to 17 x 15 in. (see Paper). The name is derived from the use of a “fool’s cap” as a watermark. A German example of the watermark dating from 1479 was exhibited in the Caxton Exhibition (1877). The New English Dictionary finds no trustworthy evidence for the introduction of the watermark by a German, Sir John Spielmann, at his papermill at Dartford in 1586, and states that there is no truth in the familiar story that the Rump Parliament substituted a fool’s cap for the royal arms as a watermark on the paper used for the journals of parliament.

FOOL’S PARSLEY, in botany, the popular name for Aethusa cynapium, a member of the family Umbelliferae, and a common weed in cultivated ground. It is an annual herb, with a fleshy root and a smooth hard branched stem 1 to 2 ft. high, with heads of definitely purple and white flowers, and with round umbels of small irregular white flowers. The plant has a nauseous smell, and like other members of the order (e.g. hemlock, water-dropwort), is poisonous.

FOOT, the lower part of the leg, in vertebrate animals consisting of tarsus, metatarsus and phalanges, on which the body rests when in an upright position, standing or moving (see Anatomy: Superficial and Articular; and Skeleton: Appendicular). The word is also applied to such parts of invertebrate animals as serve a foot function or for attachment. “Foot” is a word common in various forms to Indo-European languages, Dutch, voet, Ger. Fuss, Dan. fod, &c. The Aryan root is *ped-,* which appears in Sans. *PAD,* Gr. *pēs,* rōdōs, and Lat. *pes,* pedis. From the resemblance to the foot, in regard to its position, as the base of anything, or as the lowest member of the body, or in regard to its function of movement, the word is applied to the lowest part of a hill or mountain, the plate of a sewing-machine which holds the material in position, to the part of an organ pipe below the mouth, and the like. In printing the bottom of a type is divided by a groove into two portions known as “feet.” Probably referring to the beating of the rhythm with the foot in dancing, the Gr. *pēs,* Lat. *pes* were applied in prosody to a grouping of syllables, one of which is stressed, forming the division of a verse. “Foot,” i.e. foot-soldier, was
FOOT-AND-MOUTH DISEASE—FOOTBALL

1671

formerly, with an ordinal number prefixed, the name of the infantry regiments of the British army. It is now superseded by territorial designations, but it still is used in the four regiments of the infantry of the Household, the Foot Guards. As a linear measure of length the "foot" is of great antiquity, estimated originally by the length of a man's foot (see Weights and Measures). For the ceremonial washing of feet, see Maundy Thursday.

FOOT-AND-MOUTH DISEASE (Aphthous Fever, Epizootic Aphtha, Eczeuma Epizootica), a virulent contagious and indoluble malady of animals, characterized by initial fever, followed by the formation of vesicles or blisters on the tongue, palate and lips, sometimes in the nostrils, fourth stomach and intestine of cattle, and on parts of the body where the skin is thin, as on the udder and teats, between the claws, on the heels, coronet and pastern. The disease begins suddenly and spreads very rapidly. A rise of temperature precedes the vesicular eruption, which is accompanied by salivation and a peculiar "smacking" of the lips. The vesicles gradually enlarge and eventually break, exposing a red raw patch, which is very sensitive. The animal cannot feed so well as usual, suffers much pain and inconvenience, loses condition, and, if a milk-yielding creature, gives less milk, or, if pregnant, may abort. More or less lameness is a constant symptom, and sometimes the feet become very much diseased and the animal is so crippled that it has to be destroyed. It is often fatal to young animals. It is transmitted by the saliva and the discharges from the vesicles, though all the secretions and excretions are doubtless infective, as well as all articles and places soiled by them. This disease can be produced by injecting the saliva, or the lymph of the vesicles, into the blood or the peritoneal cavity.

If we were to judge by the somewhat vague descriptions of different disorders by Greek and Roman writers, this disease has been a European malady for more than 2000 years. But no reliance can be placed on this evidence, and it is not until we reach the 17th and 18th centuries that we find trustworthy proof of its presence, when it was reported as frequently prevailing extensively in Germany, Italy and France. During the 19th century, owing to the vastly extended commercial relations between civilized countries, it has, like the lung-plague, become widely diffused. In the Old World its effects are now experienced from the Caspian Sea to the Atlantic Ocean. Hungary, Lower Austria, Bohemia, Saxony and Prussia were invaded in 1834. Cattle in the Vosges and in Switzerland were attacked in 1837, and the disease extending to France, Belgium and Holland, reached England in 1839, and quickly spread over the three kingdoms (see also under Aphthous Fever). At the same time the invasion of foreign animals into England was prohibited, and it was supposed that the infection must have been introduced by surplus ships' stores, probably sheep, which had not been consumed during the voyage. This invasion was followed at intervals by eleven distinct outbreaks, and since 1902 Great Britain has been free of foot-and-mouth disease. From the observations of the best authorities it would appear to be an altogether exotic malady in the west of Europe, always invading it from the east; at least, this has been the course noted in all the principal invasions. It was introduced into India in 1765, and into the United States of America in 1870, from Canada, where it had been carried by diseased cattle from England. It rapidly extended through cattle traffic from the state first invaded to adjoining states, but was eventually extinguished, and does not now appear to be known in North America. It was twice introduced into Australia in 1872, but was stamped out on each occasion. It appears to be well known in India, Ceylon, Burma and the Straits Settlements. In 1870 it was introduced into the Andaman Islands by the natives from Calcutta, and was then prevalling, and in the same year it appeared in South America. In South Africa it is frequently epizootic, causing great inconvenience, owing to the bullocks used for draught purposes becoming unfit for work. These cattle also spread the contagion. It is not improbable that it also prevails in central Africa, as Schweinfurth alludes to the cattle of the Dinkas suffering from a disease of the kind.

Though not usually a fatal malady, except in very young animals, or when malignant, yet it is a most serious scourge. In one year (1892) in Germany, it attacked 150,929 farms with an estimated loss to the owners of £7,500,000 sterling. It is transmissible to nearly all the domestic animals, but its ravages are most severe among cattle, sheep, goats and swine. Human beings are also liable to infection.

The treatment of affected animals comprises a laxative diet, with salines, and the application of antiseptics and astringents to the sores. The preventive measures recommended are, isolation of the diseased animals, boiling the milk before use, and thorough disinfection of all places and substances which are capable of conveying the infection.

FOOTBALL, a game between two opposing sides played with a large inflated ball, which is propelled either by the feet alone or by both feet and hands. Pastimes of the kind were known to many nations of antiquity, and their existence among savage tribes, such as the Maoris, Faroe Islanders, Philippine Islanders, Polynesians and Eskimos, points to their primitive nature. In Greece the ἀθλητός seems to have borne a resemblance to the modern sport. Of this we read in Smith's Dictionary of Antiquities:— "It was the game at football, played in much the same way as with us, but by a great number of persons divided into two parties opposed to one another." Amongst the Romans the harpastum, derived from the Greek verb ἀπαράστασις, I seize, thus showing that carrying the ball was permissible, bore a certain resemblance. Basil Kennett, in his Roman Antiquae Notitiae, terms this game a "larger kind of ball, which they played with, dividing into two companies and striving to throw it into one another's goals, which was the conquering cast." The harpastum was a gymnastic game and probably played for the most part indoors. The real Roman football was played with the inflated follis, which was kicked from side to side over boundaries, and thus must have closely resembled the modern Association game. Tradition ascribes its introduction in northern Europe to the Roman legion. It has been played in Tuscany under the name of Calcio from the middle ages down to modern times.

Regard the origin of the game in Great Britain the Roman tradition has been generally accepted, although Irish antiquarians assert that a variety of football has been played in Ireland for over 2000 years. In early times the great football festival of the year was Shrovetide Tuesday, though the connexion of the game with this particular date is lost in obscurity. William Fitzstephen, in his History of London (about 1175), speaks of the young men of the city annually going into the fields after dinner to play at the "football" game of ball on the day called dictium Carnicorvium. As far as is known this is the first distinct mention of football in England. It was forbidden by Edward II. (1314) in consequence of the "great noise in the city caused by bustling over large balls (rageries de grosses pelotes)." A clear reference is made "ad pilam...pedinan" in the Rotuli Clausarum, 39 Edward III. (1365), memb. 23, as one of the pastimes to be prohibited on account of the decadence of archery, and the same thing occurs in a Richard II. C. 6 (1388). Both Henry VIII. and James I. prohibited foot-ball, but afterwards, both under the Stuarts and the Georges, seems to have been violent to the point of brutality, a fact often referred to by prominent writers. Thus Sir Thomas Elyot, in his Boke named the Governor (1537), speaks of football as being "nothing but beastly fray and extreme violence, whereas proceedeth hurt and consequently rancour and malice to remayne with thythem that be wounded, wherefore it is to be put in perpetual silence." In Stubbes' Anatomie of Abuses (1585) it is referred to as "a most violent and base pastime...and herof growth envy, hate, malice, and sometimes brawling, murther, homicide, and great effusion of blood, as experience daily teatcheth." Fifty years later (1634) Davenant is quoted (in Hone's Table-Book) as remarking, "I would now make a safe retreat, but methinks I am stopped by one of your heroic games called football; which I conceive (under your favour) not very conveniently civil in the streets, especially in such irregular and narrow roads as Crooked
Lane. Yet it argues your courage, much like your military pastime of throwing at cocks, since you have long allowed these two valiant exercises in the streets."

An evidence of its old popularity in Ireland is that the statutes of Galway in 1527 forbade every other sport save archery, excepting "only the great foot ball." In the time of Charles II. football was popular at Cambridge, particularly at Magdalene College. It is evidenced by the following extract from the register book of that institution under the date 1679—

"That noscholeffer give or receive at any time any treat or collation upon account of ye football play, on or about Michaelmas Day, further than College beere or ale in ye open halle to quench their thirsts. And particularly that that most vile custom of putting up the old housed cloister with spending money—Sophisters and Freshmen together—upon ye account of making or not making a speech at that football time be utterly left off and extinguished."

It never recovered after the most part a game for the masses, and never took root, except in educational institutions, among the upper classes until the 19th century. No clubs or code of rules had been formed, and the sole aim seems to have been to drive the ball through the opposing side's goal by fair means or foul. So rough did the game become that James I. forbade the heir apparent to play it, and describes the exercise in his "Basilikon Doron" as "meeter for laming than making able the users thereof." Both sexes and all ages seem to have taken part in it on Shrove Tuesday; should a hair be put up a house door closed, but there was in the field played in the flagged and walled courts of some schools, as, for example, the old Charterhouse. Hence at such institutions the dribbling style of play, in which Mr Montague Shearman ("Football, in the "Badminton Library") sees the origin of the Association game, came into existence. Only at Rugby (later at some other schools), which from the first possessed an extensive grass field, was the old game preserved and developed, including even its roughness, for actual "hacking" (i.e. intentional kicking of an opponent's legs) was not expressly abolished at Rugby until 1877. The description of the old school game at Rugby contained in Tom Brown's School Days has become classic.

1. Rugby Union.—We have seen that from early times a rudimentary game of football had been a popular form of sport in many parts of Great Britain, and that in the old-established schools football had been a regular game among the boys. In different schools there arose various developments of the original game; or rather, what, at first, must have been a somewhat rough form of horse-play with a ball began to take shape as a definite game, with a definite object and definite rules. Rugby school had developed such a game, and from football played according to the rules of flag game; and the middle of the 19th century that football—up till that time a regular game only among schoolboys—took its place as a regular sport among men. To begin with, men who had played the game as schoolboys formed clubs to enable them to continue playing their favourite school game, and others were induced to join them; while in other cases, clubs were formed by men who had not had the experience of playing the game at school, but who had the energy and the will to follow the example of those who had had this experience. In this way football was established as a regular game, no longer confined to schoolboys. When football was thus first started, the game was little developed or organized. Rules were very few, and often there was great doubt as to what the rules were.

But, almost from the first, clubs were formed to play football according to Rugby rules—that is, according to the rules of the game as played at Rugby school. But even the Rugby rules of that date were few and vague, and indeed almost unintelligible to those who had not been at Rugby school. Still, the fact that play was according to Rugby rules produced a certain uniformity; but it was not till the establishment of the English Union, and the commencement of international matches, that a really definite code of rules was drawn up.

It is an interesting question to ask why it was that the game of Rugby school became so popular in preference to the games of other schools, such as Eton, Winchester or Harrow. It was probably very largely due to the reputation and success of Rugby school under Dr Arnold, and this also led most probably to its adoption by other schools; for in 1860 many schools besides Rugby played football according to Rugby rules. The rapidity with which the game spread after the middle of the 19th century was remarkable. The Blackheath club, the senior club of the London district, was established in 1860, and Richmond, its great rival, shortly afterwards. Before 1870, football clubs had been started in Lancashire and Yorkshire; indeed the Sheffield football club dates back to 1853. Likewise, in the universities of Oxford and Cambridge, Rugby football clubs had been formed before 1870, and by that date the game had been implanted both in Ireland and South Wales; while in Scotland, before 1860, football had taken a hold. Thus by 1870 the game had been established throughout the United Kingdom, and in many districts had been regularly played for a number of years. Rapid as, in some ways, had been the spread of the game between the close of 1860 and 1870, it was nothing compared to what happened in the following twenty years; for by 1890 Rugby football, together with Association football, had become the great winter amusement of the people, and roused universal interest; while to-day on any fine Saturday afternoon in winter there are tens of thousands of people playing football, while those who watch the game can be counted by the hundred thousand. The causes that led to this great increase in the game and interest taken in it were, undoubtedly, the establishment of the various national unions and the international matches; and, of course, the local rivalry of various clubs, together with cup or other competitions prevalent in certain districts, was a leading factor. The establishment of the English Union led to a codification of the rules without which development was impossible.

In the year 1871 the English Rugby Union was founded in London. This Union was an association of some clubs and schools which joined together and appointed a committee and officials to draw up a code of rules of the game. From this beginning the English Rugby Union has become the governing body of Rugby football in England, and has been joined by practically all the clubs in England, and deals with all matters connected with Rugby football, notably the choosing of the international teams. In 1873 the Scottish football Union was founded in Edinburgh on the same lines, and with the same objects, while in 1880 the Welsh Football Union, and in 1881 the Irish Rugby Football Union, were established as the national unions of Wales and Ireland, though in both countries there had been previously Unions not thoroughly representative of the country. All these Unions became the chief governing body within their own country, and one of their functions was to make the rules and regulations by which the game was played, and, further, to arrange matches; and, as a result of the English Union, the others adopted the English rules, with amendments to them from time to time. This state of affairs had one element of weakness viz. that since all the Unions made their own rules, if ever a dispute should arise between any of them, a dead-lock was almost certain to ensue. Such a dispute did occur in 1884 between the English and Scottish Unions. This dispute eventually turned on the question of the right of the English Union to make and interpret the rules of the game, and to be the paramount authority in the game, and superior to the other Unions. Scotland, Ireland and Wales resisted this claim, and finally, in 1885, Lord Kinnear, and Major Marindin were appointed as a commission to settle the dispute. The result was the establishment of the International Board, which consists of representatives from each Union—six from England, two from each of the others—whose duties were to settle any
question that might arise between the different Unions, and to settle the rules under which international matches were to be played, these rules being invariably adopted by the various Unions as the rules of the game.

With the establishment of the International Board the organization of the game was complete. Still harmony did not prevail, and in 1895 occurred a definite disruption. A number of leading clubs in Yorkshire and Lancashire broke off from the English Union and formed the Northern Union, which since that date has had many successes, and has become the leading body in the north of England. The question in dispute was the payment of players. Football was originally played by men for the sheer love of the game, and by men who were comparatively well-to-do, and who could give the time to play it; but with the increasing popularity of the game it became the pastime of all classes of the people, and clubs began to grow rich by "drawing big gates."—that is, large numbers of spectators, frequently many thousands in number, paid for the privilege of witnessing the match. In these circumstances the temptation arose to reimburse the player for any out-of-pocket expenses he might be put to for playing the game, and thus it became universally recognized as legitimate to pay a player wages and expenses to and from a match. But in the case of working men it often meant that they lost part of their weekly wage when they had to go a distance to play a match, or to go on tour with their club—that is, go off for a few days and play one or two matches in different parts of the country—and consequently the claim was made on their behalf to recoup them for their loss of wage; while at the same time rich clubs began to be willing to offer inducements to good players to join their club, and these inducements were generally most acceptable in the form of money. In Association football (see below) professionalism—i.e. the hiring and paying of a player for his services—had been openly recognized. A large section of the English Union—the amateur party—would not tolerate anything that savoured of professionalism, and regarded payments made to a player for broken time as illegitimate. The result was the formation of the Northern Union, which allowed such payments, and has practically recognized professionalism. This body has also somewhat altered the laws of the game, and reduced the number of players constituting a team from fifteen to thirteen. In Scotland and Ireland Rugby footballers are strongly amateur; but in England Rugby football is the popular game of the artisan, and the professional element is strong.

Besides legislation, one of the functions of the Unions is to select international teams. On the 27th of March 1871 the first international match was played between England and Scotland in Edinburgh. This was a match between teams picked from English and Scottish players. These matches from the first roused widespread interest, and were a great stimulus to the development of the game. With the exception of a few years, when there were disputes between their respective Unions, all the countries of the United Kingdom have annually played one another—England having played Scotland since 1871, Ireland since 1875 and Wales since 1886. Scotland commenced playing Ireland in 1877 and Wales in 1883, while Ireland and Wales met first in 1882 and then in 1884, and since 1887 have played annually. The qualifications of a player for any country were at first vaguely considered to be birth; but they were never definitely settled, and there has been a case of a player playing for two countries. In 1894, however, the International Board decided that no player was to play for more than one country, and this has been the only pronouncement on the question; and though birth is still looked upon as the main qualification, it is not essential. Though international matches excite interest throughout the United Kingdom, the matches between two rival clubs arouse just as much excitement in their district, particularly when the clubs may be taken as representatives of two neighbouring rival towns. But when to this rivalry there is added the inducement to play for a cup or prize, the excitement is much more intense. Among Rugby footballers cup competitions have never been so popular as among Association, but the competition for the Yorkshire Cup was very keen in the days before the establishment of the Northern Union, and this undoubtedly was the main cause of the popularity of the game in that county. Similarly the competition for the South Wales Cup from 1875 to 1880 did a great deal to establish the game in that country. The method of carrying on these competitions is that all clubs entered are drawn by lot, in pairs, to play together in the first round; the winners of these ties are then similarly drawn in pairs for the next round, until for the final round there is only one pair left, the winner of which takes the cup. An elaboration of this competition is the "League system" of the Association game. This, likewise, has not been popular with Rugby players. Still it exists in some districts, especially where clubs are anxious to draw big gates. In the League system a certain number of clubs form a league to play one another twice in each season; two points are counted for a win and one for a draw. The club which at the end of the season comes out with most points wins the competition. The advantage of this system over a cup competition is, that interest is kept up during the whole season, and one defeat does not debar a club from eventually coming out first.

It is said that wherever Britons go they take their games with them, and this has certainly been the case with Rugby football, especially in New Zealand, South Africa and Australia. An interchange of football matches between these colonies and the motherland is now an important feature in the game. These tours date from 1888, when an English team visited Australia and New Zealand. In the following season, 1889, a team of New Zealanders, some of whom were native Maoris, came over to England, and by their play even then indicated how well the grammar of the game had been studied in that colony. Subsequently several British teams visited at intervals New Zealand and Australia, and in 1905 New Zealand sent home a team which eclipsed anything previously accomplished. They played altogether thirty-three matches, including fixtures with England, Ireland, Scotland and Wales, and only sustained one defeat, viz. by a try in their match with Wales, a record which speaks for itself. In 1908 a combined team of English and Welsh players toured in New Zealand and Australia, and also visited Canada on their way home. The team was not so strong as could have been wished, and though they did fairly well in Australia, they lost all three "test matches" against New Zealand. In South Africa the game is followed with equal enthusiasm, and the play is hardly inferior, if at all, to that of the New Zealanders. The first British team to visit the Cape went in 1891 through the generosity of Cecil Rhodes, who guaranteed the undertaking against loss. Teams were also sent out in 1896 and 1903; the result of matches played in each visit showing the steady improvement of the colonists. In 1906 the South Africans paid their first visit to England, and the result of their tour proved them to be equally formidable with the New Zealanders. England managed to draw with them, but Scotland was the only one of the home Unions to gain a victory. The success of these colonial visits, more especially financially, created a development very foreign to the intentions of their organizers. The Northern Union as a professional body had drifted into a somewhat parlous state, through suffering on the one hand from a lack of international matches, and on the other from the competition of Association professional teams. The great financial success resulting from the New Zealand tour of 1905 roused the attention of the Northern Union authorities, and they quickly entered into negotiations with New Zealand players to collect a team who would come over and play the Northern Union clubs, the visiting players themselves taking a share of the gate-money. For this purpose a team of New Zealanders toured the north of England in 1907, and their action caused the introduction of professional or Northern Union football in both New Zealand and Australia.

The spread of the game has not, however, been confined to English-speaking lands. In France it has found fruitful soil, and numerous clubs exist in that country. Since 1906 international matches have been played between France and England, and the energy of French players, coupled with their national...
FOOTBALL

The game itself is essentially a winter pastime, as two requisite conditions for its enjoyment are a cool atmosphere and a soft though firm turf. The field of play is an oblong, not more than 110 yds. long nor more than 75 yds. broad, and it usually approximates to these dimensions. The boundaries are marked by lines, called touch-lines, down the sides, and goal-lines along the ends. The touch-lines are continued beyond the goal-lines for a distance of not more than 25 yds.; and parallel to the goal-line and behind it, at a distance of not more than 25 yds., is drawn a line called the dead-ball line, joining the ends of the touch-lines produced. On each goal-line, at an equal distance from the touch-lines, are erected two posts, termed goal-posts, exceeding 17 ft. in height, and generally much more—averaging perhaps from 20 to 30 ft. from the ground, and placed 18 ft. 6 in. apart. At a height of 10 ft. from the ground they are joined by a cross-bar, and the object of the game is to kick the ball over the cross-bar between the upright posts, and so obtain a goal. The ball is egg-shaped (strictly an oblate spheroid), and the official dimensions are—length, 11 to 11½ in.; length circumference, 30 to 31 in.; width circumference, 25½ to 26 in.; weight, 13 to 14½ oz. It is made of indiarubber inflated, and covered with a leather case. Halfway between the two goal-lines there is generally drawn the half-way line, but sometimes it is marked by flags on the touch-line; and 25 yds. from each goal-line there is similarly marked the 25-yds. line. In the original game the side that had gained the majority of goals won the match, and it is the rule of the game, and a fundamental principle, that no kicking, no matter how long or short, may ever be done by the hands, and said to be left drawn; but a modification was adopted before long. A goal can be kicked from the field in the ordinary course of play; but from the very first a try goal could be obtained by that side one of whose players either carried the ball across his opponents’ goal-line and then touched it down (i.e. on the ground), or touched it down after it had been kicked across the goal-line, before any of his opponents. The “try” is then proceeded with as follows: the ball is taken out by a member of the side obtaining the try in a straight line from the spot where it was “touched down,” and is deposited in a selected position on the ground in the field of play, the defender being all confined behind their own goal-line until the moment the ball is so placed on the ground, when another member of the attacking side endeavours to kick it from the ground (a “place kick”) over the bar and between the goal-posts. Frequently a goal is kicked; very often not. The modification first allowed was to count side the winner which had gained the majority of tries, provided no goal or an equal number of goals had been scored; but a majority of one goal took precedence of any number of tries. But this, too, was afterwards abolished, and a system of points instituted by which the side with the majority of points wins. The numerical value, however, of goals and tries has undergone several changes, the system in 1908 being as follows:—A try counts 3 points. A goal from a try (in which case the try shall not count) 5 points. A dropped goal (except from a mark or a penalty kick) 4 points; a dropped goal being a goal obtained by a player who drops the ball from his hands and kicks it the moment it rises off the ground, as in the “half-volley” at cricket or tennis. A goal from a mark or penalty kick 3 points. Under the Northern Union code any sort of goal counts 2 points, a try counts 3; but if a try be converted into a goal, both try and goal count, i.e. 5 points are scored.

In the game itself not only may the ball be kicked in the direction of the opponents’ goal, but it may also be carried; but it must not be thrown forward or knocked on—that is, in the direction of the opponents’ goal—though it may be thrown back. Thus the game is really a combination of football and handball. The main principle is that any one who is not “offside” is in play. A player is offside if he gets in front of the ball—that is, on the opponents’ side of the ball, nearer than a colleague in possession of the ball to the opponents’ goal-line; when in this position he must not interfere with an opponent or touch the ball under penalty. The leading feature of the game is the “scrummage.” In old days at Rugby school there was practically no limit to the numbers of players on each side, and not infrequently there would be a hundred or more players on one side. This was never prevalent in club football; twenty a-side was the usual number to start with, reduced in 1877 to fifteen a-side, the number still maintained. In the old Rugby big sides the ball got settled amidst a mass of players, and each side attempted to drive it through this mass by shoving, kicking, and otherwise forcing their way through with the ball in front of them. This was the origin of the scrimmage.

The game is played usually for one hour, or one hour and ten minutes, sometimes for one hour and a half. Each side defends each goal in turn for half the time of play. Of the fifteen players who compose a side, the usual arrangement is that eight are called “forwards,” and form the scrummage; two “half-backs” are posted outside the scrummage; and four “three-quarter-backs,” a little behind the halves, stretch in a line across the field, their duties being mainly to run and kick and pass the ball to other players on their own side, and to prevent their opponents doing the same. In recent years, owing to the development of “passing,” the field position of the half-backs has undergone a change. One stands fairly close to the scrummage and is known as the “scrum-half,” the other takes a position between the latter and the three-quarters, and is termed the “stand-off.” Behind the three-quarters comes the “full-back” or “back,” a single individual to maintain the last line of defence; his duties are entirely defensive, either to “tackle” an opponent who has managed to get through, or, more usually, to catch the ball when it is kicked by one of the three-quarters, or after it has been put off from the centre of the field in the direction of the opponents’ goal. The ball is then caught by one of the other side, who either kicks it or runs with it. In running he goes on until he is “tackled,” or caught, by one of his opponents, unless he should choose to “pass” or throw it to another of his own side, who, provided he be not offside, may either kick, or run, or pass as he chooses. The ball in this way is kept moving until it crosses the touch-line, or goal-line, or is tackled. If the ball crosses the touch-line both sides line up at right angles to the point where it crossed the line, and the ball is thrown in between the players of the attacking side, and the ball is then put into play in touch with the touch-line, or, if the ball was kicked or thrown out, by one of the opposite side. If the ball crosses the goal-line either a try is gained, as explained above, or if the defending side touch it down first, the other side retire to the line 25 yds. from the goal-line, and the defending side kick it up the field. If the ball is tackled the player carrying the ball gets up from the ground as soon as possible, and the forwards at once form the scrummage by putting down their heads and getting ready to shove against one another. They show as soon as the ball is put down between the two front rows. In the scrummage the object is, by shoving the opponents back or otherwise breaking away with the ball in front, to carry the ball in the direction of the opponents’ goal-line by a series of short kicks in which the players run after the ball as fast as possible, while their opponents lie in wait to get the ball, and either by a kick or other device stop the rush. Instead, however, of the forwards breaking away with the ball, sometimes they let the ball come out of the scrummage to their half-backs, who either kick or run with it, or pass it to the three-quarter-backs, and so the game proceeds until the ball is out of the “dead-ball” zone, brought in on a standstill. The scrummage appears to be an uninteresting manoeuvre, and a strange relic of bygone times; but it is not merely a manoeuvre in which weight and strength alone tell—it also needs a lot of dexterity in moving the ball with the feet, applying the weight to best advantage, and also in outflanking the opposing side, as it were—usually termed wheeling—directing all the force to one side of the scrummage and thus breaking away. As a rule the game is a lively one, for the players are rarely at rest; if there is much scrummaging it is called a slow game, but, if much running and passing, a fast or an open game. The spectator, unless he be an expert, prefers the open
FOOTBALL

There is generally supposed that the English game of Association football is the outcome of the game of football as played at Cambridge University about the game of the eighteenth century. In October 1863 a committee, consisting of representatives of the schools of Eton, Harrow, Rugby, Marlborough, Shrewsbury and Westminster, drew up a code of laws which settled the fundamental principle of the "Association" game as distinct from the various forms of the game which permitted of handling and carrying the ball. In a rule, football is the use of the hands or arms, either for the purposes of playing the ball or impeding or holding an opponent, is absolutely prohibited; "dribbling" or kicking the ball with the feet, and propelling it by the head or body, are the methods to be adopted. The Cambridge laws specially provided for "kicking" the ball. Laws 13 and 14 provided that, "the ball, when in play, may be stopped by any part of the body, but may not be held or hit by the hands, arms or shoulders. All charging is fair, but holding, palming, and impeding hands or shoulders tripping, and impeding the passage of the ball, is prohibited.

The laws of Association football first took practical shape as the result of a meeting held on the 26th of October 1863 at the Freemasons' Tavern, London. The clubs which sent delegates were representative of all classes of football then played. The meeting was a momentous one, for not only was the foundation laid of the Football Association, the national association which has since then controlled the game in England, but as the outcome of the differences in opinion which existed as to "kicking," being permissible under the laws, the representatives who favoured the inclusion of the practice, which is now so roundly condemned in both the Association and Rugby games, withdrew and formed the Rugby Union.

The Cambridge laws were considered by the committee of the Football Association at their meeting on the 24th of November 1863. They took the view that those laws "embraced the true principles of the game with the greatest simplicity"; the laws were "officially" passed on the 1st of December 1863, and the first publication was made in Bell's Life four days later. These laws have from time to time been modified, but the principles as laid down in 1863 have been adhered to, and the Association game itself has altered very little since 1880. The usual dimensions for a ground are 120 yards long by 80 yards wide, and the goals are 8 yards in width with a cross-bar from post to post 8 ft. from the ground. The ball is about 14 oz. in weight, and must be a perfect sphere from 27 to 28 in. in circumference, as distinguished from the elliptical or egg-shaped Rugby ball. A rectangular space extending to 18 yds. in front of the goals, and marked with lines on the ground, constitutes the "penalty area," within which, at a distance of 12 yds. opposite the centre of the goal, is the "penalty kick mark." The boundary lines at the sides of the field are called the "touch-lines"; those at the ends (in the centre of which are the goals) being the "goal-lines." The game is started by a place kick from the centre of the field of play, and none of the opposite side is allowed to approach within 10 yds. of the ball when it is kicked off. When the ball passes over the touch line it has to be thrown in by one of the opposite side, and can be returned into the field of play in any direction. If it passes over the goal-line at any time without touching one of the defending side, it has to be kicked out by the goalkeeper or one of the backs from a line marked in front of goal, the spot selected being in front of the post nearest the point where the ball left the field of play. But should it touch one of the defending side in its transit over the goal-line the attacking side has the privilege of a free kick from the corner flag (a "corner kick"). This is often a great advantage, but such free kick does not produce a goal unless the ball touches one of the other players on its way to the post. Ordinarily a free kick is scored when the ball goes between the goal-posts and under the cross-bar, not being thrown, knocked on or carried. The regulation duration of a game is an hour and a half, and ends are changed at forty-five minutes. The side winning the toss has the choice of ends or kick-off, and the one obtaining the majority of goals wins. A goal cannot be scored from a free kick except when the free kick has been awarded by the referee as a penalty for certain infringements of the rules by the opposite side, and if such infringement take place within the penalty area on the part of a player on the side then defending the goal, and in the judgment of the referee be intentional, a "penalty kick" is awarded to the attacking side. The penalty kick is a free kick from the penalty kick mark, all the players of the defending side being excluded from the penalty area except the goalkeeper, who is confined to the goal-line; the result, therefore, may be such that a certain goal cannot be scored.

A player is always in play as long as there are three of the opposite side between him and the opposite goal at the time the ball is kicked. This "offside" rule gives much trouble to the young player, though why it should do so it is not easy to say. The rule is simple if the words in italics are remembered. The ball must not be carried, knocked or wilfully handled under any pretence whatever, save by the goalkeeper, who is allowed to use his hands in defence of his goal, either by knocking on or throwing, within his own half of the field of play. Thus far he is entitled to go in maintaining his goal, but if he carry the ball beyond the goal line, the penalty is a free kick. There are other infringements of the rules which also involve the penalty of a free kick, among them the serious offences of tripping, hindering and jumping at a player. Players are not allowed to wear nails in their boots (except such as have their heels driven in flush with the leather), or metal plates or gutta-percha, and any player discovered infringing this rule is liable to be prohibited from taking further part in a match.

In the early 'sixties of the nineteenth century there were probably not more than twenty-five organized clubs playing Association football in the United Kingdom, and these were chiefly confined in the south of England to the universities and public schools. But whilst the game was being established in the south it was making steady progress in the north, particularly in Yorkshire, where the Sheffield Club had been formed as early as 1854. In 1857 the game had become so well established that it was decided to play an inter-county match. The match, which was played "in the wilds of Battersea Park," terminated in a draw, neither side having obtained a goal, and it did much to stimulate the growing popularity of the game. During the season 1870-1871, only three years later, two matches of an international character were played between Englishmen and Scotsmen in membership with the Football Association; they were not, however, recognized as "international" matches. The first real international match, England v. Scotland, was played on the 30th of November 1872 at Partick, Glasgow; the first international match between England and Wales was played at Kennington Oval in 1879, and that between England and Ireland at Belfast in 1882. In 1896 amateur international matches were inaugurated with Germany, Austria and Bohemia; and games are now annually played with Scotland, Wales, Ireland, France, Belgium, Germany, Holland, Austria and other continental countries. As the outcome of the international relations with Scotland, Wales and Ireland, an International Football Association Board was formed in 1882, when a universal code of laws was agreed upon. Two representatives from each of the four national associations constitute the board, whose laws are accepted and observed not only by the clubs and players of the United Kingdom but in all countries where the Association game is played. At a meeting held at Paris on the 21st of May 1904 the "International Federation of Association Football" was instituted. It consists of the recognized national associations in the respective countries, and its objects are to develop and control Association international football. The countries in federation are: Austria, Belgium, Denmark, England, Finland, France, Germany, Hungary, Italy, Norway, Sweden and Switzerland.

The small number of clubs taking part in the game in the early days becomes of interest when compared with the magnitude of
the game in the 20th century. Association football has become one of the most popular of all national sports in the United Kingdom. It is slowly but surely taking a similar position on the continent of Europe and is making progress even in the Far East, Japan being one of its latest adherents. In the season of 1871-
1872 the Football Association inaugurated its popular challenge

cup competition which is now competed for by both amateur and

professional clubs. In the first year fifteen clubs entered, all of

which were from the south of England. The first winners of the

cup were the Wanderers, who defeated the Royal Engineers in the

final tie by one goal to nothing. For the first ten years the

competition was mostly limited to the southern clubs, but in the

season of 1881-1882 the Blackburn Rovers were only defeated in the

final tie by the Old Etonians by one goal to nothing. Professional

footballism was then unknown in the game, and comparatively

little interest was taken in it except by the players themselves.

In the following season of 1882-1883 the cup was for the first time

taken north by the Blackburn Olympic Club, and it remained in

the north for the next nineteen years, until in the season of 1900-

1901 it was again brought south by the Tottenham Hotspur Club, who

defeated the Sheffield United Club at Bolton by three goals to one. In

the following season the cup was again taken north by the Bury Club.

In the early days of the competition a few hundred people only attended the final tie, while the average attendance by

the clubs was very small. The membership of the clubs, of course,

increased slowly but steadily, and by 1890 the number of clubs was

356 entered, in 1908-1909 3356 clubs entered the competition; in 1910-11 the number had increased to 404.

The great development of the game necessitated many changes

in the system of control. About the year 1880 (although contrary to

the rules) a practice of making payment to players crept into

the game in the north of England and slowly developed. After

some years of debate as to the best method of dealing with this

development the Football Association decided in 1885 to legalize

and control the payment of players. The rules define a profes-

sional player as one who receives remuneration of any sort

above his necessary hotel and travelling expenses actually paid, or

is registered as a professional. They further provide that training

expenses not paid by the players themselves will be considered as

remuneration beyond necessary travelling and hotel expenses.

Players competing for any money prizes in football contests are

also considered professionals.

In 1888 the Football League, a combination of professional

cubs of the north and midlands of England, was formed; and a

new scheme was inaugurated for the playing of matches on what is

known as the "League" principle, the essential advantage of which is

that the clubs in membership of a league agree to play with each other "home and home" matches each season, and also

bind themselves under certain penalties to play their best

team in all league matches. Six years later the Southern League

came into existence, primarily with the object of increasing the

interest in the game in the south and west of England. The

Football League and the Southern League very soon had their

imitators, and in 1909 there were upwards of six hundred league

competitions playing under the sanction and control of the Foot-

ball Association. In 1882 the Football Association considered the

principle of a split流行 being introduced; in 1886 the South

Wales and Ireland, and has extended to most of the colonies

where Association football is played. In the season of 1893-1894

the Amateur Cup Competition, restricted to amateur clubs in

membership with the Football Association, was inaugurated.

In the first season 32 clubs entered, and the growing popularity

of the competition is shown by the fact that in the season of 1908-

1909 there were 235 entries.

The Football Association, founded in 1863 with its eleven clubs,
FOOTBALL

The literature of British football is very extensive, but the following works are among the best: Football in the "Bateman's Library" (London, 1904), where the different games played at Eton, Harrow, Rugby, Winchester and other public schools are thoroughly described; F. Marshall, Football; the Rugby Game (London, Cassells); J. E. Vincent, Football; its History for Five Centuries (London, 1885); C. J. B. Marriott and C. W. Meeock, Football ("Oval Series"); "Football," in the Encyclopedia of Sport; The Rugby Football Union Handbook; Richardson, Greenwich, Official Annual; and The Football Annual, Merritt and Hatcher (Association Game), London.

United States.—In America the game of football has been elaborated far more than elsewhere, and involves more complications than in England. From colonial times until 1871 a kind of football generally resembling the English Association game was played on the village greens and by the students of colleges and academies. There was no running with the ball, but dribbling, called "laboring," was common. In 1871 a code of rules was drawn up, but they were unsatisfactory and not invariably observed. "Batting the ball," i.e. striking the ball forward with the fists, was allowed. There were two backs, sixteen ruggers or forwards, and two very "peanuts," who lurked near the opponents' goal. During this period the first international football game was played at Yale between the college team and one made up of old Etonians, the rules being a compromise between the American and the English.

English Rugby, introduced from Canada, was first played at Harvard University, and in 1875 a match under a compromise set of rules, taken partly from the Rugby Union and partly from the existing American game, was played with Yale. The following year Yale adopted the regular Rugby Union rules, and played Harvard under these. Later, several other colleges adopted these English rules. Absence of tradition necessitated expansion of these laws, and a convention of colleges was assembled. Henceforward annual conventions were held, which from time to time altered and amplified the rules. A college association was formed, and the game grew in popularity. Public criticism of the roughness shown in the play early threatened its existence; indeed at one time the university authorities compelled Harvard to abstain from the annual game with Yale. Changes in the rules were introduced, and the game has been characterized by less roughness and by increased skill. It has become the most popular autumn game in the United States, the principal university matches often attracting crowds of 25,000 and even 40,000 spectators. The association subsequently disbanded, but a Rules Committee, invited by the University Athletic Club of New York, made the necessary changes in the rules from time to time, and these have been accepted by the country at large. In the West associations were formed; but the game in the East is played principally under separate agreements between the contesting universities, all using, however, one code of rules. Later this Rules Committee amalgamated with a new committee of wider representation. Amateur athletic clubs as well as public and private schools have also taken up the game. The American football season lasts from the middle of September to the first of December only, owing to the severity of the American winter. Professional football is not played in America.

The American Rugby game is played by teams of eleven men on a field of 330 ft. long and 160 ft. wide, divided by chalk lines into squares with sides 5 yds. long, leaving a strip 5 ft. wide on each side of the field. Until 1903 the field was divided by latitudinal lines only and was therefore popularly called the "gridiron"; subsequently it was called the "checkerboard." The end lines are called "goal-lines," the side "touch-lines." The two lines 25 yds. from each goal-line, and the middle line, or 55 yard-line, are made broader than the rest. In the middle of each goal-line is a goal, consisting of two uprights exceeding 20 ft. in length, set 18 ft. 6 in. apart with a crossbar 10 ft. from the ground. The ball is in shape and material of the English Rugby type. A match game consists of two periods (halves) of thirty-five minutes with an interval of fifteen minutes. Practice games usually have shorter halves. There are four officials: the umpire, whose duty it is to watch the conduct of the players and decide regarding fouls; the referee, who decides questions regarding the progress of the ball and of play; the field judge who assists the referee and keeps the time; and the linesman, who (with two assistants, one representing each half) marks the distance gained or lost in each play.

In scoring, a "touchdown" (the English Rugby "try") counts 5 points, a goal from a touchdown 6 (or one added to the 5 for the touchdown), a "goal from the field," whether from placement or drop-kick, 4, and a "safety" (the English Rugby " touchdown") 2. Mutatis mutandis, these are made as in English Rugby. American Rugby differs from the English game, because in the scrimmage the men are lined up opposite each other, and, although separated by the length of the ball, are engaged in a constant man-to-man contest, and also in that a system of "interference" is allowed. Furthermore, a player in the American game is put "on side" when a kicked ball strikes the ground; and forward passing, i.e. throwing the ball toward the opponents' goal, is permissible under certain restrictions. The costume usually consists of a close-fitting jersey with shoulders and elbows padded and reinforced with leather; short trousers with padded thighs and knees, heavy stockings and shoes with leather cleats. In the early period of the game caps were worn, but, as they were impossible to keep on, they were discarded in favour of the wearing of long hair, and the "chrysanthemeum head" became the distinguishing mark of the football player. This, however,
proven an inadequate protection, and some players now wear a
"head harness" of soft padded leather. Substitutes are allowed in
the places of injured players.

The object of the game is identical with that of English Rugby,
and the rules in regard to fair catches, punting, drop-kicking,
place-kicking, goal-kicking, passing and gentlemanly conduct are
practically the same except that, in order to get a free kick after a fair
catch, the opposing players in the American game may not come
up to the mark but must keep 10 yds. in front of it. In the
American game there is no scrummage in the English sense, nor
is the ball thrown in at right angles after going into touch. The
element of chance in both these methods of play was done away
with by the enunciation of the principle of the "possession of the
ball." In America, when the ball has gone out of bounds or a
runner has been tackled and held and the ball downed, the ball is
also put into play by an evolution called a scrummage, usually
called "line-up," which by the name bears no resemblance to
the English scrummage. The ball, at every moment of the
game, belongs theoretically either to one side or to the other.
It may be lost by a fumble, or by the side in possession not being
able to make the required distance of 10 yds. in three successive
attempts or by a voluntary kick. In the line-up the seven line-
men (i.e. forwards) face each other on a line parallel to the
goal-line on the spot where it was ordered down by the referee.
The ball is placed on the ground by the centre-rush, also called the
snapper-back, who, upon the signal being given by his quarter-
back, he places the ball on the goal-line and tosses it up to him
by a quick movement of the hand or foot. The moment the ball is
snapped-back it is in play. In every scrummage it is a foul for the
side having the ball (attacking side) to obstruct an opponent
except with the body (no use may be made of hands or arms);
or for the defending side to interfere with the snapshot. The
defenders may use their hands and arms only to get their
opponents out of the way in order to get at the man with the ball.
Each member of the attacking side endeavours, of course,
to prevent his opponents from breaking through and interfering
with the quarter-back, who requires this protection from his line
in order to have time to pass the ball to one of the backs, whom he
has notified by a signal to be ready. In the United States a
player may be obstructed by an off-side opponent so long as hands
and arms are not used. In the line-up (this is called "blocking-off")
and "interference" when done to protect a friend running with
the ball. Interference is one of the most important features
of American football. As soon as the ball is passed to one of
the half-backs for a run, for example, round one end of the line, his
interference must immediately cease. This means that one or
more of his fellows must accompany and shield him as he runs,
but that is impossible, in order to prevent the man who catches
the kick-off from running back with the ball. When the kick-off
is caught, the catcher with the aid of interference runs it back
as far as possible, and as soon as he is tackled and held by his
opponents the ball is down and a line-up takes place, the ball
being in the possession of the catcher's side, which now attacks.
In order to prevent the so-called "block game," once prevalent,
in which neither side made any appreciable progress, the rules
provide that the side in possession of the ball must make at
least 10 yds. in three successive attempts, or, failing to do so,
must surrender the ball to the enemy, or, as it is called, "lose
the ball on downs." This is infrequent in actual play, because
if, after two unsuccessful attempts, or partly successful, it becomes
evident that the chances of completing the obligatory 10-yaad
pass or a kick is resorted to, rather than risk losing the ball on
the spot. The kick, although resulting in the loss of the ball,
nevertheless gives it to the enemy much nearer his goal. When
the wind is strong the side favoured by it usually kicks often,
as the other side, not being able to kick back on equal terms,
is forced to play a rushing game, which is always exhausting.
Again, the kicking game is often resorted to by the side that has
the lead in the score, in advance in the time, as well as retaining
the advantage. The only remaining way to advance the ball is on
a free-kick after a fair catch, as in the English game. The free
kick may be either a punt, a drop-kick or a kick from placement.
Whenever the ball goes over the side line into touch it is brought
back to the point where it crossed the line by the man who
carried it over, or, if kicked or knocked over, by a man of the
side which did not kick it out, and there put in play in one of
two ways. Either it may be touched to the ground and then
kicked at least 10 yds. away, or, if it is 5 yds. or more
from the line, it may be taken into the field at right angles to the line a distance
not less than 5 yds. nor more than 15, and there put down for a
line-up, the player who takes it in first declaring how far he will
go, so that the opposing team may not be caught napping.

Of the seven men in the line, the centre is chosen for his
weight and ability to handle the ball cleanly in snapping back.
He must also, in case the full-back is to make the next play,
be able to throw the ball from between his legs accurately into
the full-back's hands, thus saving the time that would be wasted
if the quarter-back were used as an intermediary. The two
backs who make this position for him. As soon as he side obtains
the bulk of the line, protecting the backs in offence, and in
defence blocking the enemy. The two "tackles" must be heavy
yet active and aggressive men, as they must not only help the
centre and guards in repelling assaults on the middle of the line,
but also assist the ends in stopping runs round the line as well
as those between tackle and end, a favourite point of attack.
The "ends" are chosen for their activity, sure tackling, fast
running and ability to follow up the ball after a kick. Of
the four players behind the line, the full-back must be a sure
catcher and tackler and a fast runner. The two half-backs
must also be fast runners and good dodgers. One of them is
often chosen for his ability to gain ground by "bucking the line," i.e. plunging through the opposing team's line. He must therefore
be over the average weight, while the other half-back is called
upon to gain by running round the opposing ends. The quarter-
back is the commanding general and therefore the most important
member of his side, as with him lies the choice of plays to be
made when on the attack. Courage, coolness, promptness in
decision and discrimination in the choice of plays are the qualities
he is required to possess. When the man in charge of the
ball, the quarter-back shouts out a signal, consisting of a
series of numbers or letters, or both, which denotes a certain
play that is to be carried through the moment the ball is snapped
back. A good quarter-back thinks rapidly and shouts his signal
for the next play as soon as a down has been called and while
the scrummage is forming, so that the plays are run off rapidly
and the enemy is given as little time as possible to concentrate.
The signals, which are secret and often changed to guard them
from being solved by the enemy, are formed by designating
every position in the line, and each other player, or each other
open play, by a number or letter. Some signals are called
sequence-signals, and indicate a prearranged series of plays for
use in certain emergencies. Every manoeuvre of the attacking
side is carried out by every member of the team, the ideal being
"every man in every play every time." As soon as a signal is
given each man should know what part of the ensuing move will
fall to him, in carrying the ball, interfering for the runner, or
getting down the field under a punt. Every team has its own code.
About 1890 the system of interference led to momentum
and mass plays (wedging-formations, tandems, &c.), i.e. to the grouping
of blocks of men behind the line, and starting them before
the ball was snapped back, so that they struck the line with an
acquired momentum that was extremely severe, particularly
when met by men equally determined. These plays caused
FOOTE, A. H.—FOOTE, SAMUEL

frequent injuries and led to legislation against them, the most important law providing for a limitation to the number of men who could be dropped back of the line, and practically keeping seven men drawn up in the line.

Penalties are of three kinds: (1) forfeiture of the game, for refusing to play when directed to do so by the referee, and for repeated fouls made with the intention of delaying the game; (2) disqualification of players for unnecessary roughness or ungentlemanship conduct; and (3) for infringement of rules, for which certain distances are taken away from the previous gains of the side making the fouls.

The game resolves itself into a series of scrimmages interspersed with runs and kicks. The systematized development of plays places at the disposal of the quarter an infinite variety of attack, which he seeks to direct at the opposing line with bewildering rapidity and dash. During the preliminary games of the season "straight football" is generally played; that is, intricate attacks are avoided and kicks and simple plunges into the line are mainly relied upon. "Trick plays," which comprise all maneuvers of an intricate nature, are reserved for later and more important matches. Among these is the "fake (false) kick," in which the full-back takes position as if to receive the ball for a kick, but the ball is passed to a different player for a run. Another play of this kind is the "wing-shift," in which some or all of the players on one side of the center suddenly change to the other side, thus forming a mass and throwing the opposing line out of balance. To this category belong also "double passes," "false passes," "delayed passes," "delayed runs" and "criss-crosses."

Training for football in America resembles that for other sports in regard to food and hygiene. The coaching systems at the universities differ, but there is generally a head coach, who is assisted by graduates, each of whom pays special attention to one set of men, one to the men in the center of the line, one to the backs, another to the ends, &c. Candidates for the team are put through several hard exercises, punts and hard-thrown passes, in quick starts, falling on the ball, tackling a mechanical dummy, in blocking, breaking through the line, and all kinds of kicking, although in matches the kicking is generally left to one or two men who have shown themselves particularly expert. Every player is taught to dive for the ball whenever he sees it on the ground, as possession is of cardinal importance in American football, and dribbling for this reason is unknown. When running with the ball the player is taught to take short steps, and if he interferes, that is, not isolate himself from his defenders, and neither to slow up nor shut his eyes when striking the opposing line. Tackling well below the waist is taught, but it is a foul to tackle below the knee. The general rule for defensive work of all kinds is "play low."

See Walter Camp, How to Play Football, and the Official Football Guide (annual), both in Spalding's Athletic Library; his Book of College Sports (New York, 1893), his American Football (New York, 1894), and his Football (Boston, 1896)—the last in co-operation with L. F. Deland; R. H. Barbour, The Book of School and College Sports (New York, 1904); W. H. Lewis, Primer of College Football (Boston, 1896).

FOOTE, ANDREW HULL (1856-1862), American admiral, was born at New Haven, Connecticut, on the 12th of September 1860, the son of Samuel Augustus Foote (1828-1863), a prominent lawyer and Whig politician who as U.S. senator moved in 1829 to New York. "Foote's resolutions" on public lands, in the discussion of which Daniel Webster made his reply to Hayne. He entered the U.S. navy in 1832, and was commissioned lieutenant in 1839. Accepted a commission in the Chasse before the world (1837-1840) in the "John Adams," he was assigned to the Philadelphia Naval Asylum, and later (1846-1848) to the Boston Navy Yard. In 1849 he was made commander of the "Perry," and engaged for two years in suppressing the slave trade on the African coast. In 1856, as commander of the "Portsmouth," he served on the East India station, under Com. James Armstrong, and he captured the Barrier Forts near Canton. From October 1858 to the outbreak of the Civil War, he was in charge of the Brooklyn Navy Yard, becoming a full captain in 1861. In August 1861 he was assigned to the command of the naval operations of the Western waters. His exploit in capturing Fort Henry (on the right bank of the Tennessee river) from the Confederates, on the 6th of September 1862, without the co-operation of General Grant's land forces, who had not arrived in time, was a brilliant success; but their combined attack on Fort Donelson (12 m. off, on the left bank of the Cumberland river), whither most of the Fort Henry garrison had escaped, resulted, before its surrender (Feb. 16), in heavy losses to Foote's gunboats, Foote himself being severely wounded. In March-April he co-operated in the capture of New Madrid (q.v.) and Island No. 10. In June he retired from his command and in July was promoted rear-admiral, and became chief of the Bureau of Equipment and Recruiting. On the 26th of June 1863; he died at New York.

See the life (1874) by Professor James Mason Hoppin (1820-1900).

FOOTE, MARY HALLOCK (1821-1899), American author and illustrator, was born in Milton, New York, on the 10th of November 1847, of English Quaker ancestry. She was educated at the Poughkeepsie (N.Y.) Female Collegiate Seminary and at the Cooper Institute School of Design for women, in New York. In 1876 she married Arthur De Wint Foote, a mining engineer, and subsequently lived in the mining regions of California, Idaho, Colorado and Mexico. She is best known for her stories, in which, as in her drawings, she portrays vividly the rough picturesque life, especially the mining life, of the West. Some of her best drawings and illustrations of her narratives, her publications are The Led-Horse Claim (1883), John Bodewin's Testimony (1886), The Chosen Valley (1882), Cœur d'Alene (1884); The Prodigal (1900), a novelette; The Desert and the Snow (1902); and several collections of short stories, including A Touch of Sun and other Stories (1903).

FOOTE, SAMUEL (1770-1777), English dramatist and actor, was baptized at Truro on the 27th of January 1770. Of his attachment to his native Cornwall he gives no better proofs than his style as an author than by making the comical of his hampiry Timothy (in The Knights) sound the praises of that county and of its master pastimes; but towards his family he showed a loyal and enduring affection. His father was a man of good family and position. His mother, Eleanor Goodere, whom he is said in person as well as in disposition to have strongly resembled, he liberally supported in the days of his prosperity, and after her death indignantly vindicated her character from the imputations which she was compelled to suffer in her own books. In his best works he showed such a striking succession of actions, that his name is as a character, that his name is as a character
two years after that of Garrick, as to whose merits the critics, including Foote himself, were now fiercely at war. His own first venture, as Otello, was a failure; and though he was fairly successful in genteel comedy parts, and was, after a favourable reception at Dublin, enrolled as one of the regular company at Drury Lane in the winter of 1745-1746, he had not as yet made any palpable hit. Finding that his talent lay neither in tragedy nor in genteel comedy, he had begun to wonder "where the devil it did lie," when his successful performance of the part of Bayes in The Rehearsal at last suggested to him the true outlet for his extraordinary gift of mimicry. Following the example of Garrick, he had introduced into this class of characters imitations of actors, and had added a variety of other satirical comment in the way of "gag." Engaging a small company of actors, he now boldly announced for the 22nd of April 1747, at the theatre in the Haymarket "gratis," to a new entertainment called the Diversions of the Morning," to which were to be added a farce adapted from Congreve, and an epilogue "spoken by the B-d-d Coffee-house." Foote's success in these Diversions obtained for him the name of "the English Aristophanes," an absurd compliment, declined by Foote himself (see his letter in the Diversions of the Morning). It was followed by a series of acts of actors and other well-known persons, whose various peculiarities of voice, gesture, manner or dress were brought directly before the spectators, while the epilogue introduced the wits of the Bedford engaged in ludicrous disputation, and specially "took off" an eminent physician (probably the munificent Sir William Browne, whom he afterwards caricatured in The Devil on Two Sticks), and a notorious quack occultist of the day. The actors ridiculed in this entertainment having at once procured the aid of the constables for preventing its repetition, Foote immediately advertised an invitation to his friends to drink a dish of tea with him at the Haymarket on the following day at noon—"and 'tis hoped there will be a great deal of comedy and some joyous spirits; he will endeavour to make the morning as diverting as possible. Tickets for this entertainment to be had at St. George's coffee-house, Temple-Bar, without which no person will be admitted. N.B.—Sir Dibury Diddle will be there, and Lady Betty Frisk has absolutely promised." The device succeeded to perfection; further resistance was abandoned as futile by the actors, whom Foote mercerlessly ridiculed in the "Instructions to his Pupils," which the entertainer pretended to impart (typifying them under characters embodying their several chief peculiarities or defects—the massive and sonorous James Quin as a watchman, the shrill-voiced Lacy Ryan as a razor-grinder, the charming Peg Woffington, whose tones had an occasional squeak in them, as an orange-woman crying her wares and the bill of the play); and Mr Foote's Chocolate, which was afterwards converted into an evening Tea, became an established favourite with the town.

In spite of this success, he seems to have contrived to spend a third fortune, and to have found it necessary to eke out his means by a speculation in small-beer, as is recorded in an amusing anecdote told of him by Johnson. But he could now command a considerable income; and when money came he seems to have freely expended it in both hospitality and charity. During his engagements at Covent Garden and at Drury Lane, of which he was joint-manager, and in professional trips to Scotland, and more especially to Ireland, he appeared both in comedies of other authors and more especially in his own. He played Hartop in his Knives (1749, printed 1754). Taste (1752), in which parts of the Diversions were incorporated, was followed by some eighteen pieces, the popularity of which were produced in the Haymarket, the favourite home of Foote's entertainments. In 1760 he succeeded in obtaining for this theatre a licence from the lord chamberlain, afterwards (in 1766) converted into a licence for summer performances for life. The entertainments were a succession of variations on the original idea of the Diversions and the Tea. Now, it was an Auction of Pictures (1748), of part of which an idea may be formed from the second act of the comedy Taste; now, a lecture on Orators (1754), suggested by some bombastic discourses given by Macklin in his old age at the Piazza coffee-house in Covent Garden, where Foote had amused the audience and confounded the speaker by interposing his humorous comments. The Orators is preserved in the shape of a hybrid piece, which begins with a mock lecture on the art of oratory and its representatives in England, and ends with a diverting scene of a pot-house forum debate, to which Holberg's Politician-Tinman can hardly have been a stranger. At a later date (1773) a new device was introduced in a Puppet-show. The piece (unprinted) played in this by the puppets was called Fiety in Patiens, and professes to show "the moral how maidens of low degree might become rich from the practice of morality and virtue, and by the literature how thoughts of the most commonplace might be concealed under cover of words the most high flown." In other words, it was an attack upon sentimental comedy, which was still not altogether extinguished. An attack upon Garrick in connexion with the notorious Shakespeare jubilee was finally left out from the Puppet-show, and thus was avoided a recurrence of the quarrel which many years before had led to an interchange of epistolary thrusts, and an imitation by Woodward of the imitative Foote. Though the relations between the two public favourites became very friendly, and on Foote's part unmistakably affectionate, and they have not been always generously represented by Garrick's biographers. A comparison between the two as actors is of course out of the question; but, though Foote was a buffoon, and his tongue a scurrilous tongue, there is no authentic ground for the suggestion that his character was one of malicious heartlessness. Of Samuel Johnson's opinions of him many records remain in Boswell; when Johnson had at last found his way into Foote's company (he afterwards found it to Foote's own table) he was unable to "resist" him, and, on hearing of Foote's death, he thought the career just closed worthy of a lasting biographical record.

Meanwhile most of poor Foote's friendships in high life were probably those that are sworn across the table, and require "t'other bottle" to keep them up. It is not a pleasant picture—of Lord Muxborough and his royal guest the duke of York—and their companions, bantering Foote on his ignorance of horsemanship, and after he had weakly protested his skill, taking him out to hounds on a dangerous animal. He was thrown and broke his leg, which had to be amputated, the "patientee" (in which character he said he was now making his first appearance) consoling himself with the reflection that he would now be able to take off "old Faulkner" (a pompous Dublin alderman with a wooden leg, whom he had brought on the stage as Peter Paragraph in The Orators) "to the life." The duke of York made him the best reparation in his power by promising him a life-patent for the theatre in the Haymarket (1766); and Foote not only resumed his profession, as if, like Sir Luke Limp, he considered the leg he had lost "a redundancy, a mere nothing at all," but ingeniously turned his misfortune to account in two of his later pieces, The Lame Lovers and The Devil on Two Sticks, while, with the true instinct of a public favourite, making constant reference to it in plays and prologues. Though the characters played by him in several of his later plays are comparatively short and light, he continued to retain his hold over the public, and about the year 1774 was beginning to think of withdrawing, at least for a time, to the continent, when he became involved in what proved a fatal personal quarrel. Neither in his entertainments nor in his comedies had he hitherto (except in Garrick's case, and it is said in Johnson's) put any visible restraint upon what he therein produced. In which he was the infinitely humorous character of Cadwallader, he had brought a Welsh gentleman of the name of Ap-Rice on the stage, had, indeed, been ultimately suppressed. But in general he had pursued his hazardous course, mercilessly exposing to public ridicule and contempt not only fribbles and pedants, quacks or supposed quacks in medicine (as in The Devil on Two Sticks), enthusiasts in religion, such as Dr Dodd (in The Cozeners) and George Whitefield and his connexion (in The Minor). He had not only dared the wrath of the whole Society of Antiquaries (in The
Nabob), and been rewarded by the withdrawal, from among the pundits who rationalized away Whittington's Cat, the illustrious Walpole and other eminent members of the body, but had in the same play attacked a well-known representative of a very influential though detested element in English society,—the "Nabobs" themselves. But there was one species of cracked porcelain which he was not to try to hold up to contempt with impunity. The humour of his intention to bring upon the stage, in the character of Lady Kitty Crocodile in The Trip to Calais, the notorious Duchess of Kingston, whose trial for bigamy was then (1775) impending, aroused his intended victim to the utmost fury; and the means and influence he had at his disposal enabled her, not only to prevail upon the lord chancellor to prohibit the performance of the piece (in which there is no hint as to the charge of bigamy itself), but to hire agents to vilify Foote's character in every way that hatred and malice could suggest. After he had withdrawn the piece, and letters had been exchanged between the duchess and him equally characteristic of their respective writers, Foote took his revenge upon the chief of the duchess's instruments, a "Reverend Doctor" Jackson, who belonged to the "reptile class" of the journalists of the day, so admired satirized by Foote in his The Bankrupt. This man he gibed at in the character of Viper in The Capuchin, under which name the altered Trip to Calais was performed in 1776. But the resources of his enemies were not yet at an end; and a discharged servant of Foote's was subpoenaed by Jackson to bring a charge of assault and apply for a warrant against him. Though the attempt utterly broke down, and Foote's character was thus completely cleared, his hatred of sizars had given way in the struggle—as to which, though he seems to have had the firm support of the better part of the public, including such men as Burke and Reynolds, the very audiences of his own theatre had been, or had seemed to be, divided in opinion. He thus resolved to withdraw, at least for a time, from the effects of the storm, let his theatre to Colman, and after making his last appearance there in May 1777, set forth in October on a journey to France. But at Dover he fell sick on the day after his arrival there, and after a few hours died (October 21st). His epitaph in St Mary's church at Dover (written by his faithful treasurer William Jewell) records that he had a hand "open as day for melting charity." His resting-place in Westminster Abbey is without any memorial.

Foote's chief power as an actor lay in his extraordinary gift of mimicry, which extended to the mental and moral, as well as the mere outward and physical peculiarities of the personages whose likenesses he wished to imitate. It must have been his great delight of voice, though his tones are said to have been harsh when his voice was not disguised, and an incomparable readiness for rapidly assuming the character of his heroes, both in the serious and comic pieces, and in his comedies, where he occasionally "doubled" them. His mistakes were also his excellences. Part of some of his plays, such as The Liar and The Coceros, must have greatly depended for its effect upon rapidity of delivery. In person he was rather short and stout, and coarse-featured; but his over-flowing humour is said to have found full expression in the irresistible spark of his eyes.

As a dramatic author he can only be assigned a subordinate rank. He regarded comedy as "an exact representation of the peculiar manners of that people among whom it happens to be performed; a faithful imitation of singular absurdities, particular follies, which are in the world instead of criminal; and for the correction of individuals and as an example to the whole community." This he regarded as the "true, or useful purpose of comedy; the dulce he conceived to be "the fable, the construction, machinery, conduct, plot, and incidents of the piece." For part at least of this view (advanced by him in the spirited and scholarly "Letter" in which he replied, "to the Reverend Author of the Remarks, Critical Reflections on The Liar," the overwhelming modern criticism of Foote seemed to appeal to classical authority. But he overlooked the indispensableness of the dulce to the comic drama under its primary aspect as a species of art. His comic genius was particularly happy in discovering and representing comic vice, and making the novelty about to be displayed. He not only took them from real life, but closely modelled them on well-known living men and women, was not in himself an artistic self-sufficing playwright, and the appeal of his plays is, probably no other comic dramatist has ever gone so far in this course, or has pursued it so persistently. The public delighted in his "d—d fine originals," because it recognized them as copies; and he was himself proud that he had taken them from real persons, instead of their being "vamped from antiquated plays, pillows from the French farces, or the baseless beings of the poet's brain." But the real excellence of many of Foote's comic characters lies in the fact that, besides being incomparably ludicrous types of manners, they remain admirable comic types of general human nature. Sir John Falstaff, Sir Charles Wager, and the Admiral are excellent caricatures, and her preposterous vanity in her superannuated charms; Mr Cadwallader, and his view of the advantages of public schools for children may "make acquaintances that may hereafter be useful to them; for better than if they did not signify twopenny "); Major Sturges and Jerry Sneak; Sir Thomas Lofty, Sir Luke Limp, Mrs Macheen, and a score or two of other characters, are excellent comic figures, and make one wonder whatever their origin; and many of the vices and weaknesses exposed by Foote's vigorous satire will remain the perennial subject of comic treatment so long as a stage exists. The real defect of his plays lies in the commonplace or sentimental weaknesses of their construction, contempt which the great majority of them show for the invention or conduct of a plot, and in the unwarrantable subordination of the action to the mere caricature of particular characters; but the characters are ready-made, and the action is only incidental to them. With the exception of The Liar (which Foote pretended to have taken from Lope de Vega, but which was really founded on Steele's adaptation of Corneille's Le Meuteur), and perhaps of The Bankrupt, there is hardly one of Foote's "comedies" in which the conception and conduct of the action rise above the exigencies of the mere caricature. So that we are wanting, but these familiar ingredients are incapable of exciting real interest as an original farcical action is in itself unable to produce more than transitory amusement. In his earlier plays Foote constantly resorted to mere caricature, and his early part of his career shows the caricature of the servants' hall, and pronounce the arts of the drama at the great houses to be "directed by the genius of insipidity," he, like the little theatre where he held sway, was looked upon as "an eccentric, a mere country fiddler."

At the same time, he was inexhaustible in the devising of comic scenes of genuine farce. An imitation of "old masters," an election of suburban mayor, an examination at the College of Physicians, a newspaper conclave where paragraphs are concocted and reputations massacred—all these and other equally happy situations are before the mere reader with unfailing vividness. And everywhere the comic character is instinct with its own life, and, and the comic characters are true to themselves with a buoyancy which at once raises them above the level of mere theatrical conventionalism. Foote professed to despise the mere caricaturing of national peculiarities as such, and generally used dialect as a mere additional colouring; he was, however, too wide awake to the demands of his public not to treat France and Frenchmen as fair game, and coarsely to appeal to national prejudice. His satire against those everlasting victims of English comedy and farce, the Englishman in Paris and the Englishman returned from Paris, was particularly well warranted at the time, but the fact that Englishmen are nowhere more addicted to the society of their countrymen than abroad. In general, the purposes of these two comedies, the one to bring to light, the other to exaggerate and ridicule, as he did, the abuses against which it is directed are those which it required courage, if not skill, and a great bulk of his morality, especially and his language, though not aiming at refinement, is remarkably free from intentional grossness. He made no more than a pretense of having written them, and his scorn against the pretentiousness of Court and the effrontery of Vice, the two master evils of the age and the society in which he lived. The following is a list of Foote's farces or "comedies" as he calls them, mostly in three, some in two acts, which remain in print. The date of production, and the character originally performed by Foote, are added to the title of each:

1. The Night-light (1748; Harlow, who assumes the character of Sir Penurious Trille); Taste (1752), in which part of the Diversions is incorporated; The Englishman in Paris (1753; Young Buck); The Duenna (1756; Dr. Ralph); The Champion's Return (1758; by T. P.); The Liar (1759); The Pupil (1760; Mr. and Mrs. Cole); Sir Charles Wager (1763); The Doctor (1764); The Bankrupt (1773; Sir Robert Racketeer); The Commissary (1765; Mr. Zac. Fungus); The Devil upon Two Sticks (1768; Devil,—alias Dr Hercules Hellebore); The Lame Lover (1769; Sir Luke Limp); The Mikado (1772; Sir John Falstaff); The Bankrupt (1773; Sir Robert Racketeer); The Coceros (1774; Mr. Aircastle); The Capuchin, a second version of The Trip to Calais, forbidden by the censor (1776; Old Falstaff were caught and put away).}

Bibliography.—Foote's biography may be read in W. ("Conversation"") Cooke's Memoirs of Samuel Foote (3 vols., 1805), which contains a list of Foote's plays, with notices of his life and character, and of anecdotes concerning him, besides two of his previously unpublished occasional pieces (with the Tragedy & la mode, part of the Diversions, in which Foote appeared as Fustian). From this source seems to have been mainly taken the biographical information in the rather grandiloquent essay on Foote prefixed by "Jon Bee"
FOOTMAN—FORAMINIFERA

(John Badcock, fl. 1816–1830, also known as "John Hunds") to his useful edition of Foote's Works (3 vols., 1830). Various particulars will be found in Tate Wilkinson's Wandering Painter (York, 1795) and in other sources. There is an admiring essay on Foote, reprinted with additions, from the Quarterly Review, in John Forster's Biographical Essays (1858). A recent life of Foote is by Percy Fitzgerald (1910).

FOOTMAN, a name given among articles of furniture to a metal stand, usually of polished steel or brass, and either oblong or oval in shape, for keeping plates and dishes hot before a dining-room fire. In the days before the general use of hot-water dishes the footman possessed definite utility, but although it is still in occasional use, it is now chiefly regarded as an ornament. It was especially common in the hardware counties of England, where it is still frequently seen; the simple conventionality of its form is not inelegant.

FOOTSCRAY, a city on Bourke county, Victoria, Australia, on the Saltwater river, a m. W. of and suburban to Melbourne. Pop. (1901) 18,301. The city has large bluestone quarries from which most of the building stones in Melbourne and the neighbourhood is obtained; it is also an important manufacturing centre, with numerous sugar-mills, jute factories, soap works, woollen-mills, foundries, chemical works and many other minor industries.

FOOT-STALL, a word supposed to be a literal translation of piedestal, or pedestal, the lower part of a pier in architecture (see Base).

FOPPA, VINCENTO, Italian painter, was born near Brescia. The dates of his birth and death used to be given as 1400 and 1492; but there is now good reason for substituting 1427 and 1545. He settled in Pavia towards 1456, and was the head of a Lombard school of painting which subsisted up to the advent of Leonardo da Vinci. In 1489 he returned to Brescia. His contemporary reputation was very considerable, his merit in perspective and foreshortening being recognized especially. Among his noted works are a fresco in the Brera Gallery, Milan, the "Martyrdom of St Sebastian"; and a "Crucifix" in the Carrara gallery, Bergamo, executed in 1456. He worked much in L'Assi de Bonaparte, and in Genoa, but many of his paintings are now lost.

See C. J. Fiolkes and R. Maiocechi, Vincenzo Foppa (1910).

FORAGE, food for cattle or horses, chiefly the provender collected for the food of the horses of an army. In early usage the word was confined to the dried forage as opposed to grass. From this word comes "foray," an expedition in search of "forage," and hence a pillaging expedition, a raid. The word "forage," directly derived from the Fr. fourrage, comes from a common Teutonic origin, and appears in "fodder," food for cattle. The ultimate Indo-European root, pat., cf. Gr. ραγεῖν, Lat. pasce, to feed, gives "food," "feed," "foster"; and appears also in such Latin derivatives as "pastor," "pasture."

FORAIN, J. L. (1852— ), French painter and illustrator, was born in 1852. He became one of the leading modern Parisian caricaturists, who in his merciless exposure of the weaknesses of the bourgeoisie continued the work which was begun by Daumier under the second Empire. The seething bitterness of his satire is as clearly derived from Daumier as his pictorial style can be traced to Manet and Degas; but even in his painting he never suppresses the caustic spirit that drives him to caricature. He has, indeed, been rightly called "a Degas pushed on to caricature." In his pen-and-ink work he combines extraordinary economy of means with the utmost power of expression and suggestion. Forain's popularity dates from the publication of his Comédie parisienne, a series of two hundred and fifty sketches republished in book form. He has contributed many admirable, if sometimes over-daring, pages to the Figs. Le Journal des débats, Le Courrier français, and L'Événement. His political drawings for the Figaro were republished in book form under the title of Deux Pays.

FORAKER, JOSEPH BENSON (1836— ), American political leader, was born near Rainsboro, Highland county, Ohio, on the 5th of July 1846. He passed his early life on a farm, enlisted as a private in the 89th Ohio Volunteer Infantry in July 1862, served throughout the Civil War, for part of the time as an aide on the staff of General H. W. Slocum, and in 1865 received a captain's brevet for "efficient services during the campaigns in North Carolina and Georgia." After the war he spent two years at the Ohio Wesleyan University and two years at Cornell. In 1869 he was admitted to the Ohio bar and began practice in Cincinnati. He was a judge of the Cincinnati Superior Court from 1879 to 1882. In 1883 he was the Republican candidate for governor of Ohio, but was defeated; in 1885 and 1887, however, he was elected, but was again defeated in 1889. He then for eight years practised law with great success in Cincinnati. In 1896 he was elected United States senator to succeed Calvin S. Brice (1845–1898); in 1902 he was re-elected and served until 1909. In the Senate he was one of the aggressive Republican leaders, strongly supporting the administration of President McKinley (whose name he presented to the Republican National Conventions of 1896 and 1900) in the debates preceding, during, and immediately following the Spanish-American War, and later, during the administration of President Roosevelt, was conspicuous among Republican leaders for his independence. He vigorously opposed various measures advocated by the president, and led the opposition to the president's summary discharge of certain negro troops after the Brownsville raid of the 13th of August 1906 (see BROWNSVILLE, Texas).

FORAMINIFERA, in zoology, a subdivision of Protozoa, the name selected for this enormous class being that given by A. D'Orbigny in 1826 to the shells characteristic of the majority of the species. He regarded them as minute Cephalopods, whose chambers communicated by pores (foramina). Later on their true nature was discovered by D. Dujardin, working on living forms, and he referred them to his Rhizopoda, characterized by pseudopodia given off from the sarcod (proto-plasm) as organs of prehension and locomotion. W. B. Carpenter in 1862 differentiated the group nearly in its present limits as "Reticularia"; and since then it has been rendered more natural by the removal of a number of simple forms (mostly freshwater) with branching but not reticulate pseudopods, to Floosa, a distinct subclass, now united with Lobosa into the restricted class of Rhizopoda.

Anatomy.—Protista Sarcodina, with simple protoplasmic bodies of granular surface, emitting processes which branch and anastomose freely, either from the whole surface or from one or more elongated processes ("stylopods"); nucleus one or more (not yet demonstrated in some little known simple forms), usually in genetic relation to granules or strands of matter of similar composition, the "chromidia" scattered through the protoplasm; body naked, or provided with a permanent investment (shell or test), membranous, gelatinous, arenaceous (of compacted or cemented granules), calcareous, or very rarely (in deep sea forms) silicious, sometimes freely perforated, but never latticed; opening by one or more permanent apertures ("pylomes") or crevices between compacted sand-granules, often very complex; reproduction by fission (only in simplest naked forms), or by brood formation; in the latter case one mode of brood formation (A) eventuates in amoebiform embryos, the other (B) in flagellate zoospores which are exogamous.

Fig. 1A.—Lieberkühnia, with reticulate pseudopodia.
gametes, pairing but not with those of their own brood; the coupled cell ("zygote") when mature in the shelled species gives rise to a very small primitkve test-chamber or "microsphere." The adult microspheric animal gives rise to the amoebiform brood which has a larger primitkve test ("megalo sphere"); and megalo- sphere forms appear to reproduce by the A type a series of similar forms before a B brood of gametes is finally borne, to pair and reproduce the microspheric type, which is consequently rare.

The shells require special study. In the lowest forms they are membranous, sometimes encrusted with sand-grains, always very simple, the only complication being the doubling of the pyleome in Diplophrys (fig. 3, 4), Shephardella (fig. 2, 3, 5), Amphirena (fig. 2, 11), Diaphorophodon (fig. 2, 12). The marine shells are, as we have seen, of cemented particles, or calcareous, glassy, and regularly perforated, or again calcareous, but porcel- lanous and rarely perforate. These characters have been used

as a guide to classification; but some sandy forms have so large a proportion of calcareous cement that they might well be called encrusted calcareous genera, and are also not very constant in respect of the character of perforation. The porcellaneous genera, however, form a compact group, the replacement of the shell by silica in forms dwelling in the red clay of the ocean abysses, where calcium carbonate is soluble, not really making any difficulty. Moreover, the shells of this group show a deflected process or neck of the embryonic chamber ("camptopyle") at least in the megalo sphere forms, whereas when such a neck exists in other groups it is straight. The opening of the shell is called the pyleome. This may be a mere hole where the lateral walls of the body end, or there may be a diaphragmatic ingrowth so as to narrow the entrance. It may be a simple rounded opening, oblong or tri-multi-radiate, or branching (fig. 4, 1); or replaced by a number of coarse pores ("ethmopyle") (fig. 3, 5). Again, it may lie at the end of a narrowed tube ("stylopyle"), which in Lagen (fig. 3, 6) may project outwards ("ectosomal"), or inwards ("endosomal"). In most groups the stylopyle is straight; but in the majority of the porcellaneous shells it is bent down on the side of the shell, and constitutes the "flexopyle" of A. Kemna, which being a hybrid term should be replaced by "camptopyle." The animal usually forms a simple shell only after it has attained a certain size, and this "embryonic chamber" cannot grow further. In Spirilina and Ammodiscus there is no pylocic end-walls, and the shell continues to grow as a spiral tube; in Cornuspira (fig. 3, 1) there is a slight constriction indicating the junction of a small embryonic chamber with a camptopyle, but the rest of the shell is a simple flat spiral of several turns. In the majority at least one chamber follows the first, with its own pyleome at the distal end. This second chamber may rest on the first, so that the part on which it rests serves as a party-wall bounding the front of

highest vitreous shells, however, each chamber has its complete "proper wall"; while a "supplementary skeleton," a deposit of shelly matter, binds the chambers together into a compact whole. In all cases the protoplasm from the pylome may deposit additional matter on the outside of the shell, so as to produce very characteristic sculpturing of the surface.

Compound or "polythalic" shells derive their general form largely from the relations of successive chambers in size, shape and direction. This is well shown in the porcellaneous Miliolidae. If we call the straight line uniting the two ends of a chamber the "polar axis," we find that successive chambers are crozier-shaped. In others (which may have the same sculpture, and are scarcely distinguishable as species) the chambers are short and wide, drawn out at right angles to the axis, but in the plane of the spiral, and the growing shell becomes fan-shaped or "flabelliform" (figs. 3, 5, 4, 2). This widening may go on till the outer chambers form the greater part of a circle, as in Orbitolina (fig. 3, 6-8) where, moreover, each large chamber is subdivided by incomplete vertical bulkheads into a tier of chamberlets; each chamberlet has a distinct pylomic pore opening to the outside or to those of the next outer zone. In Orbitolites (figs. 5, 6) we have a centre on a somewhat Milolites type; and after a few chambers in spiral succession, complete circles of chambers are formed. In the larger forms the new zones are of greater height, and horizontal bulkheads divide the chamberlets into vertical tiers, each with its own pylomic pore.

The Cheiostomelloidae (fig. 3, 13) reproduce among perforate vitreous genera what we have already seen in the Miliolidae: Orbitolites (fig. 10, 2) and Cyclodiscus, among the Nummulites group, with a very finely perforate wall, recall the porcellaneous Orbitolina and Orbitolites.

In flat spiral forms (figs. 22, 7, 3, 2, 16, 19, &c.) all the chambers may be freely exposed; or the successive chambers be wider transversely than their predecessors.

FIG. 4.—Modifications of Peneroplis. 1, Dendrillina; 2, Eu-Peneroplis.

FIG. 5.—Shell of simple type of Orbitolites, showing primordial chamber a, and circumambient chamber b, surrounded by successive rings of chamberlets connected by circular galleries which open at the margin by pores.

FIG. 6.—Animal of simple type of Orbitolites, showing primordial segment a, and circumambient segment b, surrounded by annulus of sub-segments connected by radial and circular stolon-processes.

have their pylomes at alternate poles; but they lie on different meridians. In Spirocyclina (fig. 3, 2) the divergence between the meridians is 180°, and the chambers are strongly incurved, so that the whole shell forms a flat spiral, of nearly circular outline. In the majority, however, the chambers are crescentic in section, their transverse prolongations being termed "alary" outgrowths, so that successive chambers overlap; when under this condition the angle of successive meridians is still 180° we have the form Biloculina (fig. 3, 4), or with the alary extensions completely enveloping, Uniloculina; when the angle is 120° we have Triloculina, or 144°, Quinqueloculina. Again in Peneroplis (figs. 3, 6, and 4) the shell begins as a flattened shell which tends to straighten out with further growth and additional chambers. In some forms (Spinulina, fig. 22, 3) the chambers have a nearly circular transverse section, and the adult shell is
and overlap by “alary extensions,” becoming “nautiloid”; in extreme cases only the last turn or whorl is seen (fig. 11). When the spiral axis is conical the shell may be “nautiloid,” the larger lower chambers partially concealing the upper smaller ones (fig. 3, 15, 17, 18); or they may leave, as in Pseudolina, a wide central conical cavity—which, in this genus, is finally occupied by later formed “supplemental” chambers. When the successive chambers are disposed around a longitudinal central axis they may be said to “alternate” like the leaves of a plant. If the arrangement

Two phenomena interfere with the ready availability of the characters of form for classificatory ends—dimorphism and multiformity.

Dimorphism.—The majority of foraminiferan shells show two types, the rarer with a much smaller central chamber than that of the more frequent. The chambers are called microsphere

and megalosphere, the forms in which they occur microspheric and megalospheric forms, respectively. We shall study below their relation to the reproductive cycle.

Multiformity.—Many of the Polythalamia show different types of chamber-succession at different ages. We have noted

and as such these phenomenon in such crozier forms as Peneroplis, as well as in discoid forms; it is very frequent. Thus the microspheric Biloculina form the first few chambers in quinqueloculin succession. The microspheric forms attain a greater size when adult than the megalospheric; and in Orbitolites the microsphere has a straight outlet, orthostyle, instead of the deflected campto style one, so general in porcellaneous types; and the spiral succession is continued for more turns before reaching the fan-shaped and finally cyclic stage. Globigerina, whose chambers are nearly spherical, is sometimes seen to be enclosed in a spherical test, perforate, but without a pylome, and known as Orbulina; the chambered Globigerina-shell is d, d, Larger pores; attached at first inside the wall of the Orbulina, but ultimately disappears. The ultimate fate of the Orbulina shell is unknown; but it obviously marks a turning-point in the life-cycle.

Protoplasmic Body and Reproduction.—The protoplasm is not differentiated into ecto- and endosarc, although it is often denser
in the central part within the shell, and clearer in the pseudopodial ramifications and the layer (or stalk in the monothalamic forms) from which it is given off. In pelagic forms like Globodistina the external layer is almost if not quite identical in structure with the exocapsular protoplasm of Radiolaria (q.v.), being differentiated into granular strands traversing a clear jelly, rich in large vacuoles (alveoli), and uniting outside the jelly to form the basal layer of the pseudopods; these again are radiolarian in character. Hence E. R. Foraminifera, the shell here to the central capsule of the Radiolarian, though

The sandy shells are a very interesting series. In Astrorhiza the sand grains are loosely agglutinated, without mineral cement; they leave numerous pores for the exit of the protoplasm, and there are no true pylomes. In othems utilize the union of the grains by a calcareous or ferruginous cement necessitates the existence of distinct pylomes. Many of the species reproduce the varieties of form found in calcareous tests; some are finely perforated, others not. Many of the larger ones have their walls thickened internally and traversed by complex passages; this structure is called labry-

Fig. 13.—Internal cast of two chambers, a, a, of Nummulites, the radial canals between them passing into b, marginal plexus.

Fig. 15.—Cytochypeus.

Fig. 16.—Heterostegina.

I. NUDA.—Protoplasmic body without any pedicle or shell save in the resting encysted condition, sometimes forming colonial aggregates by coalescence of pseudopods (Myxodictyum), or even plasmolida (Protoxyza). Brood cells at first unflagellate or amoeboid from birth. Fresh-water and marine genera Protogone (Haeckel), Biomyxa (Leidy), Myxodictyum (Haeckel), Protomyxa (Haeckel) (fig. 18). This group of very simple forms includes many of Haeckel’s Monera, defined as “cytodes,” masses of protoplasm without a nucleus. A nucleus (or nuclei) has, however, been demonstrated by improved methods of staining in so many that it is probable that this distinction will fail to the ground.

II. ALLOGROMIDIACEAE (figs. 1a, 2).—Protoplasmic body protected in adult state by an imperforate test with one or two openings (pylomes) for the exit of the stylopod; test simple, gelatinous, membranous, sometimes incrusted with foreign bodies; never calcareous nor arenaceous; reproduction by fusion alone known. Fresh-water or marine genera Allogromia (Rhumb), Myxoe- theca (Schaud), Lieberkühnia (Cl. & L.) (fig. 1a), Sheperdella (Siddall) (fig. 2, 3, 10), Diplophyes (Barker), Amphitritea (Arch.) (fig. 2, 11), Diaphorophydon (Arch. (fig. 2, 12), are possibly Filosa. This group differs from the preceding in its simple test, but, like it, includes many fresh-water species, which possess contractile vacuoles.

III. ASTRORHIZIDACEAE.—Simple forms, rarely polythalamous (some Rhadamminidae), but often branching or radiate; test arenaceous, loosely compacted and traversed by stalks for pseudopodia (Astrorhizidae), or dense, and opening by one or more terminal pylomes at ends of branches. Marine, 4½ mm. The test of some Astrorhiza is so loose that it falls to pieces when taken out of water. Haliphysema is remarkable for its history in relation to the “gastracan theory.” Pilula has a naked globular shell of sponge-spicules and fine sand. Genera, Astrorhiza (Sandali)
FORAMINIFERA

VIII. LAGENIDACEAE.—Shells vitreous, often sculptured, mono- or polythalamically, finely perforate; chambers flask-shaped, with a protruding or an inturned stylople; *Lagenia* (Walker & Boys) (fig. 4, 9); *Nodosaria* (Lamk.) (figs. 23, 4; 4, 10); *Polymorphina* (d'Orb.) (fig. 4, 13); *Cristellaria* (Lamk.) (fig. 4, 11); *Fondsiustaria* (Def.) (fig. 23, 8).

IX. GLOBIGERINIDACEAE.—Shells vitreous, coarsely perforated; chambers few, spherical rapidly increasing in size; arranged in a trochoid or nautiloid spiral. *Globigerina* (Lamk.) (23, 6; 4, 13); *Hastigerina* (Wyville Thompson) (figs. 25, 6); *Orbulina* (d'Orb.) (fig. 23, 8).

X. ROTALIDACEAE.—Shells vitreous, finely perforate; walls thick, often double, but without an intermediate party-layer traversed by canals; form usually spiral or trochoid. *Dissorhiza* (Parker & Jones) (fig. 4, 16); *Planorbulina* (d'Orb.) (figs. 4, 17); *Rotalia* (Lamk.) (figs. 23, 1, 2; 7, 21); *Calcarea* (d'Orb.) (fig. 23, 10); *Polydema* (Rise) (fig. 23, 9).

XI. NUMMULIDACEAE.—As in Rotaliaceae, but with a thicker finely perforated shell, often well developed, and a supplementary skeleton traversed by branching canals as an additional party-wall between the proper chamber-walls. *Nonionema* (d'Orb.) (fig. 4, 19); *Pseudolina* (Fischer) (fig. 20); *Polysomella* (Lamk.) (figs. 4, 16; 8); *Operculina* (d'Orb.) (fig. 9); *Heterostegina* (d'Orb.) (fig. 16); *Cycloplectus* (Carptr.) (fig. 15); *Nummulites* (Lamk.) (figs. 10, 12, 13, 14).

"Eozoocystis," described as a species of this order by J. W. Dawson and Carpenter, has been pronounced by a series of enquirers, most of whom started with a belief in its organic structure, to be merely a complex mineral concretion in ophicalcite, a rock composed of an admixture of silicates (mostly serpentine and pyroxene) and calcite.

**Distribution in Vertical Space.**—Owing to their lack of organs for active locomotion the Foraminifera are all crawling or attached, with the exception of a few genera (very rich in species, however) which float near the surface of the ocean, constituting part of the pelagic plankton (q.v.). Thus the majority are littoral or deep-sea, sometimes attached to other bodies or even burrowing in the tests of other Foraminifera; most of the fresh-water forms are sapropelic, inhabiting the layer of organic

C. Later stage, resolving itself into two flagellate gametes.
D. Conjugation. [zygote.]
E. Microspheric individual produced from 2. Nuclei.
F. The same resolved itself into pseudochamber; *Cornuspira* (Schultze) (fig. 3); *Miliola* (Lamk.), including as subgenere *Spiriloculina* (d'Orb.) (figs. 3 and 22); *Triloculina* (d'Orb.) (fig. 3); *Biloculina* (d'Orb.) (fig. 3); *Uniloculina* (d'Orb.); *Quinquiloculina* (d'Orb.); *Peneroplis* (Montfort) (figs. 22, 8, 3), with form *Dendritina* (fig. 4, 1); * Orbiloculina* (Lamk.) (figs. 5, 6); *Orbiloculina* (d'Orb.) (fig. 22); *Squamulina* (Sch.) (fig. 22); *Calceola* (Schaudinn).

VI. TEXTULARIADACEAE.—Shells perforate, vitreous or (in the larger forms) arenaceous, in two or three alternating ranks (distichous or tristichous). *Textularia* (Defrance) (fig. 21).

VII. CHELOSTOMELLACEAE.—Shells vitreous, thin, the chambers doubling forwards and backwards as in *Millicolidae*. *Chelostoma* (Reuss).
débris at the surface of the bottom mud ditches of pools, ponds and lakes. The deep-sea species below a certain depth cannot possess a calcareous shell, for this would be dissolved; and it is in these that we find limesalts sometimes replaced by silica.

The pelagic floating genera are also specially modified. Their shell is either thin or extended many times by long slender tapering spines, and the protoplasm outside has the same character as that of the Radiolaria (q.v.), being differentiated into jelly containing enormous vacuoles and traversed by reticulate strands of granular protoplasm. These coalesce into a peripheral zone from which protrude the pseudo-

in glauconite (a green ferrous silicate, whose composition has not yet been accurately determined) are, however, frequently left. Glauconitic casts of perforate shells, notably Globigerina, have been found in Lower Cambrian (e.g. Hollybush Sandstone), and the shells themselves in Siberian limestones of that age. It is only when we pass into the Silurian Wenlock limestone that sandy shells make their appearance. Above this horizon Foraminifera are more abundant as constituents, partial or principal of calcareous rocks, the genus Endothyra being indeed almost confined to Carboniferous beds. The genus Fusulina (fig. 20) and Saccammina (fig. 19) give their names (from their respective abundance) to two limestones of the Carboniferous series. Porcellaneous shells become abundant only from the Lias upwards. The glauconitic grains of the Greensand formations are chiefly foraminiferal casts. Chalk is well known to consist largely of foraminiferal shells, mostly vitreous, like the north Atlantic globigerina ooze. In the Maestricht chalk more littoral conditions prevailed, and we find such large-sized species as Orbitoides (vitreous) and Orbitolites (porcellaneous; figs. 5, 6), &c. In the Eocene Tertiaries the Calcaire Grossier of the Paris basin is mainly composed of Milolids forms. Nummulites occur in English beds and in the Paris basin; but the great beds of these, forming reef-like masses of limestone, occur farther south, extending from the Pyrenees through the southern and eastern Alps to Egypt, Sinai, and on to north India. The peculiar structure occurring in the Lower Laurentian limestone, as well as other limestones of Archean age described as a Nummulitaceae genus, "Easoon," by Carpenter and Dawson, and abundantly illustrated in the 9th edition of his encyclopaedia, is now universally regarded as of inorganic origin. "Looking
FORAMINIFERA

1. Spiroloculina planulata, Lamarck, showing five "cells"; porcellaneous.
2. Young ditto, with shell dissolved and protoplasm stained so as to show the seven nuclei.
3. Spirulina (Peneroplis); a sculptured imperfectly coiled shell; porcellaneous.
4. Verruculina, a simple shell consisting of chambers succeeding one another in a straight line; porcellaneous.
5. O. Thurammina papillata, Brady, a sandy form. 5 is broken open so as to show an inner chamber; recent. X 25.
6. Haplophragmium canariensis, a sandy form; recent.
7. Nucleated reproductive bodies (sporocytes) of Halysiphonia.
8. Spumalina laciniata, M. Schultze; X 40; a simple porcellaneous Miolide.
9. Protoplasmic core removed after treatment with weak hydrochloric acid from the shell of Halysiphonia tunamactulis, How. n. Vascular nuclei, stained with haematoxylin. (After Landecker.)
10. Halysiphonia tunamactulis; X 25 diam.; living specimen, showing the white-glassy-shaped shell built up of sand-grains and sponge-epidermis, and the abundant protoplasm, issuing from the mouth of the shell and spreading partly over its projecting constituents.
11. Shell of Astronbea limicola, Sav. X 1; showing the branching of the test on some of the rays usually broken away in preserved specimens (original).
12. Section of the shell of Marspida, showing thick walls built of sand-grains.
13. Spiral arrangement of simple chambers of a Reticularian shell, as in small Rotalias, Dino, with double septal walls, and supplemental shell-substance (shaded), as in large Rotalias.
14. Diagram to show the mode in which successively-formed chambers may completely embrace their predecessors, as in Eudesmicola.
15. Diagram of a simple straight series of non-encircling chambers, as in Nodosaria.
16. Hystigerina murayi, Wyw. Thomson. a. Bubbly (vaccumated) protoplasm, enclosing, b, the perforated Hystigerina-like shell (void central capsule of Radiolaria). From the peripheral protoplasm project, not only fine pseudopodia, but hollow spines of calcareous matter, which are set on the shell, and have an axis of active protoplasm. Polygag drawn in the living state.
17. Hystigerina bul.'); d'Orb., showing the punciform perforations of the shell and the main aperture.
18. Fragment of the shell of Globigerina, seen from within, and highly magnified. a. Fine perforations in the inner shell substance; b, outer (secondary) shell substance. Two coarse perforations are seen in section, and one lying among the smaller.
19. Orbulina universa, d'Orb. Fleshy example, with adherent radiating calcareous spines (bellow), and internally a small Globigerina shell. It is a probable developmental phase of Globigerina. 2. Orbulina shell; 3, Globigerina shell.
21. Cylindrospira signifera, Gmel.; X 10. Tertiary, Sicily. Shell dissected so as to show the spiral arrangement of the chambers, and the copious secondary shell substance. a, b, c, Chambers of three successive coils in section, showing the thin primary wall (finely tubulated) of each; k, h, k, perforate surfaces of the primary wall of four tiers of chambers, from which the secondary shell substance has been cleared away; c, e, secondary or Intermediate shell substance in section, showing coarse canals; d, section of secondary shell substance at right angles to c, e, tuberules of secondary shell substance on the surface; f, j, globule processes of secondary shell substance.
at the almost universal diffusion of existing Foraminifera and the continuous accumulation of their shells over vast areas of the ocean-bottom, they are certainly doing more than any other group of organisms to separate carbonate of lime from its solution in sea-water, so as to restore to the solid crust of the earth what is being continuously withdrawn from it by solution of the calcareous materials of the land above sea-level." (E. R. Lankester, "Protozoa," Ency. Brit. 9th ed.)

Historical.—The Foraminifera were discovered as we have seen by A. d’Orbigny. C. E. Ehrenberg added a large number of species, but it was to F. Dujardin in 1835 that we owe the recognition of their true zoological position and the characters of the living animal. W. B. Carpenter and W. C. Williamson in England contributed largely to the study of the shell, the latter being the first to call attention to its multiformal character in the development of a single species, and to utilize the method of thin sections, which has proved so fertile in results. W. K. Parker and H. B. Brady, separately, and in collaboration, described an enormous number of forms in a series of papers, as well as in the monograph by the latter of the Foraminifera of the "Challenger" expedition. Munier-Chalmas and Schumacher brought out the fact of dimorphism in the group, which was later elucidated and incorporated in the full cytological study of the life-cycle of Foraminifera by J. J. Lister and F. Schaudihr, independently, but with concurrent results.

Appendix.—The XENOPHYPORIDAE are a small group of bottom-dwelling Seracodina which show a certain resemblance to arenaceous Foraminifera, though observations in the living state show that the character of the protozooid is lacking. The multinucleate protoplasm is contained in branching tubes, aggregated into masses of definite form, bounded by a common wall of foreign bodies (sponge spicules), and vented into a mesosome. The large granules of BSO₄, and pellets of feacial matter. All that is known of reproduction is the resolution of the pellets into unicellular ciliates. (F. E. Schultze, Wissenschaftliche Ergebnisse der deutschen Tiefsee-Expedition, i. (1895), p. 1.)

FORBACH, a town of Germany in the imperial province of Alsace-Lorraine, on a affluent of the Rossel, and on the railway from Metz to Saarbrücken, 3½ m. S.W. of the latter. Pop. (1905) 8193. It has a Protestant and a Roman Catholic (Greek) church, a synagogue and a Progymnasium. Its industries include the manufacture of tiles, pasteboard wares and gardening implements, while there are coal mines in the vicinity. After the battles on the Alsace heights of Spicheren (6th of August 1870), in which the French under the German General were defeated by the Germans under General von Glümer, the town was occupied by the German troops, and at the conclusion of the war annexed to Germany. On the Schlossberg near the town are the ruins of the castle of the counts of Forbach, a branch of the counts of Saarbrücken.

See Besler, Geschichte des Schlosses, der Herrschaft und der Stadt Forbach (1808).

FORBES, ALEXANDER PENROSE (1817-1879), Scottish divine, was born at Edinburgh on the 6th of June 1817. He was the second son of John Henry Forbes, Lord Medwyn, a judge of the court of session, and grandson of Sir William Forbes of Pitligo. He studied first at the Edinburgh Academy, then for two years under the Rev. Thomas Dale, the poet, in Kent, passed one session at Glasgow University in 1833, and, having chosen the career of the Indian civil service, completed his studies with distinction at Haileybury College. In 1836 he went to Madras and secured early promotion, but in consequence of ill-health he was obliged to return to England. He then entered Brasenose College, Oxford, where in 1841 he obtained the Boden Sanskrit scholarship, and graduated in 1844. He was appointed to the Oxford district of the movement known as Puseyism, and was powerfully influenced by the works of Newman, Pusey and Keble. This led him to resign his Indian appointment. In 1844 he was ordained deacon and priest in the English Church, and held curacies at Aston, Rowant and St Thomas's, Oxford; but being naturally attracted to the Episcopal Church of his native land, then recovering from long depression, he removed in 1846 to Stonehouse, the chief town of Kincardineshire. The same year, however, he was appointed to the vicarage of St Saviour's, Leeds, a church founded to preach and illustrate Tractarianism. In 1848 Forbes was called to succeed Bishop Moir in the see of Brechin. He removed the episcopal residence to Dundee, where he resided till his death, combining the pastoral charge of the congregation with the duties of the see. When he came to Dundee the churchmen were accustomed owing to their small numbers to worship in a room over a bank. Through his energy several churches were built, and among them the pro-cathedral of St Paul's. He was prosecuted in the church courts for heresy, the accusation being founded on his primary charge, delivered and published in 1857, in which he broke with his views on the Sacrament. He made a powerful defence of the charge, and was acquitted, the court undertaking no admonition." Keble wrote in his defence, and was present at his trial at Edinburgh. Forbes was a good scholar, a scientific theologian and a devoted worker, and was much beloved. He died at Dundee on the 8th of October 1875.

Principal works: A Short Explanation of the Nicene Creed (1852); An Explanation of the Thirty-nine Articles (2 vols., 1869 and 1868); Commentary on the Seven Penitential Psalms (1847); Commentary on the Canonticles (1853). See Mackey's Bishop Forbes, a Memoir.

FORBES, ARCHIBALD (1836-1900), British war correspondent, the son of a Presbyterian minister in Morayshire, was born on the 17th of April 1836, and was educated at Aberdeen University. Entering the Royal Dragoons as a private, he gained, while in the service, considerable practical experience of military life and affairs. Being invalided from his regiment, he settled in London, and became a journalist. When the Franco-German War broke out in 1870, Forbes was sent to the front as war correspondent to the Morning Advertiser, and in this capacity he gained valuable information as to the plans of the Parissins for withstanding a siege. Transferring his services to the Daily News, his brilliant feats in the transmission of intelligence drew world-wide attention to his despatches. He was with the army from the signing of the armistice, and his accounts of the movement towards the Cape of Good Hope, the rise and fall of the Commune, and the British trenches, were of such a character as to render his name a household word in every quarter of the world. Forbes afterwards proceeded to Spain, where he chronicled the outbreak of the second Carlist War; but his work here was interrupted by a visit to India, where he spent eight months upon a mission of investigation into the Bengal famine of 1874. Then he returned to Spain, and followed at various times the Carlist, the Republican and the Alfonsoist forces. As representative of the Daily News, he accompanied the prince of Wales in his tour through India in 1875-1876. Forbes went through the Servian campaign of 1878, was present at the important engagements in the Russo-Turkish campaign of 1877; he was with the army from the outbreak of the war, and his accounts of the movements of his army, the general character of the country in which they were fighting, and the results of the battles, were of such a character as to render him a household name. On recovering from his fever, Forbes proceeded to Cyprus, in order to witness the British occupation. The same year (1878) he went to India, and in the winter accompanied the Khyber Pass force to Jalalabad. He was present at the taking of Musjid, and marched with the army in the south. On the conclusion of the campaign, Forbes was the next field of adventure, and at Mandalay, the capital, he had several interesting interviews with King Thibaw. He left Burma
hurriedly for South Africa, where, in consequence of the disaster of Isandlwana, a British force was collecting for the invasion of Zululand. He was present at the victory of Ulundi, and his famous ride of 120 m. in fifteen hours, by which he was enabled to convey the first news of the battle to England, remains one of the finest achievements in journalistic enterprise. Forbes subsequently delivered many lectures on his war experiences to large audiences. His closing years were spent in literary work. He had some years before published a military novel entitled Drawn from Life, and a volume on his experiences of the war in the story entitled "In Germany," whose loyalty could be relied upon, by numerous publications, including Glimpses through the Cannon Smoke (1886); Souvenirs of some Continents (1883); William I. of Germany: A Biography (1888); Havlock, in the "English Men of Action" Series (1890); Barracks, Bivouacs, and Battles (1891); The Afghan Wars, 1839-80 (1892); Caesar and Sultane (1893); Memories and Studies of War and Peace (1895), in many respects autobiographic; and Colin Campbell, Lord Clyde (1896). He died on the 30th of March 1900.

FORBES, DAVID (1828-1870). British mineralogist, metal-lurgist and chemist, brother of Edward Forbes (q.v. on this page). He was born at Duffus 1828, son of John Forbes, M. A., and received his early education there and at Brentwood in Essex. When a boy of fourteen he had already acquired a remarkable knowledge of chemistry. This subject he studied at the university of Edinburgh, and he was still young when he was appointed superintendent of the mining and metallurgical works at Espeal in Norway. Subsequently he became a partner in the firm of Evans & Askin, nickel-smelters, of Birmingham, and in that capacity during the years 1857-1860 he visited Chile, Bolivia and Peru. Besides reports for the Iron and Steel Institute, of which he was a member for many years, he wrote upwards of 50 papers on scientific subjects, among which are the following: "The Action of Sulphures on Metallic Silicates at High Temperatures," Rep. Brit. Assoc., 1855, p. 62; "The Relations of the Silurian and Metamorphic Rocks of the south of Norway," ib. p. 81; "The Causes producing Foliation in Rocks," Journ. Geol. Soc. xi., 1855; "The Chemical Composition of the Silurian and Cambrian Limestones," Phil. Mag. xiii. pp. 305-373, 1857; "The Geology of Bolivia and Southern Peru," Journ. Geol. Soc. xvii. pp. 7-65, 1861; "The Mineralogy of Chile," Phil. Mag. 1865; "Researches in British Mineralogy," Phil. Mag., 1867-1868. His observations on the geology of South America were given in a masterly essay, and these and subsequent researches threw much light on igneous and metamorphic phenomena and on the resulting changes in rock-formations. He also contributed important articles on chemical geology to the Chemical News and Geological Magazine (1857 and 1868). In England he was a pioneer in microscopic petrology. He was elected F.R.S. in 1858. He died in London on the 5th of December 1870.

FORBES, DUNCAN, of Cullooden (1685-1747). Scottish statesman, was born at Bunchrew or at Cullooden near Inverness on the 10th of November 1685. After he had completed his studies at the universities of Edinburgh and Leiden, he was admitted advocate at the Scottish bar in 1709. His own talents and the influence of the Argyll family secured his rapid advancement, which was still further helped by his loyalty to the Hanoverian cause at the period of the rebellion in 1715. In 1722 Forbes was returned member for Inverness, and in 1725 he succeeded Alexander Arnacloney as advocate. He inherited the patrimonial estates on the death of his brother in 1734, and in 1737 he attained to the highest legal honours in Scotland, being made lord president of the court of session. As lord advocate, he had laboured to improve the legislation and revenue of the country, to extend trade and encourage manufactures, and no less to render the government popular and respected in Scotland. In the proceedings which followed the memorable Porteous mob, for example, when the government brought in a bill for disfracing the lord provost of Edinburgh, for fixing the corporation, and for abolishing the town-guard and city-gate, Forbes both spoke and voted against the measure as an unwarranted outrage on the national feeling. As lord president also he carried out some useful legal reforms; and his term of office was characterized by quick and impartial administration of the law.

The rebellion of 1745 found him at his post, and it tried all his patriotism. Some years before (1738) he had repeatedly and earnestly urged upon the government the expediency of embodying Highland regiments, putting them under the command of colonels, and whose loyalty could be relied upon, but offering them with the native chieftains and cadets of old families in the north. "If government," said he, "pre-engages the Highlanders in the manner I propose, they will not only serve well against the enemy abroad, but will be hostages for the good behaviour of their relations at home; and I am persuaded that it will be absolutely impossible to raise a rebellion in the Highlands." In 1739, with Sir Robert Walpole's approval, the original (1730) six companies (locally enlisted) of the Black Watch were formed into the famous "Fourth-sonly regiment of the line. The object of this bill, after repeated solicitations that his credit might be injured, is an error; it rests really with Forbes and his friend Lord Islay, afterwards 3rd duke of Argyll (see the Autobiography of the 8th duke of Argyll, vol. i. p. 8 sq., 1906). On the first rumour of the Jacobite rising Forbes hastened to Inverness, and through his personal influence with the chiefs of Maconald and Macleod, those two powerful western clans were prevented from taking the field for Charles Edward; the town itself also he kept loyal and well protected at the commencement of the struggle, and many of the neighbouring proprietors were won over by his persuasions. His correspondence with Lord Lovat, published in the Culloden papers, affords a fine illustration of his character, in which the firmness of loyal principle and duty is found blended with neighbourly kindness and consideration. But at this critical juncture of affairs, the apathy of the government interfered considerably with the success of his negotiations. Advances of arms and money arrived too late, and though Forbes employed all his own means and what money he could borrow on his personal security, his resources were quite inadequate to the emergency. It is doubtful whether these advances were ever fully repaid. Part was doted out, after repeated solicitations that his credit might be maintained in the country; but it is evident he had fallen into disgrace in consequence of his humane exertions to mitigate the impolitic severities inflicted upon his countrymen after their disastrous defeat at Culloden. The ingratitude of the government, and the many distressing circumstances connected with the insurrection, sunk deep into the mind of Forbes. He never fairly rallied from the depression thus caused, and after a period of declining health he died on the 10th of December 1747.

Forbes was a patriot without ostentation or pretence, a true Scotsman with no narrow prejudices, an accomplished and even erudite scholar without pedantry, a man of genuine piety without asceticism or intolerance. His country long felt his influence through her reviving arts and institutions; and the example of such a character in that coarse and venal age, and among a people distracted by faction, political strife, and national anti-pathies, while it was invaluable to his contemporaries in a man of high position, is entitled to the lasting gratitude and veneration of his countrymen. In his intervals of leisure he cultivated with some success the study of philosophy, theology and biblical criticism. He is said to have been a diligent reader of the Hebrew Bible. His published writings, some of them of importance, include—A Letter to a Bishop, concerning some Important Discoveries in Philosophy and Theology (1732); Some Thoughts concerning Religion, natural and revealed, and the Manner of Understanding Revelation (1733); and Reflections on Incredulity (2nd ed., 1750).

His correspondence was collected and published in 1815, and a memoir of him (from the family papers) was written by Mr Hill Burton, and published along with a Life of Lord Lovat, in 1847. His statue by Roubillac stands in the Parliament House, Edinburgh.
FOBES, E.—FOBES, J. D.

FOBES, EDWARD (1815-1854), British naturalist, was born at Douglas, in the Isle of Man, on the 12th of February 1815. While still a child, when not engaged in reading, or in the writing of verses and drawing of caricatures, he occupied himself with the collecting of insects, shells, mineral, fossils, plants and other natural history objects. From his fifth to his eleventh year, delicacy of health prevailed, and he was educated at an Eton school. But in 1828 he became a day scholar at Athole House Academy in Douglas. In June 1831 he left the Isle of Man for London, where he studied drawing. In October, however, having given up all idea of making painting his profession, he returned home; and in the following month he matriculated as a student of medicine in the university of Edinburgh. His vacation in 1832 he spent in diligent work on the natural history of the Isle of Man. In 1833 he made a tour in Norway, the botanical results of which were published in London’s Magazine of Natural History for 1835-1836. When in the summer of 1834 he devoted much time to dredging in the Irish Sea; and in the succeeding year he travelled in France, Switzerland and Germany.

Born a naturalist, and having no relish for the practical duties of a surgeon, Forbes in the spring of 1836 abandoned the idea of taking a medical degree, resolving to devote himself to science and literature. The winter of 1836-1837 found him at Paris, where he attended the lectures at the Jardin des Plantes on natural history, comparative anatomy, geology and mineralogy. Leaving Paris in April 1837, he went to Algiers, and there obtained materials for a paper which was published in the Annals of Natural History, vol. ii. p. 250. In the same year he was registered at Edinburgh as a student of literature; and in 1838 appeared his first volume, Malacologia Monensis, a synopsis of the species of Manx Mollusca. During the summer of 1838 he visited Styria and Carniola, and made extensive botanical collections. In the following autumn he read before the British Association at Newcastle a paper on the distribution of terrestrial Pulmoniferata in Europe, and was commissioned to prepare a similar report with reference to the British Isles. In 1841 was published his History of Star-fishes, embodying extensive observations and containing 120 illustrations, inclusive of humorous tail-pieces, all designed by the author. On the 17th of April of the same year Forbes, accompanied by his friend William Thompson, joined at Malta H.M. surveying ship “Reacon,” to which he had been appointed naturalist by her commander Captain Graves. From that date until October 1842 he was employed in investigating the botany, zoology and geology of the Mediterranean region. The results of these researches were made known in his “Report on the Mollusca and Radiata of the Aegean Sea,” published in 1843 in the Annals of Natural History, vol. ii. p. 250. In conjunction with Lieut. (afterwards Admiral) T. A. B. Spratt in 1847. In the former treatise he discussed the influence of climate and of the nature and depth of the sea bottom upon marine life, and divided the Aegean into eight biological zones; his conclusions with respect to bathymetrical distribution, however, have naturally been modified to a considerable extent by the more recent explorations of the deep seas.

Towards the end of the year 1843 Forbes, whom family misfortunes had now thrown upon his own resources, sought and obtained the curatorship of the Geological Society of London. To the duties of that post he added in 1843 those of the professorship of botany at King’s College. In November 1844 he resigned the curatorship of the Geological Society, and became palaeontologist to the Geological Survey of Great Britain. Two years later he published in the Memoirs of the Geological Survey, i. 336, his important essay “On the Connexion between the distribution of the existing Fauna and Flora of the British Isles, and the Geological Changes which have affected their Origin, especially during the epoch of the Northern Drift.” It is therein pointed out that, in accordance with the theory of their origin from various specific centres, the plants of Great Britain may be divided into five well-marked groups: the W. and S.W. Irish, represented in the N. of Spain, the E.E. Irish and S.W. English, related to the flora of the Channel Islands and the neighbouring part of France; the S.E. English, characterized by species occurring on the opposite French coast; a group peculiar to mountain summits, Scandinavian in type; and, lastly, a general or Germanic flora. From a variety of arguments the conclusion is drawn that the greater part of the terrestrial animals and flowering plants of the British Islands migrated thitherward, over continuous land, at three distinct periods, before, during and after the glacial epoch. On this subject Forbes’s brilliant generalizations are now regarded as only partially true (see C. Reid’s Origin of the British Flora, 1899). In the autumn of 1848 Forbes married the daughter of General Sir C. Ashworth; and in the same year was published his Monograph of the British Naked-eyed Mollusca (Ray Society). The year 1851 witnessed the removal of the collections of the Geological Survey from Craig’s Court to the museum in Jermyn Street, and the appointment of Forbes as professor of natural history to the Royal School of Mines just established in conjunction therewith. In 1852 was published the fourth and concluding volume of Forbes and S. Hanley’s History of British Mollusca; also his Monograph of the Echinodermata of the British Tertiaries (Palaeontographical Soc.).

In 1853 Forbes held the presidency of the Geological Society of London, and in the following year he obtained the fulfillment of a long-desired wish in his appointment to the professorship of natural history in the university of Edinburgh, vacant by the death of R. Jameson, his former teacher. Since his return to Scotland he continued his investigations into the history of fossils, frequent lectures, and incessant literary work, including the preparation of his palaeontological memoirs, had precluded Forbes from giving that attention to the natural history pursuits of his earlier life which he had earnestly desired. It seemed that at length he was to find leisure to reduce to order his stores of biological information. He lectured at Edinburgh, in the summer session of 1854, and in September of that year he occupied the post of president of the geological section at the Liverpool meeting of the British Association. But he did not live to witness the completion of his ambitious purpose. He died after a short illness at his home, 89 John Street, Edinburgh, on the 26th of November 1854.

See Literary Gazette (November 25, 1854); Edinburgh New Philosophical Journal (New Ser.), (1855); Quarterly Review, Geol. Soc. (May 1855); G. Wilson and A. Geikie, Memoirs of Edward Forbes (1861), in which, pp. 575-583, is given a list of Forbes’s writings. See also Literary Papers, edited by Lovell Reeve (1855). The following works were issued posthumously: “On the Tertiary Fluvioline Formation of the Isle of Wight” (Geol. Survey), edited by R. A. C. Godwin-Austen (1855); “The Natural History of the European Seas,” edited and continued by R. A. C. Godwin-Austen (1859).

FOBES, JAMES DAVID (1809-1868), Scottish physicist, was the fourth son of Sir William Forbes, 7th baronet of Pitsligo, and was born at Edinburgh on the 20th of April 1809. He entered the university of Edinburgh in 1825, and soon afterwards began to contribute papers to the Edinburgh Philosophical Journal anonymously under the signature “Δ.” At the age of nineteen he became a fellow of the Royal Society of Edinburgh, and in 1832 he was elected to the Royal Society of London. A year later he was appointed professor of natural philosophy in Edinburgh University. For John Clerk of Eldin’s professorship of the subject he was recommended by Sir David Brewster, and during his tenure of that office, which he did not give up till 1860, he not only proved himself an active and efficient teacher, but also did much to improve the internal conditions of the university. In 1859 he was appointed successor to Brewster in the principalship of the United College of St Andrews, a position which he held until his death at Clifton on the 31st of December 1868.

As a scientific investigator he is best known for his researches on heat and on glaciers. Between 1836 and 1844 he published in the Trans. Roy. Soc. Ed., four series of “Researches on Heat,” in the course of which he described the polarization of heat by tourmaline, by transmission through a bundle of thin mica plates inclined to the transmitted ray, and by reflection from the multiplied surfaces of a pile of mica plates placed at the polarizing angle, and also its circular polarization by two internal
reflections in rhombs of rock-salt. His work won him the Rumford medal of the Royal Society in 1835, and in 1843 he received its Royal medal for a paper on the "Transparency of the Atmosphere and the Laws of Extinction of the Sun's Rays passing through it." In 1846 he began experiments on the temperature of the earth at different places and times. In 1878 E. Forbin published the results of his experiments. He yielded determinations of the thermal conductivity of trap-tufa, sandstone and pure loose sand. Towards the end of his life he was occupied with experimental inquiries into the laws of the conduction of heat in bars, and his last piece of work was to show that the thermal conductivity of iron diminishes with increase of temperature. His attention was directed to the question of the flow of glaciers in 1840 when he met Louis Agassiz at the Glasgow meeting of the British Association, and in subsequent years he made several visits to Switzerland and also to Norway for the sole purpose of obtaining accurate data. His observations led him to the view that a glacier is an imperfect fluid or a viscous body which is urged down slopes of a certain inclination by the mutual pressure of its parts, and involved him in some controversy with Tyndall and others both as to priority and to scientific principle. Forbes was also interested in geology, and published memoirs on the thermal springs of the Pyrenees, on the extinct volcanoes of the Vivarais ( Ardèche), on the geology of the Cucullini and Eildon hills, &c. In addition to about 150 scientific papers, he wrote Travels through the Alps of Savoy and Other Parts of the Female Country, with Observations on the Phenomena of Glaciers and other singularities of the climate (1833); Occasional Papers on the Theory of Glaciers (1850); A Tour of Mont Blanc and Monte Rosa (1855). He was also the author of the "Dissertation on the Progress of Mathematical and Physical Science," published in the 8th edition of the Encyclopaedia Britannica.

FORBES, SIR JOHN (1857-1861), British physician, was born at Cuthbert's Band, in 1737. He attended the grammar school at Aberdeen, and afterwards entered Marischal College. After serving for nine years as a surgeon in the navy, he graduated M.D. at Edinburgh in 1817, and then began to practise in London, whence he removed to Chichester in 1822. He took up his residence in London in 1849, and in the following year was appointed physician to the royal household. He was knighted in 1853, and died on the 15th of November 1861 at Whitchurch in Berkshire. Sir John Forbes was better known as an author and editor than as a practical physician. His works include: On the Use of the Stethoscope (1817) and on the Use of the Thermometer in the Diagnosis of Diseases of the Chest (1842); Illustrations of Modern Mesmerism (1831); A Physician's Holiday (1st ed., 1849); Memorandum made in Ireland in the Autumn of 1852 (2 vols., 1853); Sightseeing in Germany and the Tyrol in the Autumn of 1855 (1856). He was joint editor with A. Tweedie and J. Conolly of The Cyclopaedia of Practical Medicine (4 vols., 1833-1835); and in 1836 he founded The British and Foreign Medical Review, which, after a period of prosperity, involved its editor in pecuniary losses, and was discontinued in 1847, partly in consequence of the advocacy in its later numbers of doctrines obnoxious to the profession.

FORBES, a municipal town of Ashburnham county, New South Wales, Australia, 280 m. W. by N. from Sydney, on the Lachlan river, and with a station on the Great Western railway. Pop. (1901) 4313. Its importance as a commercial centre is due to its advantageous position between the northern and southern markets. It has steam-sawing and flour-mills, breweries and wool-scouring establishments; while the surrounding country produces good quantities of cereals, lucerne, wine and fruit.

FORBES-ROBERTSON, JOHNSTON (1859-1863), English actor, was the son of John Forbes-Robertson of Aberdeen, an art critic. He was educated at Charterhouse, and studied at the Royal Academy schools with a view to becoming a painter. But though he kept up his interest in that art, in 1874 he turned to the theatre, making his first appearance in London as Chastelard, in "Mary, Queen of Scots." He studied under Samuel Phelps, from whom he learnt the traditions of the tragic stage. He played with the Bancrofts and with John Hare, supported Miss Mary Anderson in both England and America, and also acted at different times with Sir Henry Irving. His refined and artistic style, and beautiful voice were so conspicuous that he was marked as a man on the English stage, and in Pinero's "The Prodigal Son." His Garrick theatre (1889), under Hare's management, he establishes his position as one of the most individual of London actors. In 1895 he started under his own management at the Lyceum with Mrs Patrick Campbell, producing "Romeo and Juliet," "Hamlet," "Macbeth," and also some modern plays; his impersonation as Hamlet was especially fine, and his capacity as a romantic actor was shown to great advantage also in John Davidson's "For the Crown" and in Maeterlinck's "Pelléas et Mélisande." In 1900 he married the actress Ada Elliott, with whom, as his leading lady, he appeared at various theatres, producing in subsequent years "The Light that Failed," Madeleine Lucette Riley's "Mice and Men," and G. Bernard Shaw's "Cesar and Cleopatra," Jerome K. Jerome's "Passing of the Third Floor Back," &c. His brothers, John Robertson (b. 1858) and Norman Forbes (b. 1859), had also been well-known actors from about 1878 onwards.

FORBIN, CLAUDE DE (1656-1733), French naval commander, was born in Provence, of a family of high standing, in 1656. His father died and left him a very large fortune. When he was 13, he was made a page in the French navy, serving his first campaign in 1675. Forbin accompanied the chevalier de Chaumont with the rank of major. When Chaumont returned to France, Forbin was induced to remain in the service of the Siamese king, and accepted, though with much reluctance, the posts of grand admiral, general of all the king's armies and governor of Bangkok. His position, however, was soon made untenable by the jealousy and intrigues of the minister Phaulcon; and at the end of two years he left Siam, reaching France in 1688. He was afterwards fully engaged in active service, first with Jean Bart in the war against England, and then with the English fleet in the Baltic. He was next sent to Plymouth. They succeeded in making their escape and were soon serving their country again. Forbin was wounded at the battle of La Hogue, and greatly distinguished himself at the battle of Lagos. He served under D'Estrées at the taking of Barcelona, and was sent ambassador to Algiers, and in 1702 took a brilliant part in the Mediterranean in the War of the Spanish Succession. In 1706 he took command of a squadron at Dunkirk, and captured many valuable prizes from the Dutch and the English. In 1708 he was entrusted with the command of the squadron which was to convey the Pretender to Scotland; but so effectually were the coasts guarded by Byng that the expedition failed, and returned to Dunkirk. Forbin was now beginning to be weighed down with the infirmities of age and the toils of service, and in 1710 he retired to a country house near Marseilles. There he spent part of his time in writing his memoirs, published in 1730, which are full of interest and are written in a graphic and attractive style. Forbin died on the 4th of March 1733.

FORCELLINI, EGIDIO (1688-1768), Italian philologist, was born at Fener in the district of Treviso and belonged to a very poor family. He went to the seminary at Padua in 1704, studied under Facciolati, and in due course attained to the priesthood. From 1724 to 1731 he held the office of rector of the seminary at Ceneda, and from 1731 to 1765 that of father confessor in the seminary of Padua. The remaining years of his life were
mainly spent in his native village. He died at Padua in 1768 before the completion of the great work on which he had long co-operated with Faccioli. This was the vast Latin Lexicon (see FACCIOt), which has formed the basis of all similar works that have since been published. He was engaged with his Herculean task for nearly 35 years, and the transcription of the manuscript by Luigi Violato occupied eight years more.

FORCHHAMMER, JOHANN GEORG (1794–1865), Danish mineralogist and geologist, was born at Husum, Schleswig, on the 24th of July 1794, and died at Copenhagen on the 14th of December 1865. After studying at Copenhagen and Copenhagen University he became lecturer at Lauteritz Eschmar in their mineralogical exploration of Bornholm, and took a considerable share in the labours of the expedition. In 1820 he obtained his doctor's degree by a chemical treatise De mangano, and immediately after set out on a journey through England, Scotland, and the Faeroe Islands. In 1823 he was appointed lecturer at Copenhagen University on chemistry and mineralogy; in 1829 he obtained a similar post in the newly established polytechnic school; and in 1831 he was appointed professor of mineralogy in the university, and in 1848 became curator of the gallery of minerals of this institution. From 1835 to 1843 he made many contributions to the geological survey of Denmark. On the death of H. C. Oersted in 1851, he succeeded him as director of the polytechnic school and secretary of the Academy of Sciences. In 1850 he began with J. Steenstrup and Worsaae various anthropological publications which gained a high reputation. As a public instructor Forchhammer held a high place and contributed potently to the progress of his favourite studies in his native country. He interested himself in such practical questions as the introduction of gas into Copenhagen, the construction of the fire-brigades at Rosenborg and the boring of artesian wells.

Among his more important works are:—Loebefog i de enkelte Radicalsers Chemi (1842); Danmarks geognostiske Forhold (1853); Om de Bornholmiske Kullformationer (1860); Bild myere Kråd's Dan- mandskab (1851); Til Skildringen af ejer (1859); Geognostiske Forhold (1858). A list of his contributions to scientific periodicals, Danish, English, and German, will be found in the Catalogue of Scientific Papers published by the Royal Society of London. One of the most interesting and most recent is "On the Constitution of Sea Water at Different Depths and in Different Latitudes," in the Proceedings of the Roy. Soc. xii. (1862–1863).

FORCHHAMMER, PETER WILHELM (1801–1894), German classical archaeologist, was born at Husum in Schleswig on the 23rd of October 1801. He was educated at the Lübeck gymnasium and the university of Kiel, with which he was connected for nearly 65 years. In 1830–1834 and 1838–1840 he travelled in Italy, Greece, Asia Minor and Egypt. In 1843 he was appointed professor of philology at Kiel and director of the archaeological museum founded by himself in co-operation with Otto Jahn. He died on the 8th of January 1894. Forchhammer was a democrat in the best sense of the word, and from 1871 to 1873 represented the progressive party of Schleswig-Holstein in the German Reichstag. His published works deal chiefly with topography and ancient mythology. His travels had convinced him that a full and comprehensive knowledge of classical antiquity only could be acquired by a thorough acquaintance with Greek and Roman monuments and works of art, and a detailed examination of the topographical and climatic conditions of the chief localities of the ancient world. These principles are illustrated in his Hellenika. Griechenland. Im Neuen das Ate (1837), which contains his theory of the origin and explanation of the Greek myths, which he never abandoned, in spite of the attacks to which it was submitted. According to him, the myths arose from definite local (especially aquatic and atmospheric) phenomena, and represented the annually recurring processes of nature as the acts of gods and heroes; thus, in Achill (1853), the Trojan War is the winter conflict of the elements in that district. Other similar short treatises are:—Die Gründung Roms (1868); Dädakos (1873), on the language of the myths and mythical buildings;—Die Wanderungen der Inachostochter Io (1880); Prometomna zur Mythology als Wissenschaft und Lehre;—The Krischne (1891). Amongst his topographical works mention may be made of:—Topographie von Athen (1841); Beschreibung der Ebene von Troja (1850), a commentary on a map of the locality executed by T. A. Spratt (see Journal of the Royal Geographical Society, xii., 1842); Topographia The- barum Heptaplarum (1854); Erklärung der IIias (1884), on the basis of the topographical and physical peculiarities of the plain of Troy. His Demokratenbüchlein (1849), in the main a discussion of the Aristotelian theory of the state, and Die Athener und Seleukides (1837), in which, contrary to the almost universal opinion, he upheld the procedure of the Athenians as perfectly legal and their verdict as a perfectly just one, also deserves notice.

For a full list of his works see the obituary notice by E. Alberti in C. Burian's Biographisches Jahrbuch für Allertumskunde, xx. (1897); also J. Sass in Allgemeine deutsche Biographie, and A. Hoeck and L. Jancke, P. W. Fohr, and F. H. Knaak: Biographisches Lexikon der Deutschen Literatur (1895).

FORTHHEIM, a town of Germany, in the kingdom of Bavaria, near the confluence of the Wiesent and the Regnitz, 16 m. S.S.E. of Bamberg. Pop. (1905) 8417. It has four Roman Catholic churches, including the Gothic Collegiate church and a Protestant church. Among the other public buildings are the progymnasium and an orphanage. The industries of the town include spinning and weaving, bleaching and dyeing, bone and leather trades, brewing and paper-making. The spacious chateau occupies the site of the Carolingian palace which was destroyed in 1248.

Forchheim is of very early origin, having been the residence of the Carolingian sovereigns, including Charlemagne, in the 9th century. Consequently many diets were held here, and here also Conrad I. and Louis the Child were chosen German kings. The town was given by the emperor Henry II. in 1007 to the bishopric of Bamberg, and, except for a short period during the 11th century, it remained in the possession of the bishops until 1802, when it was ceded to Bavaria. In August 1796 a battle took place near Forchheim between the French and the Austrians. The fortifications of the town were dismantled in 1838. See Hübsch, Chronik der Stadt Forchheim (Nürnberg, 1867).

FORD, EDWARD ONSLOW (1852–1901), English sculptor, was born in London. He received some education as a painter in Antwerp and as a sculptor in Munich under Professor Wagn- Müller, but was mainly self-taught. His first contribution to the Royal Academy, in 1875, was a bust of his wife, and in portraiture he may be said to have achieved his greatest success. His busts are always extremely refined and show his sitters at their best. Those (in bronze) of his fellow-artists Arthur Hacker (1894), Briton Riviere and Sir W. Q. Orchardson (1895), Sir L. Alma-Tadema (1896), Sir Hubert von Herkomer and Sir John Millais (1867), and of A. J. Balfour are all striking likenesses, and are equalled by that in marble of Sir Frederick Bramwell (for the Royal Institution) and by many more. He gained the open competition for the statue of Sir Rowland Hill, erected in 1862 outside the Royal Exchange, and followed it in 1883 with "Henry Irving as Hamlet," now in the Guildhall art gallery. This seated statue, good as it is, was soon surpassed by those of Dr Dale (1883, in the city museum, Birmingham) and Professor Huxley (1900), but the colossal memorial statue of Queen Victoria (1901), for Manchester, was less successful. The standing statue of W. E. Gladstone (1894, for the City Liberal Club, London) is to be regarded as one of Ford's better portrait works. The colossal "General Charles Gordon," eamel-mounted, for Chatham, "Lord Strathnairn," an equestrian group for Knightsbridge, and the "Maharajah of Mysore" (1906) comprise his larger works of the kind. A beautiful nude recumbent statue of Shelley (1892) upon a cleverly-designed base, which is not quite impeccable from the point of view of artistic taste, is at University College, Oxford, and a simplified version was presented by him to be set up on the shore of Viareggio, where the poet's body was washed up. Ford's ideal work has great charm and daintiness; his statue "Folly" (1886) was bought by the trustees of the Chantrey Fund, and was followed by other statues or statuettes of a similar order: "Peace" (1890), which secured his election as an associate of the Royal Academy, "Echo" (1895), on which he was elected full member, "The
FORD, J.

641

Egyptian Singer" (1889), "Applause" (1893), "Glory to the Dead" (1901) and "Snowdrift" (1902). Ford's influence on the younger generation of sculptors was considerable and of good effect. His charming disposition rendered him extremely popular, and when he died a monument was erected to his memory (C. Lucchesi, sculptor, J. W. Simpson, architect) in St. John's Wood, near to where he dwelt.

Joseph M. H. Spielmann, British Sculpture and Sculptors of To-Day (London, 1901).

FORD, JOHN (1586-c.1640), English dramatist, was baptized on the 17th of April 1586 at Ilsington in north Devon. He came of a good family; his father was in the commission of the peace and his mother was a sister of Sir John Popham, successively attorney-general and lord chief justice. The name of John Ford appears in the university register of Oxford as matriculating at Exeter College in 1601. Like a cousin and namesake (to whom, with other members of the society of Gray's Inn, he dedicated his play of The Lover's Melancholy), the future dramatist entered the profession of the law, being admitted of the Middle Temple in 1602; but he seems never to have been called to the bar.

Four years afterwards he made his first appearance as an author with an elegy called Fane's Memorial, or the Earl of Devonshire deceased, and dedicated to the widow of the earl (Charles Blount, Lord Mountjoy, "coronized," to use Ford's expression, by King James in 1603 for his services in Ireland)—a lady who would have been no unifying heroine for one of his own tragedies of lawless passion, the famous Penelope, formerly Lady Rich. This panegyric, which is accompanied by a sonnet of epitaphs, was included in a series of feuds, extravagances, was, as the author declares, written "unfed'd;" it shows that Ford sympathized, as Shakespeare himself is supposed to have done, with the "awkward fate" of the countess's brother, the earl of Essex. Who the "flint-hearted Lycia" may be, to whom the poet seems to allude as his own disdainful mistress, is unknown; indeed, the record of Ford's private life is little better than a blank. To judge, however, from the dedications, prologues and epilogues of his various plays, he seems to have enjoyed the patronage of the earl, afterwards duke, of Newcastle, "himsel" a muse," after a fashion, and Lord Craven, the supposed husband of the ex-queen of Bohemia. Ford's tract of Honor Triumphant, or the Peers Challenge (printed 1606 and reprinted by the Shakespeare Society with the Line of Life, in 1843), and the simultaneously published verses The Monarches Meeting, or the King of Denmarkes Welcome into England, exhibit him as occasionally meeting the festive demands of court and nobility; and a kind of moral essay by him, entitled A Line of Life (printed 1620), which contains references to Raleigh, ends with a climax of fulsome praise to the address of King James I. Yet at least one of Ford's plays was printed in the dramatic protest against the absolute system of government generally accepted by the dramatists of the early Stuart reigns. Of his relations with his brother-authors little is known; it was natural that he should exchange complimentary verses with James Shirley, and that he should join in the chorus of laments over the death of Ben Jonson. It is more interesting to notice an epigram in honour of Ford by Richard Crashaw, morbidly passionate in one direction as Ford was in another. The lines run:

"Thou chest'st us, Ford: mak'st one seem two by art:
What is Love's sacrifice but the Broken Heart?"

It has been concluded that in the latter part of his life he gratified the tendency to seclusion for which he was ridiculed in The Time Poets (Choice Droullery, 1656) by withdrawing from business and from literary life in London, to his native place; but nothing is known as to the date of his death. His career as a dramatist very probably began by collaboration with other authors. With Thomas Dekker he wrote The Fairy Knight and The Briseis Merchant (licensed in 1624, but both unpublished), with John Webster A Late Murdrer of the Sonne upon the Mother (licensed in 1624). A play entitled An ill Beginning has a good End, brought on the stage as early as 1613 and attributed to Ford, was (if his) his earliest acted play; whether Sir Thomas Overbury's Life and untimely Death (1615) was a play is extremely doubtful; some lines of ingrant regret by Ford on the same subject are still preserved. He is also said to have written, at dates unknown, The London Merchant (which, however, was an earlier name for Beaumont and Fletcher's Knight of the Burning Pestle) and The Royal Combat; a tragedy by him, Beauty in a Trance, was entered in the Stationers' Register in 1653, but never printed. These three (or four) among those destroyed by Washbourne's Miser; or The Queen, or the Excellence of the Sea, a play of invented passion, containing some fine sensuous lines, printed in 1653 by Alexander Singhe for private performance, has been recently edited by W. Bang (Materialien zur Kunde d. älteren engl. Dramas, 13, Louvain, 1906), and is by him on internal evidence confidently claimed as Ford's. Of the plays by Ford preserved to us the dates span little more than a decade—the earliest, The Lover's Melancholy, having been acted in 1628 and printed in 1629, the latest, The Lady's Trial, acted in 1638 and printed in 1639.

When writing The Lover's Melancholy, it would seem that Ford had not yet become fully aware of the bent of his own dramatic genius, although he was already master of his powers of poetic expression. He was attracted towards domestic tragedy by an irresistible desire to sound the depths of abnormal conflicts between passion and circumstances, to romantic comedy by a strong though not widely varied imaginative faculty, and by a delusion that he was possessed of abundant comic humour. In his next two works, undeniably those most characteristicly expressive of his peculiar strength, 'Tis Pity she's a Whore (acted c. 1636) and The Broken Heart (acted c. 1629), the latter printed in 1633 with the anagram of his name Fide Honor, he had found horrible situations which required dramatic explanation by intensely powerful motives. Ford by no means stood alone among English dramatists in his love of abnormal subjects; but few were so capable of treating them sympathetically, and yet without that recklessness grossness or extravagance of expression which renders the morally repulsive aesthetically intolerable, or converts the horrible into the grotesque. For in Ford's genius there was real refinement, except when the "supra-sensually sensual" impulse or the humbler self-delusion referred to came into play. In a third tragedy, Love's Sacrifice (acted c. 1639; printed in 1633), he again worked on similar materials; but this time he unfortunately essayed to base the interest of his plot upon an unendurably unnatural possibility—doing homage to virtue after a fashion which is in itself an insult. In Perkin Warbeck (printed 1614; probably acted a year later) he chose an historical subject of great dramatic promise and psychological interest, and sought to emulate the glory of the great series of Shakespeare's national histories. The effort is one of the most laudable, as it was by no means one of the least difficult. The Witch of Edmonton (printed 1635, but probably acted about 1621), in which we see Ford as a joint writer with Dekker and Rowley of one of the most powerful domestic dramas of the English or any other stage.

A few notes may be added on some of the more remarkable of the plays enumerated. A wholly baseless anecdote, concocted into a piping copy by Thomas Delius of A True Report of the Famous Portrach of the Miserable Melancholy was stolen by Ford from Shakespeare's papers. Undoubtedly, the madness of the hero of this play of Ford's occasionally recalls Hamlet, while the heroine is one of the many, and at the same time one of the most pleasing, parallels to Viola. But neither of them is a copy, as Friar Bonaventura in Ford's second play may be said to be a copy of Friar Lawrence, whose kindly pliability he disagreeably exaggerates, or as D'Avolos in Love's Sacrifice is clearly modelled on Iago. The plot of The Lover's Melancholy, which is ineffective because it leaves no room for suspense in the mind of
the reader, seems original; in the dialogue, on the other hand, a justly famous passage in Act i. (the scene in which the nightriders’ death is translated from Strada; while the scheme of the tedious interlude exhibiting the various forms of madness is awfully taken, together with sundry comments, from Burton’s Anatomy of Melancholy). Already the presentation of this piece, as it stands, has an attractive Schiller, who, however, seems to have abandoned it in the interest of the similar theme of the Russian Demetrius. Had Shakespeare treated it, he would hardly have contented himself with investing the whole drama with the dignity and the pathos of a political tragedy. The pretense of the play—for it is hardly possible to speak of a personage as a character when the clue to his conduct is intentionally withheld. Nor could Shakespeare, it appears, bring to bear upon him, with greater variety and distinctiveness the dramatic features in Henry VII., whom Ford, with sufficient distinction to give some degree of individuality to the character, but still with a tenderness of touch which would have been unknown to Shakespeare, could not but have reprinted under the title of the Tudor age. The play is, however, founded on Bacon’s Life, of which the text is used by Ford with admirable discretion, and on Samuel Gainsford’s True and Wonderful History of Perkin Warbeck (1618). The subject of the play was no doubt suggested by the case of the reported witch, Elizabeth Sawyer, who was executed in 1621. Swinburne agrees with Gifford in thinking Ford the author of the whole of the play, and that he had been engaged in reconstructing it. It is difficult to believe that there is no more admirable exposition of a play on the English stage.

The Witch of Edmonton was attributed by its publisher to William Rowley, Dekker, Ford, “&c.”, but the body of the play has been generally held to be ascribed to Ford. This attribution has been suggested by the report of the witch, Elizabeth Sawyer, who was executed in 1621. Swinburne agrees with Gifford in thinking Ford the author of the whole of the play, and that he had been engaged in reconstructing it. It is difficult to believe that there is no more admirable exposition of a play on the English stage.

Supposing Dekker to be chiefly responsible for the scenes dealing with the unfortunate old woman, and Gifford to have done the work of the first three acts, and Gifford to have written the whole of the comic part, but that the last two acts are mainly Ford’s. If so, he is the author of the rather forced occasional tribute on the accession of King Charles I., of which the last act largely consists. This mask, which furnished abundant opportunities for the decorators, musicians and dancers, in showing forth the seasons and their delights, and for successive masques, ‘The Dance of the Hours’ had a bright grandchild of the Sun, is said to have been very popular. It is at the same time commonplace enough in conception; but such a combination in one piece was not of course to be expected, Loly being respectively laid under contribution in the course of the dialogue, and in one of the incidental lyrics.

Ford owes his position among English dramatists to the intensity of his passion, in particular scenes and passages where the character, the author and the reader are alike lost in the situation and in the sentiment evoked by it; and this gift is a supreme dramatic gift. But his plays—with the exception of The Witch of Edmonton, in which he doubtless had a double share—too often disturb the mind like a bad dream which ends as an unsolved dissonance; and this defect is a supreme dramatic defect. It is not the rigid or the stolid who have the most reason to complain of the insufficiency of tragic poetry such as Ford’s; nor is it that morality only which, as Jowett says in The Broken Heart, “is formed of books and school-traditions,” which has a right to protest against the final effect of the most powerful creations of his genius. There is a morality which both poets hold to be desirable.

Keeps the soul in tune,
At whose sweet sound all our actions dance.

The sickness of a mind
Broken with griefs.

Of that morality—or of that deference to the binding power within man and the ruling power above him—tragedy is the true exponent, even when it illustrates by contrasts; but the tragic poet who merely places the problem before us, and bids us stand aghast with him at its cruelty, is not to be reckoned among the great masters of a divine art.
and he found himself junior to Eyre Coote, his old subaltern in the 93rd Foot. Nevertheless he continued to assist Clive, and on the 25th of November 1759 won a success comparable to Condore at Chinsurah (or Biderra) against the Dutch. A year later he at last received his commission, but was still opposed by a faction of the directors which supported Coote. Clive himself warmly supported Forde in these quarrels. In 1769, with Vansittart and Scarfaton, Colonel Forde was sent out with full powers to investigate every detail of Indian administration. Their ship was never heard of after leaving the Cape of Good Hope on the 27th of December.

Monographs on Condore, Masulipatam and Chinsurah will be found in Malleson's Descriptive Battles of India.

FORDHAM, formerly a village of Westchester county, New York, U.S.A., and now a part of New York City. It lies on the mainland, along the eastern bank of the Harlem river, E, of the northern end of Manhattan Island. It is the seat of Fordham University (Roman Catholic), founded in 1841 as St John's College, and since 1846 conducted by the Society of Jesus. In 1907 the institution was rechartered as Fordham University, and includes St. John's College high school and grammar school, St. John's College, the Fordham University School of Law (all in Fordham), and the Fordham University law school (42 Broadway, New York City). In 1907-1908 the university had 96 instructors and (exclusive of 364 students in the high school) 236 students, of whom 105 were in St. John's College, 31 in the medical school, and 100 in the law school. In Fordham still stands the house in which Edgar Allan Poe lived from 1844 to 1849 and in which he wrote "Annabel Lee," "Ulalume," etc.

The hamlet of Fordham was established in 1669 by Jan Arcer (a Dutchman, who called himself "John Archer" after coming to America), who in that year received permission from Francis Lovelace, colonial governor of New York, to settle sixteen families on the mainland close by a fording-place of the Spuyten Duyvil Creek, near where that stream enters the Harlem river. Between 1655 and 1671 Archer bought from the Indians the tract of land lying between Spuyten Duyvil Creek and the Harlem river on the east and the Bronx river on the west, and extending from the hamlet of Fordham to what is now High Bridge. In 1671 Governor Lovelace erected this tract into the manor of Fordham. In 1846 it was included with Morrisania and Bowery in the present city of Fordham University. The new town of Yonkers was erected into the township of Kingsbridge, which in 1874 was annexed to the city of New York, and in 1898 became a part of the borough of the Bronx, New York City.

FORDUN, JOHN OF (d. c. 1384), Scottish chronicler. The statement generally made that the chronicler was born at Fordoun (Kincardineshire) has not been supported by any direct evidence. It is certain that he was a secular priest, and that he composed his history in the latter part of the 14th century; and it is probable that he was a chaplain in the cathedral of Aberdeen. The work of Fordun is the earliest attempt to write a continuous history of Scotland. We are informed that Fordun's patriotic zeal was roused by the removal or destruction of many national records by Edward III, and that he travelled in England and Ireland, collecting material for his history. This work is divided into five books. The first three are almost entirely fabulous, and form the groundwork on which Boece and Buchan afterwards based their historical fictions, which were exposed by Thomas Innes in his Critical Essay (i. pp. 291-214). The 4th and 5th books, though still mixed with fable, contain much valuable information, and become more authentic the more nearly they approach the author's own time. The 5th book concludes with the death of King David I. in 1153. Besides these five books, Fordun wrote part of another book, and collected materials for bringing down the history to a later period. These materials were used by a continuator who wrote in the middle of the 15th century, and who is identified with Walter Bower (q.v.), abbot of the monastery of Inchcolm. The additions of Bower form eleven books, and bring down the narrative to the death of King James I. in 1437.
to the custom of the time, the continuator did not hesitate to interpolate Fordun's portion of the work with additions of his own, and the whole history thus compiled is known as the Scotichronicon.

The first printed edition of Fordun's work was that of Thomas Gale in his Scriptores quindecim (vol. iii.), which was published in 1601. This was followed by Thomas Hearne's (5 vols.) edition in 1722. The whole work, including Bower's continuation, was published by Walter Goodall at Edinburgh in 1759. In 1871 and 1872 Fordun's work, the original Latin text, was edited by William F. Skene in The Historians of Scotland. The preface to this edition collects all the biographical details and gives full bibliographical references to MSS. and editions.

**FORECLOSURE**, in the law of mortgage, the extinguishment by order of the court of a mortgagee's equity of redemption. In the law of equity the object of every mortgage transaction is eventually the repayment of a debt, the mortgaged property being incidental by way of security. Therefore, although the day named for repayment of the loan has passed and the mortgagor's estate is consequently forfeited, equity steps in to maintain the harmony of the common law, and will decree a reconveyance of the mortgaged property on payment of the principal, interest and costs. This right of the mortgagor to relief is termed his "equity of redemption." But the right must be exercised within a reasonable time, otherwise he will be foreclosed his equity of redemption and the mortgagee's possession converted into an absolute ownership. Such foreclosure is enforced by equity by a foreclosure action. An action is brought by the mortgagee against the mortgagor in the chancery division of the High Court in England, claiming that an account may be taken of the principal and interest due to the mortgagee, and that the mortgagor may be directed to pay the same, with costs, by a day to be appointed by the court and that in default thereof he may be foreclosed his equity of redemption. English county courts have jurisdiction in foreclosure actions where the mortgage or charge does not exceed £500, or where the mortgage is for more than £500, but less than that sum has been actually advanced. In a Welsh mortgage there is no right to foreclosure. (See also MORTGAGE.)

**FOREIGN OFFICE**, that department of the executive of the United Kingdom which is concerned with foreign affairs. The head of the Foreign Office is termed principal secretary of state for foreign affairs and his office dates from 1782. Between that date and the Revolution there had been only two secretaries of state, whose duties were divided by a geographical division of the globe into northern and southern departments. The duties of the secretary of the northern department of Europe comprised dealings with the northern powers of Europe, while the secretary of the southern department dealt with territories occupied with France, Spain, Portugal, Switzerland, Italy, Turkey, and also looked after Irish and colonial business, and carried out the work of the Home Office. In 1782 the duties of these two secretaries were revised, the northern department becoming the Foreign Office. The secretary for foreign affairs is the official agent of the crown in all communications between Great Britain and foreign powers; his intercourse is carried on either through the representatives of foreign states in Great Britain or through representatives that British diplomats may meet abroad. He negotiates all treaties or alliances with foreign states, projects British subjects residing abroad, and demands satisfaction for any injuries they may sustain at the hands of foreigners. He is assisted by two under-secretaries of state (one of them a politician, the other a permanent civil servant), three assistant under-secretaries (civil servants), a librarian, a head of the treaty department and a staff of clerks. The departments of the Foreign Office are the African, American, commercial and sanitary, consular, eastern (Europe), far eastern, western (Europe), parliamentary, financial, philosophical, and a register of the papers, treaties and registry. In the case of important despatches and correspondence, these, with the drafts of answers, are sent first to the permanent under-secretary, then to the prime minister, then to the sovereign and, lastly, are circulated among the members of the cabinet. The salary of the secretary for foreign affairs is £5,000 per annum, that of the permanent under-secretary £2,000, the parliamentary under-secretary and the first assistant under-secretary, £1,500, and the other assistant under-secretaries £1,200.

See Anson, Law and Custom of the Constitution, part ii.

**FORELAND, NORTH and SOUTH**, two chalk headlands on the Kent coast of England, overlooking the Strait of Dover, the North Foreland forming the eastern projection of the Isle of Thanet, and the South standing 3 m. N.E. of Dover. Both present bold cliffs to the sea, and command beautiful views over the strait. On the North Foreland (51° 22' N., 1° 27' E.) there is a lighthouse, and on the South Foreland (51° 83' N., 1° 25' E.) there are two. There is also a Foreland on the north coast of Devonshire, 23 m. N.E. of Lynmouth, a fine projection of the highlands of Exmoor Forest, overlooking the Bristol Channel, and forming the most northerly point of the county.

**FORESHORE**, that part of the seashore which lies between high and low-water mark at ordinary tides. In the United Kingdom it is ordinarily and prima facie vested in the crown, except where it may be vested in a subject by ancient grant or charter from the crown, or by prescription. Although numerous decisions, dating from 1795, have confirmed the prima facie title of the crown, S. A. Moore in his History of the Foreshore contends that the presumption is in favour of the subject rather than the crown. But a subject can establish a title by proving an express grant from the crown or giving evidence of a user from which a grant may be presumed. The chief acts showing title to foreshore are, taking wreck or royal fish, right of fishing, mining, digging and taking sand, seaweed, &c., embanking and enclosing. There is a public right of user in that part of the foreshore which belongs to the crown, for the purpose of navigation or fishery, but there is no right of passage over lands adjacent to the shore, except by a particular custom. So that, in order to make the right available, there must be a highway or other public land giving access to the foreshore. Thus it has been held that the public have no legal right to pass over land above high-water mark for the purpose of bathing in the sea, though if they can get to it they may bathe there (Blundell v. Catteral, 1821, 5 B. & Ad. 268). There is no right in the public to take sand, shells or seaweed from the shore, nor, except in certain places by local custom, have fishermen the right to use the foreshore or the soil above it for drawing up their boats, or for drying their nets or similar purposes.

See S. A. Moore, History of the Foreshore and the Law relating thereto (1888); Coulson and Forbes, Law of Waters (1905).

**FORESTALLING**, in English criminal law, the offence of buying merchandise, victual, &c., with a view to market, or making any bargain for buying the same, before they shall be in the market ready to be sold, or making any motion for enhancing the price, or dissuading any person from coming to market or forbearing to bring any of the things to market, &c. See ENGROSSING.

**FOREST LAWS**, the general term for the old English restriction laws, dealing with forests. One of the most cherished prerogatives of the king of England, at the time when his power was at the highest, was that of converting any portion of the country into a forest in which he might enjoy the proceeds of the chase. The management of forests was placed in the hands of the king and the people testify to the extent to which this prerogative became a public grievance, and the charter by which its exercise was bounded (Carta de Foresta) was in substance part of the greatest constitutional code imposed by his barons upon King John. At common law it appears to have been the right of the king to make a forest where he pleased, provided that certain legal formalities were observed. The king having a continual care for the preservation of the realm, and for the peace and quiet of his subjects, he had therefore amongst many privileges this prerogative, viz., to have his parks of recreation wherever he would appoint. 1 Land once afforested became subject to a peculiar system of laws, which, as well as the formalities required to constitute a valid afforestation, have been carefully ascertained by the Anglo-Norman lawyers. "A forest," 1 Coke, 4 Inst., 300.
says Manwood, "is a certain territory of woody grounds and fruitful pastures, privileged for wild beasts and fowls of forest, chase, and warren to rest, and abide there in the safe protection of the king, for his delight and pleasure; which territory of ground so privileged is mered and bounded with unremovable marks, meres and boundaries, either known by matter of record or by prescription; and also replenished with wild beasts of venery or chase, and with great covertis of vert, for the succour of the said beasts there to abide: for the preservation and continuance of which said place, together with the vert and venery there are particular offenses of law, and privileges belonging to the same, requisite for that purpose, and proper only to a forest and to no other place." And the same author distinguishes a forest, as "the highest franchise of princely pleasure," from the inferior franchises of chase, park and warren—named in the order of their importance. The forest embraces all these, and it is distinguished by having laws and courts of its own, according to which offenders are justiciable. An offender in a chase is to be punished by the common law; an offender in a forest by the forest law. A chase is much the same as a park, only the latter is enclosed, and all of them made under augmentation according to the class of wild beasts to which the privilege extended. Thus beasts of forest (the "five wild beasts of venery") were the hart, the hind, the hare, the boar and the wolf. The beasts of chase were also five, viz., the buck, the doe, the fox, the marten and the roe. The beasts and fowls of warren were the hare, the coney, the pheasant and the partridge.

The courts of the forest were three in number, viz. the court of attachments, swainmote and justice-seat. The court of attachments (called also the wood-mote) is held every forty days for the foresters to bring in their attachments concerning any hurt done to vert or venison (in viridi et venatione) in the forest, and for the verderers to receive and mark the same, but no conviction takes place. The swainmote, held three times in the year, is the court to which all the freeholders within the forest owe suit and service, and of which the verderers are the judges. In this court all offences against the forest laws may be tried, but no judgment or punishment follows. This is reserved for the justice-seat, held every third year, to which the rolls of offences presented at the court of attachment, and tried at the swainmote, are presented by verderers. The justice-seat is the court of the chief justiceman, who, says Coke, "is commonly a man of greater dignity than knowledge of the laws of the forests; and therefore where justice-seats are to be held some other persons whom the king shall appoint are associated with him, who together are to determine omnia placita forestae." There were two chief justices for the forests intra and ultra Trentum respectively. The necessary officers of a forest are a steward, verderers, foresters, regiders, agisters and woodwards. The verderer was a judicial officer chosen in full county by the freeholders in the same manner as the coroner. His office was to view and receive the attachments of the foresters, and to mark them on his rolls. A forester was "an officer sworn to preserve the vert and venison in the forest, and to attend upon the wild beasts within his bailiwick." The regiders were of the nature of visitors: their duty was to make a record (visitationes) every third year, to inquire of all offenses, and of the concealment of such offenses by any officer of the forest. The business of the agister was to look after the pasturage of the forest, and to receive the payments for the same by persons entitled to pasture their cattle in the forests. Both the pasturage and the payment were called "agistment." The woodward was the officer who had the care of the woods and vert and presented offenses at the court of attachment.

The legal conception of a forest was thus that of a definite territory within which the code of the forest law prevailed to the exclusion of the common law. The ownership of the soil might be in any one, but the rights of the proprietor were limited by the laws made for the protection of the king's wild beasts. These laws, enforced by fines often arbitrary and excessive, were a great grievance to the unfortunate owners of land within or in the neighbourhood of the forest. The offence of "purpresture" may be cited as an example. This was an encroachment on the forest rights, by building a house within the forest, and it made no difference whether the land belonged to the builder or not. In either case it was an offence punishable by fines at discretion. And if a man converted woodlands within the forest into arable land, he was guilty of the offence known as "assarting," whether the covert belonged to himself or not.

The hardships of the forest laws under the Norman kings, and their extension to private estates by the process of aforestation, were among the principal causes which induced the people against the king in the reign of John. The Great Charter of King John contains clauses relating to the forest laws, but no separate charter of the forest. The first charter of the forest is that of Henry III., issued in 1217. "As an important piece of legislation," said Stubbs, it must be compared with the forest assize of 1184, and with 44th, 47th and 48th clauses of the charter of John. It is observable that most of the abuses which are remedied by it are regarded as having sprung up since the accession of Henry II.; but the most offensive aforestations were those under Richard and John. These latter are of once disafforested; but those of Henry II. only so far as they had been carried out to the injury of the landowners and outside of the royal demesne." Land which had thus been once forest land and was afterwards disafforested was known as purliew—derived by Manwood from the French pur and lieu, i.e. "a place exempt from the forest." The forest laws still applied in a modified manner to the purliew. The benefit of the disafforestation existed only for the owner of the lands; as to all other persons the land was forest still, and the king's wild beasts were "have free recourse therein and safe return to the forest, without any hurt or destruction other than by the owners of the lands in the purliew where they shall be found, and that only to hunt and chase them back again towards the forest without any forestalling." (Manwood, On the Forest Laws—article "Purlieu").

The revival of the forest laws was one of the means resorted to by Charles I. for raising a revenue independently of parliament, and the royal forests in Essex were so enlarged that they were hyperbolically said to include the whole county. The 4th earl of Southampton was nearly ruined by a decision that stripped him of his right in Rockingham Forest. The boundaries of the royal forests were increased from 6 m. to 60, and enormous fines imposed on the trespassers.—Lord Salisbury being assessed in £20,000, Lord Westmoreland in £19,000, Sir Christopher Hatton in £12,000 (Hallam's Constitutional History of England, c. viii.). By the statute 16 Charles I. c. 16 (1640) the royal forests were determined for ever according to their boundaries in the twentieth year of James, all subsequent enlargements being annulled.

The forest laws, since the Revolution, have fallen into complete disuse.

**FORESTS AND FORESTRY.** Although most people know what a forest (Lat. foris, "out of doors") is, a definition of it which suits all cases is by no means easy to give. Manwood, in his treatise of the Laws of the Forest (1598), defines a forest as "a certain territory of woody grounds, fruitful pastures, privileged for wild beasts and fowls of forest, chase and warren, to rest and abide in, in the safe protection of the king, for his princely delight and pleasure." This primitive definition has, in modern times, when the economic aspects of forests came more into the foreground, given place to others, so that forest may, in a general way, now be described as "an area which is for the most part set aside for the production of timber and other forest produce, or which is expected to exercise certain climatic effects, or to protect the locality against injurious influences."

As far as conclusions can now be drawn, it is probable that the greater part of the dry land of the earth was, at some time, covered with forest, which consisted of a variety of trees and shrubs grouped according to climate, soil and configuration of the several localities. When the old trees reached their limit

of life, they disappeared, and younger trees took their place. The conditions for an uninterrupted regeneration of the forest were favourable, and the result was vigorous production by the creative powers of soil and climate. Then came man, and by degrees interfered, until in most countries of the earth the area under forest has been considerably reduced. The first decided interference was probably due to the establishment of domestic animals; even burnt the forest to obtain pasture for their flocks. Subsequently similar measures on an ever-increasing scale were employed to prepare the land for agricultural purposes. More recently enormous areas of forests were destroyed by reckless cutting and subsequent firing in the extraction of timber for economic purposes.

It will readily be understood that the distribution and character of the new remaining forests must differ enormously (see PLANTS: Distribution). Large portions of the earth are still covered with dense masses of tall trees, while others contain low scrub or grass land, or are desert. As a general rule, natural forests consist of a number of different species intermixed; but in some cases certain species, called gregarious, have succeeded in obtaining the upper hand, thus forming more or less pure forests of one species only. The number of species differs very much. In many tropical forests hundreds of species may be found on a comparatively small area, in other cases the number is limited. Burma has several thousand species of trees and shrubs, Sind has only ten species of trees. Central Europe has about forty species, and the greater part of northern Russia, Sweden and Norway consists of about half a dozen species. There are also cases of the Mediterranean with forests of cork oak; then Italy with oak, olive, chestnut, gradually giving place to ash, sycamore, beech, birch and certain species of pine; in Switzerland and Germany silver fir and spruce gain produced. Silver fir disappears in central Germany, and the countries around the Baltic contain forests consisting chiefly of Scotch pine, spruce and birch, to which, in Siberia, larch must be added, while the lower parts of the ground are stocked with hornbeam, willow, alder and poplar. In North America the distribution is as follows: Tropical vegetation is found consisting, according to latitude and elevation, above the sea, of pines, larches, fir, Thuja and Tsuga. In Japan a tropical vegetation is found in the south, comprising palms, firs, eony, mangrove and others. This is followed on proceeding north by subtropical forests consisting of evergreen oaks, Podocarpus, tree-ferns, and, at higher elevations, Cryptomeria and Chamaecyparis. They then follow deciduous broad-leaved forests, and finally firs, spruces and larches. In India the character of the forests is governed chiefly by rainfall and elevation. Where the former is heavy evergreen forests of Guttiferae, Dipterocarpaceae, Leguminosae, Euphorbias, firs, palms, ferns, bamboos and India-rubber trees are found. Under a less continuous rainfall deciduous forests appear, containing teak and sal (Shorea robusta) and a great variety of other valuable trees. Under a still smaller rainfall the vegetation becomes sparse, containing acacias, Dalbergia sissoo and Tamarix. Where the rainfall is very light or nil, desert appears. In the Himalayas, subtropical to arctic conditions are found, the forests containing, according to elevation, pines, firs, deodars, oaks, chestnuts, magnolias, laurels, rhododendrons and bamboos. Australia, again, has its own particular flora of eucalypts, of which some two hundred species have been distinguished, as well as wattles. Some of the eucalypts attain an enormous height.

Utility of Forests.—In the economy of man and of nature forests are of direct and indirect value, the former chiefly through the produce which they yield, and the latter through the influence which they exercise upon climate, the regulation of moisture, the stability of the soil, the healthiness and beauty of a country and allied subjects. The indirect utility will be dealt with first. A piece of land bare of vegetation is, throughout the year, exposed to the full effect of sun and air currents, and the climatic conditions which are produced by these agencies. If, on the other hand, a piece of land is covered with a growth of plants, and especially with a dense crop of forest vegetation, it enjoys the benefit of certain agencies which modify the effect of sun and wind on the soil and the adjoining layers of air. These modifying agencies are as follows: (1) The crowns of the trees intercept the rays of the sun and the falling rain; they obstruct the movement of air currents, and reduce radiation at night. (2) The leaves, flowers and fruits, augmented by certain plants which grow in the shade of the trees, form a layer of mould, or humus, which helps to fix nitrogen gas against rapid changes of temperature, and greatly influences the development of water in it. (3) The roots of the trees penetrate into the soil in all directions, and bind it together. The effects of these agencies have been observed from ancient times, and widely differing views have been taken of them. Of late years, however, more careful observations have been made at so-called parallel stations, that is to say, one station in the middle of a forest, and another outside at some distance from its edge, but otherwise exposed to the same general conditions. In this way, the following results have been obtained: (1) Forests reduce the temperature of the air and soil to a moderate extent, and render the climate more equable. (2) They increase the relative humidity of the air, and reduce evaporation. (3) They tend to increase the precipitation of moisture. As regards the actual rainfall, their effect in low lands is nil or very small; in hilly countries it is probably greater, but definite results have not yet been obtained owing to the difficulty of separating the effect of forests from that of other factors. (4) They help to regulate the water supply, produce a more sustained feeding of springs, tend to reduce violent floods, and render the flow of water in rivers more regular. (5) The soils of forests are usually richer in humus and ash, and their cultivation is more profitable. (6) They give shelter to cattle, game and useful birds. They may, under certain conditions, improve the healthiness of a country, and help in its defence. They increase the beauty of a country, and produce a healthy aesthetic influence upon the people.

The direct utility of forests is chiefly due to their produce, the chief of which they represent, and the work which they provide. The principal produce of forests consists of timber and firewood. Both are necessary for the daily life of the people. Apart from a limited number of broad-leaved species, the conifers have become the most important timber trees in the economy of man. They are found in greatest quantities in the countries around the Baltic and in North America. In modern times iron and other materials have, to a considerable extent, replaced timber, while coal, lignite, and peat compete with firewood; nevertheless wood is still indispensable, and likely to remain so. This is borne out by the statistics of the most civilized lands. Wherever the population of Great Britain and Ireland, during the period 1886-1906, increased by about 20%, the imports of timber, during the same period, increased by 45%; in other words, every head of population in 1900 used more timber than
twenty years earlier. Germany produced in 1889 about as much timber as she required; in 1899 she imported 4,000,000 tons, valued at £14,000,000, and her imports are rapidly increasing, although the yield capacity of her own forests is much higher now than it was formerly. Wood is now used for many purposes which formerly were not thought of. The manufacture of the wood pulp annually imported into Britain consumes at least 2,000,000 tons of timber. A fabric closely resembling silk is now made of spruce wood. The variety of other, or minor, produce yielded by forests is very great, and much of it is essential for the well-being of the people for various purposes. The yield of fodder is of the utmost importance in countries subject to periodic droughts; in many places field crops could not be grown successfully without the leaf-mould and brushwood taken from the forests. As regards industries, attention need only be drawn to such articles as commercial fibre, tanning materials, dye-stuffs, lac, turpentine, resin, rubber, gutta-percha, &c. Great Britain and Ireland alone import every year such materials to the value of £12,000,000, half of this being represented by timber.

The capital employed in forests consists chiefly of the value of the soil and growing stock of timber. The latter is, ordinarily, of much greater value than the former wherefor a sustained annual yield of timber is expected from a forest. In the case of a Scotch pine forest, for instance, the value of the growing stock is, under the above-mentioned condition, from three to five times that of the soil. The rate of interest yielded by capital invested in forests differs, of course, considerably according to circumstances, but on the whole it may, under proper management, be placed equal to that yielded by agricultural land; it is lower than the agricultural rate on the better classes of land, but higher on the inferior classes. Hence the latter are specially indicated for the forest industry, and the former for the production of agricultural crops. Forests require labour in a great variety of ways, such as (1) general administration, formation, tending and harvesting; (2) transport of produce; and (3) industries which depend on forests for their prime material. The labour indicated under the first head differs considerably according to circumstances, but its amount is smaller than that required if the land is used for agriculture. Hence forests provide additional labour only if they are established on surplus lands. Owing to the bulky nature of forest produce its transport forms a business of considerable magnitude, the amount of labour being perhaps equal to half that employed under the first head. The greatest amount of labour is, however, required in the working up of the raw material yielded by forests. In this respect attention may be drawn to the chair industry in and around High Wycombe in Buckinghamshire, where more than 20,000 workmen are employed in converting the beech, grown on the adjoining chalk hills, into chairs and tools of many patterns. Complete statistics for Great Britain are not available under this head, but it may be mentioned that in Germany the people employed in the forests amount to 2·3 % of the total population; those employed on transport of forest produce 1·1 %; labourers employed on the various wood industries, 8·6 %; or a total of 12 %. An important feature of the work connected with forests and their produce is that a great part of it can be made to fit in with the requirements of agriculture; that is to say, it can be done at seasons when field crops do not require attention. Thus the rural labourers or small farmers can earn some money at times when they have nothing else to do, and when they would probably sit idle if no forest work were obtainable.

Whether, or how far, the utility of forests is brought out in a particular country depends on its special conditions, such as (1) the position of a country, its communications, and the control which it exercises over other countries, such as colonies; (2) the quantity and quality of substitutes for forest produce available in the country; (3) the value of land and labour, and the agricultural possibilities used for other purposes; (4) the density of population; (5) the amount of capital available for investment; (6) the climate and configuration, especially the geographical position, whether inland or on the border of the sea, &c. No general rule can be laid down, showing whether forests are required in a country, or, if so, to what extent; that question must be answered according to the special circumstances of each case.

</table>

These data exhibit considerable differences, since the percentage of the forest area varies from 3·5 to 50, and the area per head of population from 0·7 to 9·3 acres. Russia, Sweden, and Norway may as yet have more forest than they require for their own population. On the other hand, Great Britain and Ireland, Germany, Denmark, Portugal, Holland, and even Belgium, France and Italy have not a sufficient forest area to meet their own requirements; at the same time, they are all sea-bound countries, and importation is easy, while most of them are under the influence of moist sea winds, which reduces to a subordinate position the importance of forests for climatic reasons.

Intimately connected with the area of forests in a country is the state of ownership—whether they belong to the state, corporations or to private persons. Where, apart from the financial aspect and the supply of work, forests are not required for the sake of their indirect effects, and where importation from other countries is easy and assured, the government of the country need not, as a rule, trouble itself to maintain or acquire forests. Where the reverse conditions exist, and especially where the cost of transport over long distances becomes prohibitive, a wise administration will take measures to assure the maintenance of a suitable proportion of the country under forest. This can be done either by maintaining or constituting a suitable area of state forests, or by exercising a certain amount of control over corporation and even private forests. Such measures are more called for in continental countries than in those which are sea-bound, as is proved by the above statistics.

Supply of Timber — Imports and Exports.—The following table shows the net imports and exports of European countries (average data, calculated from the returns of recent years).

The only timber-exporting countries of Europe are Russia, Sweden, Norway, Austria-Hungary and Rumania; all the others have only enough for their own consumption, or import timber. Great Britain and Ireland import now upwards of 10,000,000 tons a year, Germany about 4,600,000 tons, and
Belgium about 1,300,000 tons. Holland, France, Portugal, Spain and Italy are all importing countries, as also are Asia Minor, Egypt and Algeria. The west coast of Africa exports hardwoods, and imports coniferous timber. The Cape and Natal import considerable quantities of pine and fir wood. Australasia exports hardwoods and some Kauri pine from New Zealand, but imports larger quantities of light pine and fir timber. British India and Siam export teak and small quantities of fancy woods. The West Indies and South America export hardwoods, and import pine and fir wood. The United States of America will not much longer be a genuine exporting country, since they import already almost as much timber from Canada as they export. Canada exports considerable quantities of timber. The Dominion has still a forest area of 1,250,000 sq. m., equal to 16% of the total area, and giving 165 acres of forest for every inhabitant. Although only about one-third of the forest area can be called regular timber land, Canada possesses an enormous forest wealth, with which she might supply permanently nearly all other countries deficient in material, if the governing bodies in the several provinces would only determine to stop the present fearful waste caused by axe and fire, and to introduce a regular system of management. As matters stand, the supplies of the most valuable timber of Canada, the white or Weymouth pine (Pinus strobus), are nearly exhausted, the great stores of spruce in the eastern provinces are being rapidly destroyed, and the forests of Douglas fir in the western provinces have been attacked for export to the United States and to other countries.

Taking the remaining stocks of the whole earth together, it may be said that a sufficient quantity of hardwoods is available, but the only countries which are able to supply coniferous timber for export on a considerable scale are Russia, Sweden, Norway, Austria and Canada. As these countries have practically to supply the rest of the world, and as the management of their forests is far from satisfactory, the question of supplying light pine and fir timber, which forms the very staff of life of the wood industries, must become a very serious matter before many years have passed. Unmistakeable signs of the coming crisis are everywhere visible to all who wish to see, and it is difficult to over-estimate the gravity of the problem, when it is remembered, for instance, that 87% of all the timber imported into Great Britain consists of light pine and fir, and that most of the other importing countries are similarly situated. In some of these countries little or no room exists for the extension of woodland, but this statement does not apply to Great Britain and Ireland, which contain upwards of 12,000,000 acres of waste land, and 12,500,000 acres of mountain and heath land used for light grazing. One-fourth of that area, if put under forest, would produce all the timber now imported which can be grown in Britain, that is to say, about 95% of the total.

The subjoined table shows the movements of timber within the greater part of the British empire:

Forest Management.—In early times there was practically no forest management. As long as the forests occupied considerable areas, their produce was looked upon as the free gift of nature, like air and water; men took it, used it, and even destroyed it without let or hindrance. With the gradual increase of population and the consequent reduction of the forest area, proprietary ideas developed; people claimed the ownership of certain forests, and proceeded to protect them against outsiders. Subsequently the law of the country was called in to help in protection, leading to the promulgation of special forest laws. By degrees it was found that mere protection was not sufficient, and that steps must be taken to enforce a more judicious treatment, as well as to limit the removal of timber to what the forests were capable of producing permanently. The teaching of natural science and of political economy was brought to bear upon the subject, so that now forestry has become a special science. This is recognized in many countries, amongst which Germany stands first, closely followed by France, Austria, Denmark and Belgium. Of non-European countries the palm belongs to British India, and then follow Ceylon, the Malay States, the Cape of Good Hope and Japan. The United States of America have also turned their attention to the subject. Most of the British colonies are, in this respect, as yet in a backward state, and the matter has still to be fought out in Great Britain and Ireland, though many writers have urged the importance of the question upon the public and the government. There can be no doubt that all civilized countries must, sooner or later, adopt a rational and systematic treatment of their forests.

For details as to the separate countries, see the articles under the country headings; in this article only some of the more important countries are dealt with, in so far as the history of their forestry is important. A few notes on Germany and France will be given, because in these countries forest management has been brought to highest perfection; Italy is mentioned, because she has allowed her forests to be destroyed; and a short description of forestry in the United Kingdom and in India follows. A separate section is devoted to the United States.

Germany is in general well-wooded. The winters being long and severe, an abundant supply of fuel is almost as essential as a sufficient supply of food. This necessity has led, along
with a passion for the chase, to the preservation of forests, and
to the establishment of an admirable system of forest cultivation,
almost as carefully conducted as field vallage. The Black Forest
stretches the whole length of the grand-duchy of Baden and part of
the kingdom of Wurtemberg, from the Neckar to Basel and the
Lake of Constance. The vegetation resembles that of the
Vosges; forests of spruce, silver fir, Scotch pine, and, mingled
with birches, beech and oak, are the chief woods met with.
Until comparatively recent times large quantities of timber
derived from these forests were floated down the Rhine to Holland
and the English Channel. Now, however, the chief woods
of this region are employed locally for construction, or it is converted into paper pulp. In
the grand-duchy of Hesse the Odenwald range of mountains,
stretching between the Main and the Neckar, contains the chief
supply of timber. In the province of Nassau there are the large
wooded tracts of the Taunus mountain range and the Westerwald.

In Rhenish Prussia valuable forests lie partly in the Eifel,
on the borders of Belgium, and on the mountains overhanging the
Upper Moselle, but they do not furnish such stately trees as the Black Forest and the Odenwald. The Spessart, near Aschaffenburg in Bavaria, is one of the most extensive forests of middle Germany, containing large masses of fine oak and beech,
with plantations of coniferous trees, such as spruce, Scotch pine and
driver fir. Bavaria possesses other fine forest tracts, such as the Baierschewald on the Bohemian frontier, the Kranzberg
north of Mainz, and the Frankenwald in the north of the kingdom.

North Germany has extensive forests on the Harz and Thuringian
Mountains, while in East Prussia large tracts of flat ground are
covered with Scotch pine, spruce, oak and beech.

Every German state has its forest organization. In Prussia the
department is presided over by the Oberland Forstmeister
at Berlin, while each province, or part of a province, has an
Oberforstmeister, under whom a number of Oberforstmeister admini-
strate the state and communal forests. These, again, are assisted
by a lower class of officials called Försters. The Oberforstmeister
throughout Germany are educated at special schools of forestry,
of which in 1900 the following nine existed:

In Prussia: at Eberswalde and Müden.
In Bavaria: at Munich and Aschaffenburg.
In Saxony: at Tharand.
In Württemberg: at Tübingen.
In Baden: at Karlsruhe.
In Hesse: at Giessen.
In the grand-duchy of Saxony: at Eisenach.

The schools at Munich, Tübingen and Giessen form part of the
universities at these places; that at Karlsruhe is attached to the
technical high school; the others are academies for the study of
deforestation only, but there is a tendency to transfer them all
to the universities. The subordinate staff are trained for their
work in so-called silvicultural schools, of which a large
number exist. In this way the German forests have been brought
to a high degree of productiveness, but the material derived from
them falls far short of the requirements of the population, although
they occupy 26% of the total area of the country; hence the net
imports of timber amount already to 4,600,000 tons a year, and
they are steadily rising.

France.—The principal timber tree of France is the oak. The
cork oak is grown extensively in the south and in Corsica. The
beech, ash, elm, maple, birch, walnut, chestnut and poplar are all
important trees, while the silver fir and spruce form magnificent
forests in the Vosges and Jura Mountains, and the Apennine and
maritime pines. Coniferous forests are cultivated in the south and south-west. About
one-seventh of the entire territory is still covered with wood.

Forest legislation took its rise in France about the middle of
the 16th century, and the great minister Sully urged the enforce-
ment of restrictive forest laws. In 1669 a fixed treatment of
state forests was enacted. Duhamel in 1755 published his famous
work on forest trees. Reckless destruction of the forests, however,
was in progress, and the Revolution of 1789 gave a fresh stimulus
to the work of devastation. The usual results have followed in the
frequency and destructiveness of floods, which have washed away the soil from the hillsides and valleys of many districts,
especially in the south, and the frequent inundations of the last
fifty years are no doubt caused by the deforesting of the sources of
the Rhone and Saône. Laws were passed in 1866 and 1864, providing for the reforesta-
tion, "reboisement," of the slopes of mountains, and these laws take effect on private as well as
state property. Thousands of acres are annually planted in the
departments of Hautes and Basses Alpes; and during the summer of
1875, when much injury was done by floods in the south of
France, the Durance, formerly the most dangerous in this respect
of French rivers, gave little cause for anxiety, as it is round the
lower course in the Provence district. New woods have been
formed. While tracts formerly covered with wood have been replanted, plantations have been formed on the shifting sands or
dunes along the coast of Gascogne. A forest of Pinus pinaster,
150 m. in length, now stretches from Bayonne to the mouth of
the Gironde, raised by means of sowing steadily continued since
1789; the cultivation of the pine, along with draining, has
transformed low marshy grounds into productive soil extending
over an area of about two million acres. The forests thus created provide annually some 600,000 tons of pit timber for the
Welsh coch.

The state forest department is administered by the director-
general, who has his headquarters at Paris, assisted by a board
of administration, charged with the working of the forests, questions of rights and law, finance and plantation works.

The department is supplied with officers from the forest
school at Nancy. This institution was founded in 1824, when
M. Lorentz, who had studied forestry in Germany, was appointed
its first director.

Italy.—The kingdom of Italy comprises such different climates
that within its limits we find the birch and pines of northern
Europe, the olive, fig, almond, chestnut, and palm of more southern
latitudes. By the republic of Venice and the duchy of Genoa
forestal legislation was attempted at various periods from the
15th century downwards. These efforts were not successful, as the governments were lax in enforcing the laws. In
1789, Pius VI. issued regulations prohibiting felling without licence,
and later orders were published by his successors in the pontifical
states. In Lombardy the woods, which in 1830 reached nearly
down to Milan, have almost disappeared. The province of Como
contains only a remnant of the primitive forests, and the same
may be said of the southern slopes of Tirof. At Ravenna there is still a large forest of stone pine, Pinus pinea, though it
has been much reduced. The plains of Tuscany are adorned
with planted trees, the olive, mulberry, fig and almond. Sardinia
is rich in woods, which cover one-fifth of the area, and contain
a large amount of oak, Quercus suber, robur and cersis. In Sicily
the forests have long been felled, save the zone at the base of
Mount Etna.

The destruction of woods has been gradual but persistent;
at the end of the 17th century the effects of denudation were
first felt in the destructive force given to mountain torrents
by the deforestation of the Apennines. The work of devastation continued until a comparatively recent time.

In 1867 the monastic property of Vallombrosa, Tuscany,
30 m. from Florence, was purchased by government for the
purposes of a forest academy, which was opened in 1869. As
only 4% of the total forest area belongs to the state, it is doubtful
whether much good can now be done.

Great Britain and Ireland.—The British Isles were formerly
much more extensively wooded than at present. The rapid
increase of population led to the deforestation of woodland; the
climatic changes required the maintenance of household fires during a
great part of the year, and the increasing demand for arable
land and the extension of manufacturing industries combined
to cause the diminution of woodland. The proportion of forest
is now very small, and yields but a fraction of the required annual
supply of timber which is imported with facility from America,
northern Europe and the numerous British colonies.

Owing to the nature of the climate of the British Islands,
with its abundance of atmospheric moisture and freedom from
such extremes of heat and cold as are prevalent in continental
Europe, a great variety of trees are successfully cultivated. In England and Ireland oak and beech are on the whole the most plentiful trees in the low and fertile parts; in the south of Scotland the beech and ash are perhaps most common, while the Scotch fir and birch are characteristic of the highlands. In the Highlands of Scotland, as well as in the Highlands of Ireland, there are extensive forests now exist, woods of small area, belts of planting, clumps of trees, coppice and hedgerows, are generally distributed over the country, constituting a mass of wood of considerable importance, giving a clothed appearance in many parts, and affording illustrations of skilful arboriculture not to be found in any other country.

The principal state forests in England are Windsor Park, 14,000 acres; the New Forest, &c., in Hampshire, 76,000 acres; and the Dean Forest in Gloucestershire, 22,900 acres. The total extent of crown forests is about 135,000 acres. A large proportion of the crown forests, having been formed with the object of supplying timber for the navy, consists of oak. The largest forests in Scotland are in Perthshire, Inverness-shire and Aberdeenshire. Of these the most notable are the earl of Mansfield's near Scone (8000 acres), the duke of Atholl's larch plantations near Dunkeld (10,000 acres), and in Stratheg a large extent of Scotch pine, partly native, partly planted, belonging to the earl of Seafield. In the forests of Mar and Invercauld, the native pine attains a great size, and there are also large tracts of indigenous birch in various districts. Ireland was at one time richly clothed with wood; this is proved by the abundant remains of fallen trees in the bogs which occupy a large surface of the island. In addition to the causes above alluded to as tending to disforest England, the long unsettled state of the country also conducted to the diminishing of the woodlands.

The forests of Great Britain and Ireland, in spite of the large imports of timber, have not been appreciably extended up to the present time because (1) the rate at which foreign timber has been laid down in Britain is very low, thus keeping down the price of home-grown timber; (2) preference is given to home-grown material, because it is in many cases of superior quality, while the latter comes into the market in an irregular and intermittent manner; (3) nearly the whole of the waste lands is private property. As regards prices, it can be shown that the lowest point was reached about the year 1888, in consequence of the remarkable development of means of communication, that prices then remained fairly stationary for some years, and that about 1894 a slow but steady rise set in, showing during the years 1894-1904 an increase of about 20 % all round. This was due to the gradual approach of the coming crisis in the supply of coniferous timber to the world. It can be shown that even with present prices the growing of timber can be made to pay, provided it is carried on in a rational and economic manner. Improved silvicultural methods must be applied, so as to produce a better class of timber, and the forests must be managed according to well-arranged working plans, which provide for a regular and sustained out-turn of timber by year, so as to develop a healthy and steady market for locally-grown material. Unfortunately the private proprietors of the waste lands are in many cases not in a financial position to plant. Starting forests demands a certain outlay in cash, and the proprietor must forgo the income, however small, hitherto derived from the land until the plantations begin to yield a return. In these circumstances the state may well be expected to help in one or all of the following ways: (1) The equipment of forest schools, where economic forestry, as elaborated by research, is taught; (2) the management of the crown forests on economic principles, so as to serve as patterns to private proprietors; (3) advances should be made to the landowners who desire to plant land, but are short of funds, just as is done in the case of improvements of agricultural holdings; and (4) the state might acquire surplus lands in certain parts of the country, such as congested districts, and convert them into forests. Action in these directions would soon lead to substantial benefits. The income of landed proprietors would rise, a considerable sum of money now sent abroad would remain in the country, and forest industries would spring up, thus helping to counteract the ever-increasing flow of people from the country into the large towns, where only too many must join the army of the unemployed. Even within a radius of 50 m. of London 700,000 acres of land are unaccounted for in the official agricultural returns. These, for more, are being laid down to be utilized, and it is well worth the consideration of the new Conservators and Commissioners whether the lands remaining on their hands, when buying and breaking up large estates, should not be converted into state forests. Such a measure might become a useful auxiliary in the peaceful settlement of the Irish land question. No doubt success depends upon the probable financial results. There are at present no British statistics to prove such success; hence, by way of illustration, it may be stated what the results have been in the kingdom of Saxony, which, from an industrial point of view, is comparable with England. That country has 432,085 acres of state forests, of which about one-eighth are stocked with broad-leaved species, and seven-eighths with conifers. Some of the forests are situated on low lands, but the bulk of the area is found in the hilly parts of the country up to an elevation of 3000 ft. above the sea. The average price realized of late years per cubic foot of wood amounts to 5d., and yet to such perfection has the management been brought by a well-trained staff, that the mean annual net revenue, after meeting all expenses, comes to 21s. an acre all round. There can be no doubt that, under the more favourable climate of Great Britain, even better results can be obtained, especially if it is remembered that foreign supplies of coniferous timber must fall off, or, at any rate, the price per cubic foot rises considerably.

These things have been recognized to some extent, and a movement has been set on foot to improve matters. The Commissioners of Woods and a number of private proprietors had rational working plans prepared for their forests, and instruction in forestry has been developed. There is now a well-equipped school of forestry connected with the university of Oxford, while Cambridge is following similar lines; instruction in forestry is given at the university of Edinburgh, the Durham College of Science, at Bangor, Cirencester and other places. The Commissioners of Woods have purchased an estate of 12,500 acres in Scotland, which will be converted into a crown forest, so as to serve as an example. The experience thus gained will prove valuable should action ever be taken on the lines suggested by a Royal Commission on Coast Erosion, Reclamation of Tidal Lands and Afforestation, which reported on the last such survey in 1909.

India.—The history of forest administration in India is exceedingly instructive to all who take an interest in the welfare of the British Empire, because it places before the reader an account of the gradual destruction of the greater part of the natural forests, a process through which most other British colonies are now passing, and then it shows how India emerged triumphantly from the self-inflicted calamity. As far as information goes, India was, in the early times, for the most part covered with forest. Subsequently settlers opened out the country along fertile valleys and streams, while nomadic tribes, moving from pasture to pasture, fired alike hills and plains. This process went on for centuries. With the advent of British rule forest destruction became more rapid than ever, owing to the increase of population, extension of cultivation, the multiplication of herds of cattle, and the universal firing of the forests to produce fresh crops of grass. Then railways came, and with their extension the forests suffered anew, partly on account of the increased demand for timber and firewood, and partly on account of the fresh impetus given to cultivation along their routes. Ultimately, when failure to meet the requirements of public works was brought to notice, it was recognized that a grievous mistake had been made in allowing the forests to be recklessly destroyed. Already in the early part of the 19th century sporadic efforts were made to protect the forests in various parts of the country, and these continued intermittently; but the first organized steps were taken about the year 1855, when Lord Dalhousie was governor-general. At that time conservators of forests existed in Bombay, Madras and Burma.
FORESTS AND FORESTRY

Soon afterwards other appointments followed, and in 1864 an organized state department, presided over by the inspector-general of forests, was established. Since then the Indian Forest Department has steadily grown, so that it has now become of considerable importance for the welfare of the people, as well as for the Indian exchequer.

The first duty of the department was to ascertain the position and extent of the remaining forests, and more particularly of that portion which still belonged to the state. Then a special forest law was passed, which was superseded in 1878 by an improved act, providing for the legal formation of permanent state forests; the determination, regulation, and, if necessary, commutation of forest rights; the protection of the forests against unlawful acts and the punishment of forest offences; the protection of forest produce in transit; the constitution of a staff of forest officers, provision to invest them with suitable legal powers, and the determination of their duties and liabilities. The officers who administered the department in its infancy were mostly botanists and military officers. Some of these became excellent foresters. In order to provide a technically trained staff arrangements were made in 1866 by Sir Dielitzen, who was the first inspector-general of forests, for the training of young Englishmen at the French Forest School at Nancy and at similar institutions in Germany. In 1876 the students were concentrated at Nancy, and in 1885 an English forest school for India was organized in connexion with the Royal Indian Engineering College at Cooper's Hill. In 1905 the school was transferred to the university of Oxford. The imperial forest staff of India consisted in 1909 of—officers not specially trained before entering the department, 17; officers trained in France and Germany, 23; officers trained at Cooper's Hill, 143—total 184.

In 1875 a forest school was started at Dehra Dun, United Provinces, for the training of natives of India as executive officers on the provincial staff. Since then a similar school, though on a smaller scale, has been established at Tharrawaddy in Burma. About 500 officers of this class have been appointed. In addition, there are about 11,000 subordinates, foresters and forest guards, who form the protective staff. The school at Dehra Dun has lately been converted into the Imperial Forest College.

The progress made since 1864 is really astonishing. According to the latest available returns, the areas taken under the management of the department are—reserved state forests, or permanent forest estates, 91,772 sq. m.; other state forests, 141,669 sq. m.; or a total of 233,441 sq. m., equal to 24 % of the area over which they are scattered. At present, therefore, the average charge of each member of the controlling staff comprises 1,266 sq. m.; that of each executive officer, 446 sq. m.; and that of each protective official, 21 sq. m. It is the intention to increase the executive and protective staff considerably, in the same degree as the management of the forests becomes more detailed. Of the above-mentioned area the Forest Survey Branch, established in 1872, has up to date surveyed and mapped about 65,000 sq. m. From 1864 onwards efforts were made to introduce systematic management into the forests, based upon working plans, but, as the management had been provincialized, there was no central or continuous control. This was remedied in 1884, when a central Working Plans Office, under the inspector-general of forests, was established. This officer has since then controlled the preparation and execution of the plans, a procedure which has led to most beneficial results. Plans referring to about 38,000 sq. m. are now (1909) in operation, and after a reasonable lapse of time there should not be a single forest of importance which is not worked on a well-regulated plan, and on the principle of a sustained yield. While the danger of overworking the forests is thus being gradually eliminated, their yield capacity is increased by suitable silvicultural treatment and by fire protection. Formerly most of the important forests were annually or periodically devastated by jungle fires, sometimes lighted accidentally, in other cases purposefully. Now 38,000 sq. m. of forest are actually protected against fire by the efforts of the department, and it is the intention gradually to extend protection to all permanent state forests. Grazing of cattle is of great importance in India; at the same time it is liable to interfere seriously with the reproduction of the forests. To meet both requirements careful and minute arrangements have been made, according to which at present 38,000 sq. m. are closed to grazing; 19,000 sq. m. are closed only against the grazing of goats, sheep and camels; while 176,000 sq. m. are open to the grazing of all kinds of cattle. The areas closed in ordinary years form a reserve of fodder in years of drought and scarcity. During famine years they are either opened to grazing, or grass is cut in them and transported to districts where the cattle are in danger of starvation.

The service rendered in this way by a wise forest administration should not be underrated, since one of the most serious calamities of a famine—the want of cattle to cultivate the land—is thus, if not avoided, at any rate considerably reduced. During 1907 the government of India established a Research Institute, with six members engaged in collecting data regarding silviculture, forest botany, forest zoology, forest economics, working plans, and chemistry in connexion with forest produce and production. The institute is likely to lead to further substantial progress in the management of the forests.

The financial results of forest administration in India for the years 1865 to 1905 show the progress made:

The highest percentage of increase occurred in the period 1880–1885. The revenue since 1886 has been considerably increased by the annexation of Upper Burma.

Apart from the net revenue, large quantities of produce are given free of charge, or at reduced rates, to the people of the country. Thus, in the years 1905 and 1906, the net revenue amounted to Rs. 1,956,041, while the produce given free or at reduced rates was valued at Rs. 3,500,661, making a total net benefit derived from the state forests during that year of Rs. 14,562,755, or in round figures one million pounds sterling. The out-turn during the same year amounted to 252 million cub. ft. of timber and fuel and 215 million bamboo. The receipts from the sale of other forest produce came to 9 million rupees, out of a total gross revenue of 24 million rupees.

These results are highly creditable to the government of India, which has led the way towards the introduction of rational forest management into the British empire, thus setting an example which has been followed more or less by various colonies. Even the movement in the United Kingdom during late years is due to it. Apart from India, substantial progress has been made in Cape Colony, Ceylon, the Straits Settlements and the Federated Malay States. Other British colonies are more backward in this respect. Energetic action is urgently wanted, especially in Canada and Australasia, where an enormous state property is threatened by destruction.

UNITED STATES

The Forest Regions.—The great treeless region east of the Rocky Mountains separates the wooded area of the United
FORESTS AND FOREST

States into two grand divisions, which may be called the Eastern and the Western forests. The Eastern forest is characterized by the predominance, on the whole, of broad-leafed trees, the comparative uniformity of its general types over wide areas, and its naturally unbroken distribution. In the Western forest conifers are conspicuously predominant; the individual species reaches enormous and even unequalled dimensions, the forest is frequently interrupted by treeless areas, and the transitions from one type to another are often exceedingly abrupt. Both divisions are botanically and commercially rich in species.

The Eastern forest may conveniently be subdivided into three members:

1. The Northern forest, marked by great density and large volume of standing timber, and a comparative immunity, in its virgin condition, from fire. The characteristic trees are maples, birches and beech (Fagus sylvatica), among the hardwoods and white pine (Pinus strobus), spruce (Picea rubens and Picea mariana) and hemlock (Tsuga heterophylla) among conifers.

2. The Southern forest is on the whole less dense than the Northern, and more frequently burned over. Among its characteristic trees are the longleaf (Pinus palustris) and other pines, oaks, gums, bald cypress (Taxodium distichum) and white cedar (Chamaecyparis thyoides).

3. The Central Hardwood forest, which differs comparatively little from adjacent portions of the Northern and Southern forests except in the absence of conifers. Among its trees are the chestnut (Castanea dentata), hickories, ashes and other hardwoods already mentioned.

The Western division has two members:

1. The Pacific Coast forest, marked by the great size of its trees and the vast accumulations of merchantable timber. Among its characteristic species are the redwood (Sequoia sempervirens) and the Douglas fir (Pseudotsuga taxifolia), sugar pine (Pinus lambertiana), western hemlock (Tsuga heterophylla), giant arborvitae (Thuja plicata) and Sitka spruce (Picea sitchensis).

2. The Rocky Mountain forest, whose characteristic species are the western yellow pine (Pinus ponderosa), Engelmann spruce (Picea engelmanni) and lodgepole pine (Pinus murrayana). This forest is frequently broken by treeless areas of greater or less extent, especially towards the south, and it suffers greatly from fire. Subarid in character, except to the north and at high elevations, the vast mining interests of the region and its treeless surroundings give this forest an economic value out of proportion to the quantities of timber it contains.

This distribution of the various forests is indicated on the first of the two accompanying maps. The second map shows the situation of the national forests hereafter mentioned.

The forests of Alaska fall into two main divisions: the commercial though undeveloped forests of the south-east coast, which occur along the streams and on the lower slopes of the mountains and consist chiefly of western hemlock (Tsuga heterophylla), Sitka spruce (Picea sitchensis), yellow cedar (Chamaecyparis nootkatensis) and giant arborvitae (Thuja plicata), usually of large size and uninjured by fire; and the vast interior forests, swept by severe fires, and consisting chiefly of white and black spruces (Picea canadensis and nigra), paper birch (Betula papyrifera) and aspen (Populus tremuloides), all of small size but of great importance in connection with mining. Northern Alaska and the extreme western coast regions are entirely barren.

The National Forest Policy.—The forest policy of the United States may be said to have had its origin in 1799 in the enactment of a law which authorized the purchase of timber suitable for the use of the navy, or of land upon which such timber was growing. It is true that laws were in force under the early governments of Massachusetts, New Jersey and other colonies, providing for the care and protection of forest interests in various ways, but these laws were distinctly survivals of tendencies acquired in Europe, and for the most part of little use. It was not until the apparent approach of a dangerous shortage in certain timber supplies that the first real step in forest policy was taken by the United States. Successive laws passed from 1817 to 1831 strove to give larger effect to the original enactment, but without permanent influence towards the preservation of the live oak (Quercus virginiana Mill.), which was the object in view. A long period of inaction followed these early measures. In
1831 the solicitor of the treasury assumed a partial responsibility for the care and protection of the public timber lands, and in 1853 this duty was transferred to the commissioner of the general land office in the Department of the Interior. The effect of these changes upon forest protection was unimportant. When, however, at the close of the Civil War railway building in the United States took on an unparalleled activity, the destruction of forests by fire and the axe increased in a corresponding ratio, and public sentiment began to take alarm. Action by several of the states slightly preceded that of the Federal government, but in 1876 Congress, acting under the inspiration of a memorial from the American Association for the Advancement of Science, authorized the appointment of an officer (Dr Franklin B. Hough) under the commissioner of agriculture, to collect and distribute information upon forest matters. His office became in 1880 the division of forestry in what is now the United States Department of Agriculture.

As the railways advanced into the treeless interior, public interest in tree-planting became keen. In 1873 Congress passed and later amended and repealed the timber culture acts, which granted homesteads on the treeless public lands to settlers who planted one-fourth of their entries with trees. Though these measures were not successful in themselves they directed attention towards forestry. The act which repealed them in 1891 contained a clause which lies at the foundation of the present forest policy of the United States. It provided that the president, at his discretion, could set aside a certain portion of public lands wholly or in part covered with timber or undergrowth, whether of commercial value or not, as public reservations, and the President should, by public proclamation, declare the establishment of such reservations and the limits thereof. Some eighteen million acres had been proclaimed as reservations at the time when, in 1896, the National Academy of Sciences was asked by the secretary of the interior to make an investigation and report upon the inauguration of a rational forest policy for the forest lands of the United States. Upon the recommendation of a commission named by the Academy, President Cleveland established more than twenty-one million acres of new reserves on the 22nd of February 1897. His action was widely misunderstood and attacked, but it awakened a public interest in forest questions without which the rapid progress of forestry in the United States since that time could never have been made.

Within a few months after the proclamation of the Cleveland reserve the present national forest policy took definite shape. Under this policy the national government holds and manages the public lands, and the right to extract the timber or minerals or other objects of value has been vested by presidential proclamation in accordance with the act of 1891. These lands are held against private acquisition under the Homestead Act (except as to agricultural lands as hereafter mentioned), the Timber and Stone Act, and other laws under which the United States disposes of its unappropriated public domain, but not against private acquisition under the Mineral Land Laws. They are selected from lands believed to be more valuable for forest purposes than for agriculture, and are managed with the purpose of securing from them the best and largest possible returns of timber, and with due regard to the preservation of undergrowth, for irrigation or power, of timber, or forage for stock, or of any other beneficial product. The aggregate area of the reserves, or national forests, has been steadily increased until they now include nearly all the timber lands left of the public domain.

The general lines of this policy were in part laid down by the commission already mentioned, in its report submitted to the secretary of the interior, May 1, 1897, and by the act of June 4, 1897, which was largely shaped by the work of the commission. Until this act, the lands of the national forests had been in theory closed against any form of use; nor had the possibility of securing forest preservation by wise use received much thought from those who had favoured their creation. Such a state of affairs could not continue. Before long public opinion would have forced the opening to use of the resources thus arbitrarily locked up, and in the absence of any administrative system providing for conservative use, the national forests would inevitably have been abolished, and the whole policy of government forest holdings would have ceased. The act of June 4, 1897 was therefore of the first importance. This act conferred upon the secretary of the interior general powers for the proper management of the national forests through the general land office of his department. It provided for the designation and sale of dead, mature and large timber; authorized the secretary to permit free use of timber in small quantities by settlers, miners and residents; empowered him to "make such rules and regulations and establish such service as will insure the objects of such reservations, namely, to regulate their occupancy and use and to preserve the forests thereon from destruction"; and made violation of the act or of such rules and regulations a misdemeanor. The statute limited the power to establish forest reservations to the purpose of improving and protecting the forest, securing favourable conditions of water flows, and furnishing a continuous supply of timber for the use and necessities of citizens of the United States. Lands found, upon due examination, to be more valuable for other purposes than for forest uses might be eliminated from any reservation, and all mineral lands within the reservations were left open to private appropriation under the mineral laws. The rights of settlers and claimants were safeguarded, and civil and criminal jurisdiction, except so far as the punishment of offences against the United States in the reservations was concerned, was reserved to the States.

The Forest Service, as originally constituted, was entrusted to the general land office, the same act assigned the surveying and mapping of them to the United States Geological Survey, which has published descriptions and maps of some of the more important.

No attempt was made in the general land office to develop a technical forest service. There were, indeed, at the time of the passage of the act, less than ten trained foresters in the United States, no means of training more, and very little conception of what forestry actually meant. The purpose of the administration was therefore mainly protection against trespass and fire, particularly the latter. Regulations were made giving effect to the provisions of the act of June 4, set forth above, but in the absence of technical knowledge as to what might safely be done, the tendency was rather to restrict than to extend the use of the forest. Meanwhile, however, there was rapidly developing in another branch of the government service an organization qualified for actual forest management.

One year after the passage of the act of June 4, 1897, the division of forestry in the Department of Agriculture ceased to be merely a bureau of administration and became an independent agency for introducing the actual practice of forestry among private owners and for conducting the investigations upon which a sound American forest practice could be based. The work awakened great interest among forest owners, and exerted a powerful educational influence upon the country at large. The division extended its work and became (July 1, 1901) the Bureau of Forestry. It drew into its employment for a time nearly all the men who were preparing themselves in increasing numbers (at first abroad, then in the newly-founded schools in the United States) to become foresters. For the first time the profession was recognized as qualified to speak authoritatively on technical questions connected with the administration of the national forests. This led to a request from the secretary of the interior for the advice of the bureau on such questions. Working plans were accordingly undertaken for a number of the forests. The general land office, however, was not ready to attempt active forest management. Though some timber was sold and the grazing of stock regulated to some extent, the main object of the land office administration continued to be protection against fire.

The disadvantages of dispersal of the Federal government forest work among three separate agencies grew more and more apparent, until, on the 1st of February 1905, control of the 63,000,000 acres of forest reserves which up to that time had been set aside was transferred from the general land office to
the Bureau of Forestry. In recognition of its new duties the designation of the bureau became the Forest Service.

Other provisions of the act which affected the transfer were that forest supervisors and rangers should be selected, so far as possible, from qualified citizens of the state or territory in which each forest was situated, and that all money received from the sale of any products or the use of any land or resources of the national forests should be covered into the treasury and constitute a special fund for their protection, administration, improvement and extension. Five days later a statute gave forest officers the power to arrest trespassers; and on the 3rd of March the lieu land selection law was repealed. This law had opened the way for grave abuses through the exchange of worthless land by private owners within the forests for an equal area of valuable timber lands outside.

The law has been modified since by the change of the old name "Forest Reserves" to "National Forests." The act of June 11, 1906, opened to homestead entry lands within national forests found by examination to be chiefly valuable for agriculture. The administration and improvement of the national forests are now provided for directly by congressional appropriation. The power to create national forests conferred on the president by the act of March 1891 has been repealed for the states of Washington, Oregon, Idaho, Montana, Wyoming and Colorado, but for no others.

The Forest Service began in earnest the development of all the resources of the national forests. Mature timber was sold wherever there was a demand for it and the permanent welfare of the forests and protection of the streams permitted, but always so as to prevent waste, guard against fire, protect young growth and ensure reproduction. Regulations were adopted which allowed small sales to be made without formality or delay, secured for the government the full value of timber sold, and eliminated unnecessary routine. Care was taken to safeguard the interests of the government and provide for the maintenance of good technical standards. The conduct of local business was entrusted to local officers. Large transactions with general policies were controlled from Washington, but with careful
provision for first-hand knowledge and close touch with the work in the field. Business efficiency and the convenience of the public were carefully studied. In short, an organization was created capable of handling safely, speedily and satisfactorily the complex business of making useful a forest property of vast extent, scattered through sixteen different states of an aggregate area of over 1,500,000 sq. m. and with a population of 9,000,000.

The growth since the 1st of July 1897 of the area of the national forests, of the expenditures of the government for forestry, and of the receipts from the national forests, is shown by the statement which follows. Though the act of June 4, 1897, became effective immediately upon its passage, the fiscal year 1898 was the first of actual administration, because the first for which Congress made the appropriation necessary to carry out the law.

Until 1906, the sole source of receipts was the sale of timber. In the fiscal year 1907, however, timber sales furnished less than half the receipts. The following statement concerning the timber sales of the fiscal years 1904–1907 will serve to bring out the change that followed the transfer of control to the forest service in the midst of the fiscal year 1905:

These figures show (1) a large excess each year in the amount of timber sold over that cut and paid for; (2) nine times as much timber sold at the end of the four-year period as at the beginning and three times as much cut; and (3) a much higher price obtained per thousand board-feet at the end of the period than at the beginning. Each of these matters calls for comment. The sales are of stumpage only; the government does no logging on its own account.

1. More timber is sold each year than is cut and paid for, because many of the sales extend over several years. With increasing sales the amount sold each year for future removal has exceeded the amount to be removed during that year under sales of earlier years. Large sales covering a term of years are made because the national forests contain much overmature timber, which needs removal, but which is frequently too inaccessible to be saleable in small amounts. To prevent speculation the time allowed for cutting is never more than five years, and cutting must begin at once and be continued steadily.

2. The volume of sales has increased rapidly because much forest is ripe for the axe, the demand is strong, and control by trained men makes it safe to cut more freely. The increase is marked both in small and in large sales, but a score of sales for less than $500 are made against one for more. The total cut is still far below the annual increment of the forests. As the demand grows restrictions must increase in order to husband the present supply until the next crop matures.

3. The stumpage price would seem on the face of the figures to have risen from about one dollar to more than three dollars per thousand board-feet. The receipts, however, for any one year are not exclusively for the timber cut in that year, since payments are made in advance. In the year 1907 the average price obtained was something less than $2.50 per thousand. It is therefore true that stumpage prices have risen greatly, although conditions new to the American lumbermen are imposed. Full utilization of all merchantable material, care of young growth in felling and logging, and the piling of brush, to be subsequently burned by the forest officers if burning is necessary, are among these conditions. Timber to be cut must first be marked by the forest officers. Sales of more than $100 in value are made only after public advertisement.

Only the simplest forms of silviculture have as yet been introduced. The vast area of the national forests, the comparatively sparse population of the West, the rough and broken character of the forests themselves, and the newness of the problems which their management presents, make the general application of intensive methods for the present impracticable. Natural reproduction is secured. The selection system is most used, often under the rough and ready method of an approximate diameter limit, with the reservation of seed trees where needed. The tendency, however, is strongly towards a more flexible and effective application of the selection principle, as a better trained field force is developed and as market conditions improve.

One conspicuous achievement was the reduction of loss by fires on the national forests. During the unusually dry season of 1905 there were only eight fires of any importance, and the area burned over amounted only to about .16 of 1% of the total area. In 1906 about .12 of 1% was burned. This was accomplished by efficient patrol, co-operation of the public, and by preventive measures, such as piling and burning the brush on cut-over areas.

Since the beginning of 1906 the largest source of income from the national forests was their use for grazing. Stock-raising is one of the most important industries of the West. Formerly cattle and sheep grazed freely on all parts of the public domain. In the early days of the national forests the wisdom of permitting any grazing at all upon them was sharply questioned. Unrestricted grazing had led to friction between individuals, the deterioration of much of the range through overstocking, and serious injury to the forests and stream flow. The forests of the West, however, are largely of open growth and contain many grassy parks, the results of old fires, and many high mountain meadows. Under proper regulations the grass and
other forage plants which they produce in great quantity can be used without detriment to the forests themselves, and with great benefit to the stock industry, which often can find summer pasturage nowhere else. Except in southern California grazing is now permitted on all national forests unless the watersheds furnish water for domestic use; but the time of entering and leaving, the number of head to be grazed by each applicant, and the part of the range to be occupied are carefully prescribed. Planted areas and cut-over areas are closed to stock until the young growth is safe from harm, and goats are allowed only in the brushland of the foothills.

The results of regulation, in addition to the protection of forest growth and streams, are the prevention of disputes, improved range, better stock, stable conditions in the stock industry, and the better use of the land for the interest of progress and development. The first right to graze stock on the forests is given to residents, small owners and those who have used the range before. Thus the crowding out of the weaker by the stronger and of the settler by the roving outsider has been stopped. In 1906 the forest service began to impose a moderate charge for the use of the national forest range. The following statement shows the amount of stock grazed on the national forests 1904-09, and the receipts for the grazing charge:

A work of enormous magnitude which has now begun is planting on the national forests. At present, with low stumpage prices and incomplete utilization of forest products, clear cutting with subsequent planting is not practicable. There are, however, many million acres of denuded land within the national forests which require planting. Such planting is still confined chiefly to watersheds which supply cities and towns with water. The first planting was done in 1892, in California. Since then similar work has been done on city watersheds in Colorado, Utah, Idaho and New Mexico. Other plantations are in the Black Hills national forest, where large areas of cut-over and burned-over land are entirely without seed trees, and in the sandhill region of Nebraska. Up to 1908 about 2,000,000 seedlings had been planted, on over 2000 acres—a small beginning, but the work was entirely new and presented many hard problems.

The nursery operations of the forest service are concentrated at seven stations, located in southern California, Nebraska, Colorado, New Mexico (2), Utah and Idaho, where stock is raised for local planting and for shipment elsewhere. These nurseries are small. Their annual productive capacity is between 8,000,000 and 10,000,000 seedlings. Each nursery is practically an experimental forest-planting station, at which a large variety of species are grown and various methods are tried.

The organization of the administrative work of the national forests is by single forests. On the 1st of January 1908 the total number of forests was 165 with a total area of 162,023,190 acres (on April 7, 1909, the numbers were 146 national forests in the U.S. with 167,672,267 acres, besides two in Alaska with 26,761,626 and one in Porto Rico with 65,950 acres). In charge of each forest is a forest supervisor. Under the supervisors are forest rangers and forest guards, whose duties include patrol, marking timber and scaling logs, enforcing the regulations and conducting some of the minor business arising from the use of the forests. Guards are temporary employees; rangers are employed by the year. The supervisors report directly to and receive instructions from the central office at Washington. In this office there are four branches—operation, grazing, silviculture and products—each of which directs that part of the work which belongs to it, dealing directly with the supervisor. For inspection purposes, however, the forests are separated into six districts, in each of which is located a chief inspector with a corps of assistants. The inspectors are without administrative authority, but assist by their counsel the supervisors, and through inspection reports keep the Washington office informed of the condition of all lines of administrative work in progress. Administrative officers alternate frequently between field and office duties.

The number of forest officers in the several grades on the 1st of January 1908 were: 6 chief inspectors, 26 inspectors, 106 forest supervisors, 41 deputy forest supervisors, 820 forest rangers and 283 forest guards. The total number of employes of the forest service on the same date, including the clerical force, was 2634.

Besides the administration of the national forests, the forest service conducts general scientific researches, extends educational work, and co-operates with private owners who contemplate forest management upon their own tracts. This last work is undertaken because of the need of bringing forestry into practice, the lack of trained foresters outside of the employ of the government, and the lack of knowledge of how to apply forestry and what returns may be obtained. Co-operation takes the form of advice upon the ground and, on occasion, of the making of working plans. The educational work of the service is performed chiefly through publications, the purpose of which is to spread very widely a knowledge of the importance of forestry to the nation and of the principles upon which its practice rests.

The investigations which the service conducts extend from studies of the natural distribution and classification of American forests and of their varied silvicultural problems to statistics of lumber production and laboratory researches which bear upon the economical utilization of forest products. As examples of these researches may be mentioned tests of the strength of timber, studies of the preservative treatment of wood for various uses, wood-pulp investigations and studies in wood chemistry.

Forest Instruction.—Most of the men now in the forest service received their training in the United States. There are several professional schools of forestry. The Yale Forest School, which was opened as a department of Yale University in September 1900, offers a two-years' graduate course with abundant field work, and also conducts a summer school of forestry, especially adapted to the training of forest rangers and special students, at Milford, Pennsylvania. The university of Michigan and Harvard University also offer a two-years' graduate course in forestry. The Pennsylvania State College has recently established a four-years' course in forestry. The full-time Forest School in North Carolina, the oldest of all these schools, offers a one-year course in technical forestry. A large number of the agricultural colleges give instruction in forestry. Among these are Nebraska, Minnesota, Maine, Michigan, Washington and Mississippi agricultural colleges, the university of Georgia and Iowa State College. Berea College, Kentucky, deserves special mention as a college which has done valuable work in teaching forestry without attempting to turn out professional foresters.

Forestry among the States.—Among the states forestry has hardly reached the stage of practical application on the ground. New York holds 1,500,000 acres of forest land. It has a commission to care for its forest preserve, and to protect the forest land throughout the state from fire. The constitution of the state, however, prohibits the cutting of timber on state land, and thus confines the work entirely to protection of the forest and to the planting of waste areas. Pennsylvania is at present showing the most efficient activity in working out a forest policy. It has state forests of 520,000 acres, a good fire law more and more satisfactorily enforced, and eight nurseries for growing planting stock. In 1906 136,000,000 pine seedlings were set out. It has also a school for forest rangers, to be employed on the state forests, and it has just established a state professional school of forestry.

Twenty-six of the states have regularly appointed forest officers, six have carried on studies of forest conditions in co-operation with the forest service, and there is scarcely one which is not actively interested in forestry. Laws, generally good, to prevent damage from forest fires, have been enacted by practically all
the states, but their enforcement has unfortunately been lax. Public sentiment, however, is making rapid progress. Among the best laws are those of Maine, New Hampshire, Minnesota, New York, Pennsylvania and Wisconsin. The New York law, for example, provides for the appointment of one or more firewardens in each town of the counties in which damage by fire is especially to be feared. In other counties supervisors of towns are ex-officio firewardens. A chief firewarden has general supervision of their work. The firewarden, half of the cost of whose services is paid by the state, receive compensation only for the time actually employed in fighting fires. They may command the service of any citizen to assist them. Setting fire to woods or waste lands belonging to the state or to another, if such fire results in loss, is punishable by a fine not exceeding $250 or imprisonment not exceeding one year, or both, and damages are provided for the person injured. Since fire is beyond question the most dangerous enemy of forests in the United States, the measures taken against it are of vital importance.

The following table shows the amount of forest land held by the different states, and by the territory of Hawaii—

**Forestry on Private Lands.**—The practice of forestry among private owners is of old date. One of the earliest instances was that of Jared Eliot, who, in 1736, began the systematic cutting of timber land to supply charcoal for an iron furnace at Old Salisbury, Connecticut. The successful planting of waste lands with timber trees in Massachusetts dates from about ten years later. But such examples were comparatively rare until recent times. At present the intelligent harvesting of timber with a view to successive crops, which is forestry, is much more common than is usually supposed. Among farmers it is especially frequent. It was begun among lumbermen by the late E. S. Cole, of Bangor, Maine, who made a practice of restricting the cut of spruce from his forests to trees 12 or sometimes even 14 in. in diameter, with the result that much of his land yielded, during his life, a second crop as plentiful as the first. Many owners of spruce lands have followed his example, but until very recently without improving upon it. Systematic forestry on a large scale among lumbermen was begun in the Adirondacks during the summer of 1898 on the lands of Dr. W. S. Webb and Hon. W. C. Whitney, of a combined area of over 100,000 acres, under the superintendence of the then Division of Forestry. In these forests spruce, maple, beech and birch predominate, but the spruce alone is at present of the first commercial importance. The treatment is a form of the selection system. Under it a second crop of equal yield would be ripe for the axe in thirty-five years. Spruce and pine are the only trees cut. The work had been so far up to 1902, with great satisfaction to the owners and the lumbering contractors, as well as to the decided benefit of the forest. The lumbering is regulated by the following rules, and competent inspectors are employed to see that they are rightly carried out: (1) No trees shall be cut which are not marked. (2) All trees marked shall be cut. (3) No trees shall be left lodged in the woods, and none shall be overlooked by the skidders or haulers. (4) All merchantable logs which are as large as 6 in. in diameter at the small end must be utilized. (5) No stumps shall be cut more than 6 in. in width where the stump is wider. (6) No spruce shall be used for bridges, corduroy, skids, slides, or for any purpose except building camps, damms or booms, unless it is absolutely necessary on account of lack of other timber. (7) All merchantable spruce used for skidways must be cut into logs and hauled out. (8) Contractors must not do any unnecessary damage to young growth in lumbering; and if any is done, they must discharge the men who did it.

These two instances of forestry have been most useful and effective among lumbermen and other owners of forest land in the north-east. Among those who have followed their example are the Berlin Mills Paper Company in northern New Hampshire, the Cleveland and Edinboro Paper Company in northern Michigan, and the Delaware and Hudson Railroad Company in New York, all of which have employed professional foresters. The most notable instance of forestry in the south is on the estate of George W. Vanderbilt at Black Mountain, N.C. This was the first case of systematic forestry under regular working plans in the United States. It was begun in 1897 on about 4000 acres, and has since been extended until it covers about 100,000 acres. A professional forester with a corps of trained rangers under him is in charge of the work. The Pennsylvania Railroad has recently employed a trained forester and several assistants and has undertaken systematic forestry on a large scale.

The effect of the work of the forest service in assisting private owners is evidenced by the fact that down to the year 1908 670 wood lots and timber tracts had been examined by agents of the forest service, of which 250 were tracts over 400 acres in extent, and planting plans had been made for 436 owners covering a total area of 80,000 acres. Expert advice is also given to wood lot owners upon application by many of the state foresters.

**The American Practice.**—The conditions under which forestry is practiced in Europe and in America differ so widely that rules which are received as axiomatic in the one must often be rejected in the other. Among these conditions in America are the highly developed and specialized methods and machinery of lumbering, the greater facilities for transportation and consequent greater mobility of the lumber trade, the vast number of small holdings of forest land, and the enormous supply of low-grade wood in the timbered regions. High taxes on forest properties, cut-over as well as virgin, notably in the north-western pines, and the firmly established habits of lumbermen, are factors of great importance. From these and other considerations it follows that such generally accepted essentials of European methods of forestry as a sustained annual yield, a permanent force of forest labourers, a permanent road system and the like, are in most cases utterly inapplicable in the United States at the present day in private forestry. Methods of forest management, to find acceptance, must there conform as closely as possible to existing methods of lumbering. Rules of marked simplicity, the observance of which will yet secure the safety of the forest, must open the way for more refined methods in the future. For forestry is at present a perishable commodity, with a limited market, constantly changing crews, and an almost total ignorance of the silvics of all but a few of the most important trees—all combine to enforce the simplest silvicultural treatment and the utmost concentration of purpose on the two main objects of forestry, which are the production of a net revenue and the perpetuation of the forest. Such concentration has been followed in practice by complete success.

The forests which with the American forester deals are rich in species usually ended, with abundant powers of reproduction, and, over a large part of their range, greatly dependent for their composition and general character upon the action of forest fires. Of the commercially valuable trees there may be said to be, in round numbers, a hundred out of a total forest flora of about 500 species, but many trees not yet of importance in the lumber trade will become so hereafter, as has already happened in many cases. The attention of the forester must usually be concentrated upon the growth and reproduction of a single species, and never of more than a very few. Thus the silvicultural problems which must be solved in the practice of forestry in America are fortunately less complicated than the presence of so many kinds of trees in forests of such diverse types would naturally seem to indicate.

The forest fire problem is one of the most difficult with which the American forester has to deal. It is probable that forest
forests have had more to do with the character and distribution of forests in America than any other factor except rainfall. With an area range over thousands of square miles, in many portions of the United States they occur regularly year after year on the same ground. Trees whose thick bark or abundant seeding gives them peculiar powers of resistance, frequently owe their exclusive possession of vast areas purely to the action of fire. On the economic side fire is equally influential. The probability, or often the practical certainty, of fire after the first cut, commonly determines lumbermen to leave no merchantable tree standing. Forest fires are thus the most effective barriers to the introduction of forestry. Excessive taxation of timber land is another of almost equal effect. Because of it lumbermen hasten to cut, and afterwards often to abandon, lands which they cannot afford to hold. This evil, which only the progress of public sentiment can control, is especially prevalent in certain portions of the white pine belt.

Forest Associations.—Public sentiment in favour of the protection of forests is now widespread and increasingly effective throughout the United States. As the general understanding of the objects and methods of forestry becomes clearer, the tendency, hitherto very marked, to confound ornamental tree planting and botanical matters with forestry proper is rapidly growing less. At the same time, the number and activity of associations dealing with forest matters is increasing with notable rapidity. There are now about thirty such associations in the United States. One of these, the Society of American Foresters, is composed exclusively of professional foresters. The American Forestry Association is the oldest and largest. It has been influential in preparing the ground work of popular interest in forestry, and especially in advocating and securing the adoption of the federal forest reservation policy, the most important step yet taken by the national government. It publishes as its organ a monthly magazine called Forestry and Irrigation. The Pennsylvania Forestry Association has been instrumental in placing that state in the forefront of forest progress. Its organ is a bi-monthly publication called Forest Leaves. Other states which have associations or societies of special influence in forest matters are California, Massachusetts, Minnesota, Colorado, New Hampshire, Georgia and Oregon. Arbor Day, instituted in Nebraska in 1872 as a day for shade-tree planting by farmers who had settled on the treeless prairies, has been taken up as a means of interesting school children in the planting of trees, and has spread until it is now observed in every state and territory. It continues to serve an admirable purpose.

Lumbering.—According to the census report for 1905 the capital invested in logging operations in the United States was $90,454,596, the number of employes engaged 146,596, and their wages $66,990,000; sawmills represented an invested capital of $38,021,000, and employed 223,674 persons, whose wages were $100,311,000, while planing mills represented a capital of $222,204,000 and employed 152,030 persons whose wages were $66,434,000.

The operations of the lumber trade in the United States are controlled, and to no small degree determined, by the peculiar unit of measure which has been adopted. This unit, the board-foot, is generally defined as a board one foot long, one foot wide and one inch thick, but in reality it is equivalent to 144 cub. in. of manufactured lumber in any form. To purchase logs by this measure one must first know about what each log will yield in one-inch boards. For this purpose a scale or table is used, which gives the contents of logs of various diameters and lengths in board feet. Under such a standard the purchaser pays for nothing but the saleable lumber in each log, the inevitable waste in slabs and sawdust costing him nothing.

The table at foot gives the estimated consumption of wood for certain purposes in the United States in 1906.

In addition to this amount, an immense quantity of wood is used each year for fuel, posts and other domestic purposes, and the total annual consumption is not less than 20 billion cub. ft.

The years 1890 to 1906 were marked by rapid changes in the rank of the important timber trees with reference to the amount of timber cut, and a shifting of the important centres of production. Among coniferous trees, white pine has yielded successively to yellow pine and Douglas fir, while the scene of greatest activity has shifted from the Northern forest to the Southern, and from there is rapidly shifting to the Pacific Coast. The total cut of coniferous lumber has increased steadily, but that of the hardwoods is falling off, and in 1906 it was 15% less than in 1899, while interior hardwoods are gradually assuming more and more importance, and the scene of greatest activity has passed from the middle west to the south and the Appalachian region.

Conifers.—The coniferous supply of the country is derived from four forest regions: (1) The Northern forest; (2) the Southern forest; (3) the Pacific Coast forest; and (4) the Rocky Mountain forest.

1. The Northern forest was long the chief source of the coniferous lumber production in the United States. The principal timber tree of this region is the white pine, usually known in Europe as the Weymouth pine. It has an average height when mature of 110 ft., with a diameter a little less than 3 ft. but the virgin timber is approaching exhaustion. White pine was one of the first trees to be cut extensively in the United States, and Maine, the pine tree state, was at first the centre of production. In 1875 the cut of white pine on the Penobscot river was 144 million ft., that of spruce 14 million and of hemlock 11 million. Thirty years later the pine cut had sunk to 23 million, spruce had risen to 118 million, and hemlock had passed pine by a million feet. Meanwhile, the centre of production had passed from the north woods to the Lake States, and for many years this region was the scene of the most vigorous lumbering activity in the world. The following figures show the cut for the Lake

1889. 15,932,933,000

Second to the white pine among the coniferous lumber trees of the Northern forest is the hemlock (Tsuga canadensis). It is used chiefly for construction purposes and furnishes a comparatively low grade of lumber.

The spruce (Picea rubens) is used chiefly for lumber, but it is in large and increasing demand in the manufacture of paper pulp. For the latter purpose hemlock, poplar (Populus tremuloides and P. grandidentata) and several other woods are also employed, but on a smaller scale. The total consumption of wood for paper in the United States for 1906 was 3,660,000 cords, of which 4,000,000 was spruce. Of this, however, 720,000 cords were imported from Canada.

The chief product of the Southern forest is the yellow pine. This is the collective term for the longleaf, shortleaf, lobolly and Cuban pines. Of these the longleaf pine (Pinus palustris Mill.), called pitch-pine in Europe, is the most important. Its timber is probably superior in strength and durability to that of any other member of the genus Pinus, and in addition to its value as a timber tree it is the source of naval stores in the United States. The average size of the mature longleaf pine is 90 ft. in height and 20 in. in diameter. Shortleaf (Pinus echinata) and lobolly (P. taeda) are other important members of this group. Their wood very closely resembles that of the longleaf pine and is often difficult to distinguish from it. The trees are also of about the same size and height. Lobolly is, however, of more rapid growth. The total cut of yellow pine in 1906 was 11,661,000,000 board ft.; it has perhaps not yet reached its maximum, but is certainly near it.

Another important coniferous tree of the Southern forest is the bald cypress (Taxodium distichum), which grows in the swamps. The cut in 1906 was 89,000,000 board ft., a gain of 55% over 1899.

But the great supply of coniferous timber is now on the Pacific Coast. The Douglas fir (Pseudotsuga taxifolia), also known as Douglas spruce, red fir and Oregon pine, is the foremost tree in Oregon and Washington, and the redwood in California. When mature the Douglas fir averages 200 ft. in height and 4 ft. in diameter, and the redwood 225 ft. in height and 8 ft. in diameter. Other important trees of the Pacific Coast are sugar pine (Pinus lambertiana), western red cedar (Thuja plicata), western larch (Larix occidentalis), Sitka spruce (Picea sitchensis), western hemlock (Tsuga heterophylla) and western yellow pine (Pinus ponderosa). These trees will all be of increasing importance.

Logging on the Pacific Coast is characterized by the use of powerful machinery and by extreme skill in handling enormous weights. This is especially true in California, where the logs of redwood and of the big tree (Sequoia Washingtoniana) are often more than 10 ft. in diameter. Logging is usually done by wire cables operated by donkey-engines. The journey to the mill is usually by rail. The mills are often of great size, built on piles over tidal water and so arranged that their product is delivered directly from the saws and dry kilns to vessels moored alongside. The products of the Pacific Coast forest make their way over land to the markets of the central and eastern states and into foreign markets. Among the lumber-producing states, Washington has in seven years jumped from fifth place to first, and its output has increased from 1,428,000,000 board ft. in 1899 to 4,305,000,000 ft. in 1906. Oregon and California have increased their output from 734,000,000 each in 1899 to 1,665,000,000 and 1,349,000,000 respectively in 1906. Of the total output of these three states (7,294,000,000 ft.) 4,868,000,000 ft. is Douglas fir and 666,000,000 redwood.

4. The important lumber trees of the Rocky Mountain region are the western yellow pine, the lodgepole pine, the Douglas fir and the Engelmann spruce. The Douglas fir, here extremely variable in size and value, reaches in this region average dimensions of perhaps 80 ft. in height by 2 ft. in diameter, the western yellow pine 90 ft. by 3 ft. and the Engelmann spruce 60 ft. by 2 ft. Mining, railroad and domestic uses chiefly absorb the annual timber product, which is considerable in quantity, and of vast importance to the local population. The lumber output of the Rocky Mountain region is, however, increasing very rapidly both in the north and in the south-west. One of the largest mills in the United States is in Idaho.

The following table summarizes the cut of the important coniferous species during the years 1899-1906:

*Not separately reported.*

Oak, which in 1899 furnished over half the entire output, has fallen off 36.5%. Yellow poplar, which in 1899 was second among the hardwoods, has fallen off 38.3%, and now occupies third place; and elm, the great stand-by in slack cooperage, has fallen 59.8%. On the other hand less valuable species like maple and red gum have advanced 39 and 39% respectively.

The decrease is largely due to the fact that the hardwoods grow naturally on the better classes of soil, and in the eastern
FOREY—FORFARSHIRE

United States where the population has always been the densest, and as a consequence of this, a large proportion of the original hardwood forests have been cleaned up and put under cultivation. The hardwood supply of the future must be obtained chiefly from the Appalachian region, where the conditions are less favourable to agriculture.

In addition to the lumber cut, enormous quantities of hardwoods are used each year for railroad ties, telephone and other poles, piles, fence posts and fuel, and there is a great amount of waste in the course of lumbering and manufacture.

AUTHORS.—Sargent, Silva of North America (Boston, 1891-1897); Manual of Trees of North America (Boston, 1903); Lemmon, Handbook of Western American Cone-Bearers (San Francisco, 1895); Brummen, North American Forests and Forestry (New York, 1900); Fernow, Economic Botany (New York, 1902); Sullivan, Timber and Black Spruce (New York, 1898); Finchot and Graves, The White Pine (New York, 1896). See also the various publications of the U.S. forest service, including especially the following general works: Forest Influences: Forester of Forestry; the Timber Supply of the United States; the Warming Hardwood Supply; Forest Products of the United States in 1906; Exports and Imports of Forest Products in 1906; Federal and State Forest Laws; Regulations and Instructions for the Use of the National Forests; also part v. of the Nineteenth and of the Twenty-first Annual Reports of the United States Geological Survey, and vol. ix. of the 20th Census Reports.

Hardwood forests. The hardwoods, like the conifers, are divided into two great families: the oak family, which includes the elms, ashes, maples, beeches, etc.; and the mountain family, which includes the birches, willows, etc.

castle on one of his incursions, but in 1307 Robert Bruce seized
it, put its defenders to the sword and then destroyed it, its site
being now marked by the town cross. Previous to the reign
of James VI. the weekly market was held on Sunday, but
after the union of the crowns parliament enacted that it should
be held on Friday. The town sided with Charles I. during
the Civil War, and Charles II. presented the Cross to it out of
regard for the loyalty shown to his father. Forfar seems to have
played a less reputable part in the persecution of witches. In
1661 a crown commission was issued for the trial of certain miserable
creatures one of whom bore the name of Tannadice. In the
same year one John Ford for his services as a witch-finder was
admitted a burgess along with Lord Kinghorn. The witches
bride, a gog to prevent them from speaking whilst being led to
execution, is still preserved in the county hall. One mile to the
E. lie the ruins of Restennet Priory, where a son of Robert
Bruce was buried. For twenty years after the Reformation
it was used as the parish church and afterwards by the Episco-
palians, until they obtained a chapel of their own in 1582.

FORFARSHIRE, or Angus, an eastern county of Scotland, bound
ed N. by the shires of Kinardine and Aberdeen, W. by Per-
thabie, S. by the Firth of Tay and E. by the North Sea.
It has an area of 550,171 acres, or 873-7 sq. m. The island
of Rossie and the Bell Rock belong to the shire.

Forfarshire is characterized by great variety of surface and
may be divided physically into four well-marked sections.
In the most northerly of these many of the rugged masses of
the Grampians are found; this belt is succeeded by Strathmore,
or the Howe of Angus, a fertile valley, from 6 to 8 m. broad,
which is a continuation of the Howe of the Mearns, and runs
south-westwards till it enters Stratharn, to the south-west of
Perth; then come the Sidlaw Hills and a number of isolated
heights, which in turn give way to the plain of the coast and the
Firth. The mountains are all in the northern division and belong
to the Binchinahine group (sometimes rather inexactingly called
the Braes of Angus) of the Grampian ranges. Among the highest
masses, most of which lie on or near the confines of the bordering
counties, are Glas Maol (3502 ft.) on the summit of which the
shires of Aberdeen, Forfar and Perth meet, Cairn-na-Grashna (3484),
Faffrine (2747), Broad Cairn (3268), Gear Leachach (3143), Tolmaiour (3143), Tuibide (3140), Driess (3105), Mount Keen (3097) and Mayar (3094), whose peaks of upwards of
2000 ft. are numerous. The Sidlaw Hills—the greater part of
which, however, belongs to Perthshire—are much less lofty and
of less striking appearance. They have a breadth of from
3 to 6 m., the highest points within the county being Craigowl
Hill (1493 ft.), Auchterhouse Hill (1399) and Gallow Hill (1242).
None of the rivers is navigable, and only three are of any
importance. The Isla, rising in Cairn-na-Grashna, flows southwards,
it is joined by the Indeck and many minor streams, and runs
course of 45 m. Its chief tributaries on the right are the Alyth,
Erichat and Lunan, and on the left the Newton, Melgam and
Dean. Near Bridge of Craig is the fall of Reekie Linn (70 ft.),
so named from the fact that when the stream is in flood the spray
rises in a dense cloud like smoke (reek). Near old Airlie Castle
are the cascades called the Slugs of Auchrannie. The North Esk,
formed by the confluence of the Lee and Mark at Invermark,
are a south-easterly course of 28 m. enters the North Sea
m. of N. of Montrose. On the right bank it receives the West
Water and Cruck and on the left the Tarf and Luther. It gives
the title of earl of Northesk to a branch of the Carnegie
family. The South Esk rises in the Grampians near Mount Fafterne and
not far from its source forms the Falls of Bachnagairn; after
flowing towards the south-east, it bends eastwards near Tannadice
and reaches the North Sea at Montrose, the length of its course
being 48 m. Its principal affluents are the Prosen on the right
and the Noran on the left. It supplies the title of earl of Southesk
of the Northesk to another branch of the Carnegies. The lakes are small,
the two largest being the Loch of Forfar and the mooning
Loch Lee (1 m. long by 1 m. wide). Instruther (a circular in shape
and about 2 m. across), to the north of Airlie Castle, supplies
Dundee with drinking water. The gists of the Forfarshire
Grampians are remarkable for their beauty, and several of them for the wealth of their botanical specimens. The largest and finest of them are Glen Isla, in which are the ruins of Port Castle, destroyed by Argyll in 1640, and the earl of Arirlie's shooting-lodge of the Tulchan; Glen Clova, near the entrance to it stands better for cattle, the seat of the earl of Airlie; Glen Esk and Glen Prosen.

Geology.—A great earth fracture traverses this county from near Edzell on the N.E. to Lintrathen Loch on the S.W. Between Cortachy and the south-western boundary this fault runs in Old Red Sandstone, but north-east of that place it forms the junction line of Silurian and Old Red; and in a general way it may be seen that on the N.W. side of the fault the metamorphosed Silurian rocks are found, while the remainder of the county is occupied by the Old Red Sandstone. On the margin of the disturbance the Silurian rocks take on a grey and greenish tinge, the plates of pebbly grit; farther towards the N.W. we find the same rocks metamorphosed into mica schists and gneisses with pebbly quartzites. Rising up through the schists between Carr Bannock and Mount Battock is a great mass of granite. The Old Red Sandstone extends from this county into Perthshire and Kincardineshire; here some 20,000 ft. of these deposits are seen; an important part being formed of volcanic tufts and lavas which are regularly interbedded in the sandstones and conglomerates. North of Dundee some of the lower beds are traversed by intrusive dolerites, and Dundee Lawis probably the remains of an old vent through which some of the contemporaneous rocks were discharged. The Old Red Sandstone is also subjected to a good deal of folding, as may be seen along the coast. The principal direction of strike is from N.E. to S.W. A synclinal fold occupies Strathmore and between it and a back-throw of the northern extension of the Sidlaw Hills is an antclinal fold. Two fish-bearing beds occur in the county; from the lower one many large Eurypterus have been obtained. The well-known paving slates of the Broughty Ferry, and others of the same kind, are likely to be seen in the form of moranic deposits, the most striking of which is the great transverse barrier of Glenairn in the valley of the S. Esk, half a mile in width and 100 ft. high. The same form is found round the coast in the form of raised beaches at 100, 50 and 25 ft. above the present sea-level.

Climate and Agriculture.—On the whole the climate is healthy and favourable to agricultural pursuits. The mean temperature for the year is 47.5° F., for January 38° and for July 59°. The average annual rainfall is 34 in., the coast being considerably drier than the uplands. In the low-lying districts of the south the harvest is nearly as early as it is in the rest of Scotland, but in the north it is often late. The principal wheat districts are Strathmore and the neighbourhood of Dundee and Arbroath; and the yield is well up to the best Scottish average. Barley, an excellent crop for the south of Scotland, is increased by the heavy rainfall, and though still the leading crop, have somewhat declined. Potatoes are mostly grown near the seacoast in the higher ground; turnips also are largely raised. The northern belt, where it is not waste land, has been turned into sheep walks and deer forests. The black-faced sheep are the most common in the mountainous country; cross-bred sheep in the lowlands. Though it is their native county (where they date from 1658), polled Angus are not reared so generally as in the neighbouring shire of Aberdeen, but short horns are a favourite stock and Irish cattle are imported for breeding. Exceeding in the vicinity of the towns there are no dairy farms. Horses are raised successfully, Clydesdales being the commonest breed, but the small native garrons are now little used. Pigs also are reared. Save perhaps in the case of the crofts, or very small holdings of less than 10 acres, farm management is fully abreast of the times.

Other Industries.—The staple industries are the jute and flax manufactures. Their headquarters are in Dundee, but they inshore also at other places. Shipbuilding is carried on at Dundee, Arbroath and Montrose. The manufacture of hemp, country spirit and tobacco manufactures, leather, machinery, soap and chemicals, are all of great and growing value. Sandstone quarries employ many hands and the deep-sea fisheries, of which Montrose is the centre, are of considerable importance. The netting of salmon at the mouth of the North Esk is also a profitable pursuit.

Two railway companies serve the county. The North British, entering from the south by the Tay Bridge, follows the coast north-eastwards, sending off at Montrose a branch to Bervie. The Caledonian runs up Strathmore to Forfar, whence it diverges due east to Guthrie, where it again resumes its north-easterly line to three short branches at Forfar and Montrose; it reaches Dundee from Perth by the shore of the estuary of the Tay, and sends branches from Dundee to Kirriemuir via Monikie and Forfar and to Alyth Junction via Newtyle, while a short line from Dunblane gives it touch with Montrose.

Population and Government.—The population was 279,775 in 1891, and 284,683 in 1901, when 1303 spoke Gaelic and English, and 13 Gaelic only. The chief towns are Arbroath (pop. in 1901, 22,938), Brechin (8941), Broughty Ferry (10,454), Carnoustie (5204), Dundee (166,175), Forfar (11,397), Kirriemuir (4096), Monifieth (2134) and Montrose (12,427). Forfarshire returns one member to Parliament. It is a shire district and there is a resident sheriff-substitute at Dundee and another at Forfar, the county town, and courts are held also at Arbroath. In addition to numerous board schools there are secondary schools at Dundee, Montrose, Arbroath, Brechin, Forfar and Kirriemuir, and technical schools at Dundee and Arbroath. Many of the elementary schools earn grants for higher education. The county council and the Dundee and Arbroath town councils expend the "residue" grant in subsidizing science and art and technical schools and classes, including University College, the textile school, the technical institute, the navigation school and the workshop schools at Dundee, the technical school at Arbroath, besides cookery, dairy, dress-cutting, laundry, plumbing and veterinary science classes at different places.

History.—In the time of the Romans the country now known as Forfarshire was inhabited by Picts, of whose occupation there are evidences in remains of weems, or underground houses. Traces of Roman camps and stone forts are common, and there are vitrified forts at Finhaven, Dumsturdy Moir, the hill of Laws near Monifieth and at other points. Spearheads, battle-ax, sepulchral deposits, Scandinavian bronze pins, and other antiquarian relics testify to periods of storm and stress before the land settled down into order, towards which the Church was a powerful contributor. In the earliest days strife was frequent. The battle in which Agricola defeated Galgacus is supposed to have occurred in the Forfarshire Grampians (A.D. 84); the Northumbrian King Egrith and the Pictish King Burde fought near Dunnichen in 685, the former being slain; conflicts with the Danes took place at Aberlemno and other spots; Elphin king of the Scots was defeated by Aengus in the battle of Liff in 850; at Restennet, about 855, the Picts and Scots had a better encounter. In later times the principal historical events, whether of peace or war, were more immediately connected with burghs than with the county as a whole. There is some doubt whether the county was named Angus, its title for several centuries, after a legendary Scottish prince or from the hill of Angus to the east of the church of Aberlemno. It was early governed by hereditary earls and was made a hereditary sheriffdom by David II. The first earl of Angus (by charter of 1380) was George Douglas, an illegitimate son of the 1st earl, who succeeded by Mary, and the son of this earl, who was successful in the wars of the 14th century, was the hero of the 10th and only duke of Douglas, who was also 13th earl of Angus, in 1761, the earldom merged in the dukedom of Hamilton. Precisely when the shire became known by the name of the county town has not been ascertained, but probably the usage dates from the 16th century. Among old castles are the roofless square tower of Red Castle at the mouth of the Leman; the tower of the castle of Auchinleck; the stronghold of Inverquharity near Kirriemuir; the castle of Finhaven; the two towers of old Edzell Castle; the ruins of Melgund Castle, which are fairly complete; the small castle of Newtyle, and the old square tower and gateway of the castle of Craig. See A. Jervise, Memorials of Angus and Mearns (Edinburgh, 1895); Land of the Lindsays (Edinburgh, 1883); Epitaphs and Inscriptions (Edinburgh, 1879); Earl of Crawford, Lives of the
FORFEITURE—FORGERY

Lindsay (London, 1843); Sir W. Fraser, History of the Carriages (Edinburgh, 1869); A. H. Miller, Historical Castles and Mansions (Paisley, 1890); G. Hay, History of Arbroath (Arbroath, 1870); D. D. Black, History of Brechin (Edinburgh, 1867).

FORFEITURE (from "forfeit," originally an offence, and hence a fine exacted as a penalty for such; derived through the O. Fr. forfait, from the late Lat. foris factum, a trespass, that which is done foris, outside), in English law, the term applied (1) to loss or liability to the loss of property in consequence of an offence or breach of contract; (2) to the property of which the party is deprived.

Under the common law, conviction and attainer on indictment for treason or felony was followed not only by forfeiture of the life of the offender, but also by forfeiture of his lands and goods. In the case of treason all the traitor's lands of whosoever holde were forfeited to the king; in the case of felony (including felle-de-se, or suicide), the felon's lands escheated (exceciderunt) to his immediate lord, subject to the king's right to waste them for a year and a day. This rule did not apply to lands held in gavelkind in the county of Kent. The goods of traitors and felons were forfeited to the king. The desire of the king and his officers to realize the proceeds of these confiscations was one of the chief motives for establishing the courts of the king's justices throughout England; and from time to time conflicts arose from attempts by these justices to extend the law of treason—under which the king levied all the forfeitures—at the expense of felony, in which the lord of the felon benefited by the escheats. As regards theft, the king's rights overrode those of the owner of the stolen property, until, in the reign of Henry VIII, provision was made for restitution of the goods to the owner if he prosecuted the thief to conviction. In Pepys's Diary, 21st of January 1667-1668, will be found an illustration of the working of the old law. We find that on the suicide of his brother-in-law, Pepys at once applied to the king personally and obtained a grant of the brother-in-law's estate in favour of his widow and children should the inquest find a verdict of felle-de-se. It was common practice for persons anticipating conviction for treason or felony to assign all their property to others to avoid the forfeiture; and in some instances the accused refused to plead to the indictment and endured the peine forte et dure, until death supervened, to avoid these consequences of conviction. The royal rights to forfeitures arising within particular areas were frequently granted by charter to corporations, towns or individuals. In 1897 the courts had to interpret such charters granted to the town of Nottingham in 1399 and 1448. All forfeitures and escheats with respect to conviction and attainer for treason and felony were abolished as from the 4th of July 1879, except forfeitures consequent upon the now disused process of outlawry, and the forfeitures included in the penalties of praemunire.

The term "forfeit" is also applied to penalties imposed by statute for acts or omissions which are neither reasonable nor felonious. In such statutes the forfeiture ensues in favour of the crown unless the statute indicates another destination; and unless a particular method of enforcing the forfeiture is indicated it is enforceable as a debt to the crown and has priority as such. The words "forfeit and pay" are often used in imposing a pecuniary penalty for a petty misdemeanour, and where they are used the court dealing with the case must not only convict the offender but adjudicate as to the forfeiture. Statutory forfeitures in some cases extend to specific chattels, e.g. of a British merchant-ship when her character as such is fraudulently dissimulated (Merch. Shipp. Act 1804, ss. 70, 71), or of goods smuggled in contravention of the customs acts or books introduced in violation of the copyright acts. Recognisances are said to be forfeited when the conditions are broken and an order of court is made for their enforcement as a crown debt against the persons bound by them.

The term "forfeit" is now most commonly used with reference to real property, i.e. with reference to the rights of lords of the manor or lessors to determine the estate or interest of a copyholder or lessee for breach of the customary or contractual terms of tenure. It is also applied to express the deprivation of a limited owner of settled property, real or personal, for breach of the conditions by which his rights are limited, e.g. by becoming bankrupt or attempting to charge or alienate his interest. As a general rule, the courts "lean against forfeitures" of this kind; and are astute to defeat the claim of the superior landlord or other person seeking to enforce them. By legislation of 1881 and 1892 there is jurisdiction to grant relief upon terms against the forfeiture of a lease for breach of certain classes of covenant, e.g. to pay rent or to insure.

FORGERY (derived through the French from Latin fabricare, to construct), in English law, "the fraudulent making or alteration of writing or documents..." (Blackstone, 1, 269). "The false making, or making malo animo, of any written instrument for the purpose of fraud or deceit." This definition, it will be seen, comprehends all fraudulent tampering with documents. "Not only the fabrication and false making of the whole of a written instrument, but a fraudulent insertion, alteration or erasure, even of a letter, in any material part of a true instrument whereby a new operation is given to it, will amount to forgery,—and this though it be afterwards executed by another person ignorant of the deceit" (Russell on Crimes and Misdemeanors, vol. ii.). A person who, by making the writing of another, to be entered in a lease, so that it appears to be a lease of the manor of Sale instead of the manor of Dale, is a forger. And when a country banker's note was made payable at the house of a banker in London who failed, it was held to be forgery to alter the name of such London banker to that of another London banker with whom the country banker had subsequendy made his notes payable. As to the fraud, "an intent to defraud is presumed to exist if it appears that at the time when the false document was made there was in existence a specific person, ascertained or unascertained, capable of being defrauded thereby; and this presumption is not rebutted by proof that the offender took or intended to take measures to prevent such person from being defrauded in fact, nor by the fact that he had or thought he had a right to the thing to be obtained by the false document" (Stephen's Digest of the Criminal Law). Thus when a man makes a false acceptance to a bill of exchange, and circulates it, intending to take it up and actually taking it up before it is presented for payment, he is guilty of forgery. Even if it be proved as a matter of fact that no person could be defrauded thereby if the charter (the charter of which B had withdrawn his account), the intent to defraud will be presumed. But it would appear that if A knew that B had withdrawn his account, the absence of fraudulent intention would be inferred. A general intention to cheat the public is not the kind of fraud necessary to constitute forgery. Thus if a quack forges a diploma of the college of surgeons, in order to make people believe that he is a member of that body, he is not guilty of forgery.

The crime of forgery in English law has been from time to time dealt with in an enormous number of statutes. It was first made a statutory offence in 1562, and was punishable by fine, by standing in the pillory, having both ears cut off, the nostrils slit up and seared, the forfeiture of land and perpetual imprisonment. It was made capital, without benefit of clergy in 1634. The most notable cases of those who have suffered the extreme penalty of the law are those of the Rev. Dr W. Dodd in 1777, for forging Lord Chesterfield's name on a bond, and Henry Fauntleroy, a partner in the banking-house of Marsh, Sibbald & Co., for the appropriation by means of forged instruments of money entrusted on the bank, in 1824. "Anthony Hammond, in the title Forgery of his Criminal Code, has enumerated more than 400 statutes which contain provisions against the offence" (Sir J. T. Coleridge's notes to Blackstone). Blackstone notices the increasing severity of the legislature against forgery, and says that "through the number of these general and special provisions there is now hardly a case possible to be conceived wherein forgery that tends to defraud, whether in the name of a real or fictitious person, is not made a capital crime." These acts were consolidated in 1850. The later
FORGET-ME-NOT—FORGING

FORGET-ME-NOT, or Scorpion-Grass (Ger. Vergissmeinnicht, Fr. grémillette, scorpionne), the name popularly applied to the small annual or perennial herbs forming the genus Myosotis of the natural order Boraginaeae, so called from the Greek μύος, a mouse, and ῥηα, a mouse, an ear, on account of the shape of the leaves. The genus is represented in Europe, north Asia, North America and Australia, and in Chinese gardens, by about 200 species, with blue, pink or white flowers, a five- or cleft pendent calyx, a salver- or funnel-shaped corolla, having its mouth closed by five short scales and hard, smooth, shining nutlets. The common or true forget-me-not, M. palustris, is a perennial plant growing to a height of 6 to 18 in., with rootstock creeping, stem clothed with lax spreading hairs, leaves light green, and somewhat shining, buds pink, becoming blue as they expand, and corolla rotative, broad, with retuse lobes and bright blue with a yellow centre. The divisions of the calyx extend only about one-third the length of the corolla, whereas in the other British species of Myosotis it is deeply cleft. The forget-me-not, a favourite with poets, and the symbol of constancy, is a frequent ornament of brooks, rivers and ditches, and, according to an old German tradition, received its name from the last words of a knight who was drowned in the attempt to procure the flower for his lady. It attains its greatest perfection under cultivation, and, as it flowers throughout the summer, is used with good effect for garden borders; a variety, M. striigera, is more hairy and erect, and its flowers are smaller than those of M. palustris. In M. virgo, the petals are yellow when first open and change generally to a dull blue; sometimes they are permanently yellowish-white. Of the species in cultivation, M. dissitiflora, 6 to 8 in., with large handsome abundant sky-blue flowers, is the best and earliest, flowering from February onwards; it does well in light cool soils, preferring peaty ones, and should be renewed annually from seeds or cuttings. M. rupicola, or M. alpestris, 2 to 3 in., intense blue, is a fine rock plant, preferring shady situations and gritty soil; M. azorica (a native of the Azores) with purple, ultimately becoming blue, is a native of Madeira an in choice, has a similar habit but larger flowers; M. sylvatica, 1 ft., blue, pink or white, used for spring bedding, should be sown annually in August.

FORGING, the craft of the smith, or “blacksmith,” exercised on malleable iron and steel, in the production of works of constructive utility and of ornament. It differs from foun ding (q.v.) in the fact that the metal is never melted. It is essentially a moulding process, the iron or steel being worked at a full red, or white, heat when it is in a plastic and more or less pasty condition. Consequently the tools used are in the main counterparts of the shapes desired, and they mould by impact. All the operations of forging may be reduced to a few very simple ones: (1) Reducing or drawing down from a larger to a smaller section (“fullering” and “swaging”); (2) enlargement of a smaller to a larger portion (“ upsetting”); (3) bending, or turning round
to any angle or curvature; (4) uniting one piece of metal to another ("welding"); (5) the formation of holes by punching; and (6) severance, or cutting off. These include all the operations that are done at the anvil. In none of these processes, the last excepted, is the use of a sharp cutting tool involved, and therefore there is no violence done to the fibre of the malleable metal. Nor have the tools of the smith any sharp edges, except the cutting-off tools or "settes." The essential factor of the fact of the metal, which is viscous when at a full red heat, must never be lost sight of; and in forging wrought iron the judgment of the smith must be exercised in arranging the direction of the fibre in a way best calculated to secure maximum strength.

Fullering denotes the preliminary roughing-down of the material between tools having convex edges; swaging, the completion or finishing process between swages, or dies of definite shape, nearly hemispherical in form. When a bar has to be reduced from larger to smaller dimensions, it is laid upon a fuller or round-faced stake, set in the anvil, and, in some cases, on a flat face (fig. 1), and blows are dealt upon that portion of the face which lies exactly opposite with a fullering tool A, grasped by a rather loosely-fitting handle and struck on its head by a sledge. The position of the piece of work is quickly changed at brief intervals in order to bring successive portions under the action of the swages until the reduction is completed; the upper face, and if a bottle effect is desired, a sledge. The position of the piece of work is quickly changed at brief intervals in order to bring successive portions under the action of the swages until the reduction is completed; the upper face, and if a bottle effect is desired, a fuller is used the under face also, is thus left corrugated slightly. These corrugations are then removed either by a flatter, if the surfaces are plane (fig. 2), or by hollow swages, if the cross-section is circular (fig. 3). Spring swages (fig. 4) are frequently used instead of separate "top and bottom tools." Frequently swaging is practiced at once, without the preliminary detail of fullering. It is adopted when the amount of reduction is slight, and also when a steam hammer or other type of power hammer is available. This process of drawing down or fullering is, when practicable, adopted in preference to either upsetting or welding, because it is open to no objection, and involves no risk of damage to the material, while it improves the metal by consolidating its fibres. But its limitations in anvil work lie in the tediousness of the operation, when the part to be reduced is very much less in diameter, and very much longer, than the original piece of bar. Then there are other alternatives.

A long bar is required to have an enlargement at any portion of its length, not very much larger in diameter than the bar, nor of great length, upsetting is the method adopted. The part to be enlarged is heated, the parts adjacent remaining cold, and an end is hammered, or else lifted and dropped heavily on the anvil or on an iron plate, with the result that the heated portion becomes both shortened and enlarged (figs. 5 and 6). This process is only suitable for relatively short lengths, and has the disadvantage that the fibres of wrought iron are liable to open, and so cause weakening of the upset portion. But steel, which has no direction of fibre, can be upset without injury; this method is therefore commonly adopted in steam work, in powerful structures, when equal strength with drawing down. The alternative to upsetting is generally to weld a larger to a smaller bar or section, or to encircle the bar with a ring and weld the two (fig. 7). To do this a small hole is made, and a long quantity of power is absorbed, but the output is immensely greater than that of hand-made welds.

Bending is effected either by the hammer or by the simple exercise of leverage, the heated bar being pulled round a fulcrum. It is always, when practicable, preferable to cutting out a curved or angular shape with a hot sett or to welding. The continuity of the fibre in iron is preserved by bending, and the risk of an imperfect weld is avoided. Hence it is a simple and safe process which is constantly being performed at the anvil. An objection to sharp bends, or those having a small radius, is that the fibres become extended on the outer radius, the cross section being at the same time reduced below that of the bar itself. This is met by imparting a preliminary amount of upsetting to the part to be bent, sufficient to contract the amount of reduction due to extension of the fibres. A familiar example is seen in the corners of dip cranks.

The property possessed by pieces of iron or steel of uniting automatically while in a condition of semi-fusion is very valuable. When portions which differ greatly in dimensions have to be united, welding is the only method practicable at the anvil. It is also generally the best to adopt when union has to be made between pieces at right angles, or when a piece on which much work has to be done is required at the end of a long piece, as in the tension rods of cranes and other structures with eyes. The art of welding demands chiefly on having perfectly clean joint faces, free from scale, so that metal can unite to metal; union would be prevented by the presence of oxide or of dirt. Also it is essential to have a temperature sufficiently high, yet not such as to overheat the metal. A dazzling white, at which small particles of metal begin to drop off, is suitable for iron, but steel must not be made so hot. A very few hammer blows suffice to effect the actual union; if the joint be faulty, no amount of subsequent hammering will weld it. The forms of weld-joints include the scarf (figs. 8 and 9), the butt (fig. 10), the V (fig. 11) and the slot, one form of which is shown in fig. 12; the illustrations are of bars prepared for welding. These forms give the smith a suitable choice for different conditions. A convexity is imparted to the joint faces in order to favour the expulsion of slag and dirt during the closing of the joint; these undesirable matters become entangled between concave faces. The ends are upset or enlarged in order to leave enough metal to be dressed down flush, by swaging or by flattening. The proportional lengths of the joint faces shown are those which conform to good practice. The fluxes used for welding are numerous. Sand alone is generally dusted on wrought iron, but steel requires borax applied on the joint while in the fire, and also dusted on the joint at the anvil and on the face of the latter itself. Electric welding is largely taking the place of the hand process, but machines are required to maintain the parts in contact during the passage of the current. Butt joints are employed, and a large quantity of power is absorbed, but the output is immensely greater than that of hand-made welds.

When holes are not very large they are formed by punching; but large holes are preferably produced by bending a rod round and welding it, so forming an eye (fig. 13). Small holes are often punched simply as a preliminary stage in the formation of a larger hole by a process of drifting. A piece of work to be punched is supported either on the anvil or on a ring of metal termed a bolster, laid on the anvil, through which the burr, when severed, falls. But in making small holes through a thick mass, no burr is produced, the metal yielding sideways and forming an enlargement or boss. Examples occur in the wrought iron stanchions.
that carry light hand railing. In such cases the hole has to be punched from each face, meeting in the centre. Punching under power hammers is done similarly, but occupies less time.

The cutting-off or severance of material is done either on hot or cold metal. In the first case the chisels used, "hot sets," have keen cutting angles than those employed for the second, termed "cold sets." One set is held in a hole in the anvil face, the "anvil chisel," the other is handled and struck with a sledge.

The difference between iron and steel at the forge is that iron possesses a very marked fibre whereas steel does not. Many forgings therefore must be made differently according as they are in iron or in steel. In the first the fibre must never be allowed to run transversely to the axis of greatest tensile or bending stress, but must be in line therewith. For this reason many forgings, of which a common eye or loop (fig. 13) is a typical example, that would be stamped from a solid piece if made in steel, must be bent round from bar and welded if in wrought iron. Further, welding which is practically uniformly trustworthy in wrought iron, is distrusted in steel. The difference is due to the very fibrous character of iron, the welding of which gives much less anxiety to the smith than that of steel. Welds in iron are frequently made without any flux, those in steel never.

Though mention has only been made of iron and steel, other alloys are forged, as those of aluminium, delta metal, &c. But the essential operations are alike, the differences being in temperature at which the forging is done and nature of the fluxes used for welding. For hardening and tempering, an important section of smith's work, see annealing.

Die forging.—The smith operating by hand uses the above methods only. There is, however, a large and increasing volume of forgings produced in other ways, and comprehended under the general terms, "die forging" or "drop forging."

Little proof is needed to show that the various operations done at the anvil might be performed in a more expeditious way by the aid of power-operated appliances; for the elementary processes of reducing, and enlarging, bending, punching, &c., are extremely simple, and the most elaborate forged work involves only a repetition of these. The fact that the material used is entirely plastic when raised to a white heat is most favourable to the method of forging in matrix or dies. A white hot mass of metal can be placed in a matrix, and stamped into shape in a few blows under a hammer with as much ease as a medal can be stamped in steel dies under a coining press. But much detail is involved in the translation of the principle into practice. The parallel between coining dies and forging dies does not go far. The blank for the coin is prepared to such exact dimensions that no surplus material is left over by the striking of the coin, which is struck while cold. But the blank used in die forging is generally a shapeless piece, taken without any preliminary preparation, a mere lump, a piece of bar or rod, which may be square or round irrespective of whether the ultimate forging is to be square, or round, or flat or a combination of forms. At the verge of the welding heat to which it is raised, and under the intensity of the impact of hammer blows rained rapidly on the upper die, the metal yields like lead, and flows and fills the dies.

Herein lies a difference between striking a coin and moulding a forging. A large amount of metal is squeezed out beyond the concavity of the forging dies, and this would, if allowed to flow over between the joints, prevent the dies from being closed on the forging. There are two methods adopted for removing this "fin," or "flash" as it is termed, one being that of suppression, applicable to circular work, the other that of stripping, applied to almost all other cases.

The suppression of fin means that the circular bar is rotated in the dies (fig. 14) through a small arc, alternating between every few blows, with the result that the fin is obliterated immediately when formed, this being done at the same time that reduction of section is being effected over a portion or the whole of the bar.

Stripping means that when a considerable amount of fin has been formed, it is removed by laying the forging on a die pierced right through with an opening of the same shape and area as the forging, and then dealing the forging a blow with the hammer. The forging is thus knocked through the die, leaving the severed or stripped fin behind. The forging is then returned to the dies and again treated, and the stripping may be repeated twice, or even oftener, before the forging can be completed.

Figs. 15 and 16 illustrate the bottom dies of a set for forging in a particular form of eye, the top dies being of exactly the same shape. The first operation takes place in fig. 15, in which a bar of metal is reduced to a globular and cylindrical form, being constantly rotated meantime. The shank portion is then drawn down in the parallel recess to the left. The shape of the eye is completed in fig. 16, and the shank in the recess to the left of that. Fig. 17 shows how a lever is stamped between top and bottom dies. The double boss is formed by punching, the punches nearly meeting in the centre, and the centre for the hole to be drilled subsequently in the smaller boss is located by a conical projection in the top die.

It is evident that the methods of die forging, though only explained here in barest outline, constitute a principle of extensive application.

An intricate or ornamental forging, which might occupy a smith a quarter of a day in making at the anvil, can often be produced in dies within five minutes (fig. 18). On the other hand, there is the cost of the preparation of the dies, which is often heavy, so that the question of method is resolved into the relative one of the cost of dies, distributed over the number of identical forgings required. From this point of view it is clear that given a thousand forgings, ordered all alike, the cost of even expensive dies distributed over the whole becomes only an infinitesimal amount per forging.

There is, however, the very important fact that forgings which are produced in dies are uniform and generally of more exact dimensions than anvill-made articles. This is seen to be an advantage when forgings have to be turned or otherwise tooled in the engineer's machine shop, since it lessens the amount of work required there.

---

*Note: The diagrams in the text are not provided in this text-based format.*
Besides, for many purposes such forgings do not require tooling at all, or only superficially tooling, whereas anvil-made ones would, in consequence of their slight inaccuracies.

Yet again, die forging is a very elastic system, and herein lies much of its value. Though it reaches its highest development when thousands of similar pieces are wanted, it is also adaptable to a dozen, even to a hundred, or even to a dozen, similar forgings. In such cases economy is secured by using dies of a very simple kind; or, by using such dies as supplementary to anvil work for effecting next finish to more precise dimensions than can be ensured at the anvil. In the latter case the use is made of dies of bent iron moulded from patterns (fig. 19) instead of having their matrices laboriously cut in steel with drills, chisels and milling tools. In the second, preliminary drawing down is done under the steam hammer, and bending and welding at the anvil, or under the steam hammer, until the forgings are brought approximately to their final shape and dimensions.

Then they are re-heated and inserted in the dies, when a few blows under the steam or drop hammer suffice to impart a neat and accurate finish.

The limitations of die forging are chiefly those due to large dimensions. The system is most successful for the smallest forgings and dies which can be hand-worked by one man without the aid of any extra force. Even in large and massive forgings are not required in such large numbers as are those of small dimensions. But there are many large articles manufactured which do not strictly come under the term forgings, in which the aid of dies is of course utilized. These include work that is bent, drawn and shaped from steel plate, of which the fittings of railway wagons constitute by far the largest proportion. The dies used for some of these are massive, and a small specimen from one of the forms employed bends the steel plate between the dies to shape at once. Fairly massive forgings are also produced in these presses.

Die forging in its highest developments invades the craft of the skilled smith. In shops where it is adopted entirely, the only craftsmen required are those who have general charge of the shops. The men who attend to the machines are not smiths, but unskilled helpers.

FORK (Lat. furca), an implement formed of two or more prongs at the end of a shaft or handle, the most familiar type of which is the table-fork for use in eating. In agriculture and horticulture the fork is used for pitching hay, and other green crops, manure, &c.; commonly this has two prongs, "tines"; for digging, breaking up surface soil, preparing for hand weeding and for planting the three-pronged fork is used. The word is also applied to many objects which are characterized by branching ends, as the tuning-fork, with two branching metal prongs, which being struck with a hammer and gives a musical note, used to give a steady pitch; to the banks of a river, or the junction where a tributary runs into the main river; and in the human body, to that part where the legs branch off from the trunk.

The furca, two pieces of wood fastened together in the form of the letter Λ, was used by the Romans as an instrument of punishment. It was placed over the shoulders of the criminal, and his hands were fastened to it, condemned slaves were compelled to carry it about with them, and those sentenced to be flogged would be tied to it; crucifixions, were sometimes carried out on a similar shaped instrument. From the great defeat of the Romans by the Samnites at the battle of the Caudine Forks (Furculae Caulinae), a narrow gorge, where the vanquished were compelled to pass under the yoke (jugum), as a sign of submission, the expression "to pass through or under the forks" has been loosely used of such a disgraceful surrender. The "forks" in any allusion to this defeat should refer to the topographical name and not to the jugum, which consisted of two upright spears with a third placed transversely as a cross-bar.

FORKEL, JOHANN NIKOLAUS, German musician, was born on the 22nd of February 1740 at Mendeck in Coburg. He was the son of a cobbler, and as a practical musician, especially as a pianoforte player, achieved some eminence; but his claims to a more abiding name rest chiefly upon his literary skill and deep research as an historian of musical science and literature. He was an enthusiastic admirer of J. S. Bach, whose music he did much to popularize. His library, which was accumulated with care and discrimination at a time when rare books were cheap, forms a valuable portion of the royal library in Berlin and also of the library of the Königlicher Institut für Kirchenmusik. He was organist to the university church of Göttingen, obtained the degree of doctor of philosophy, and in 1778 became musical director of the university. He died at Göttingen on the 20th of March 1818. The following is a list of his principal works: Über die Theorie der Musik (Göttingen, 1777); Musikalisches kritisches Bibliothek (Gotha, 1778); Allgemeine Geschichte der Musik (Leipzig, 1788). The last is his most important work. He also wrote a Dictionary of Musical Literature, which is full of valuable material. To his musical compositions, which are numerous, little interest is to-day to be attached. But it is worth noting that he wrote variations on the English national anthem "God save the king" for the clavichord, and that Abt Vogler wrote a sharp criticism on them, which appeared at Frankfurt in 1793 together with a set of variations as he conceived they ought to be written.

FORLI (anc. Forum Livi), a town and episcopal see of Emilia, Italy, the capital of the province of Forlì, 40 m. S.E. of Bologna by rail, 105 ft. above sea-level. Pop. (1901) 15,461 (town); 43,321 (commune). Forlì is situated on the railway between Bologna and Rimini. It is connected by steam tramways with Ravenna and Modena, and by a road through the Apenines with Fontaniva. The church of S. Mercuriale stands in the central square, and contains, beside paintings and sculptures, a carved and inlaid choir stalls by Alessandro del Bigni. The façade has been considerably altered, but the campanile, erected in 1178-1180, still exists; it is 252 ft. in height, square and built of brickwork, and is one of the finest of Lombard campanili.

The pictures in this church are the work of Marco Palmezzano (1450-1537) and others; S. Biagio and the municipal picture gallery also contain works by him. The latter has other interesting pictures, including a fresco representing an apprentice with a pot and mortar (Pestapepe), the only authentic work in Forlì of Melozzo da Forlì (1438-1494), an eminent master whose style was formed under the influence of Piero della Francesca, and who was the master of Palmezzano; the frescoes in the Sforza chapel in SS. Biagio e Girolamo are from the former's designs, though executed by the latter. The church also contains the fine tomb (1466) of Barbara Manfredi. The cathedral (Santa Croce) has been almost entirely rebuilt since 1844. The Palazzo del Podesta, now a private house, is a brick building of the 15th century. The citadel (Rocca Ravadilana), constructed about 1350-1379, and later rebuilt, is now used as a prison. Flavio Biondo, the first historian of Italy, wrote in the 15th century on the topography of ancient Rome (1388-1463), was a native of Forlì.

Of the ancient Forum Livi, which lay on the Via Aemilia, hardly anything is known. In the 12th century we find Forlì in league with Ravenna, and in the 13th the imperial court of the province of Romagna resided there. In 1275 Forlì defeated Bologna with great loss. Martin IV. sent an army to besiege it in 1282, which was driven out after severe fighting in the streets; but the town soon afterwards surrendered. In the 14th and 15th centuries it was under the government of the Ordelaffi; and in 1500 was taken by Caesar Borgia, despite a determined resistance by Caterina Sforza, widow of Girolamo Riario. Forlì finally became a part of the papal state in 1504. (T. As.)

FORLIMPOPOLI (anc. Forum Popilii), a village of Emilia, Italy, in the province of Forlì, from which it is 5 m. S.E. by rail, 105 ft. above sea-level. Pop. (1901) 2299 (town); 5705 (commune). The ancient Forum Popilii, a station on the Via Aemilia, was destroyed by Grimuald in 672. Whether its site is occupied by the present town is not certain; the former probably be sought a mile or so farther to the S.E., where were found most of the inscriptions of which the peace of discovery is certain. Forlimpopoli was again destroyed by Cardinal Albornoz in 1360, and rebuilt by Sinibaldo Ordelaffi, who constructed the well-preserved medieval castle (1380), rectangular with four circular towers at the corners. (T. As.)
equivalent is ferns perduis, a military term (sometimes shortened to "forlorn"), used in the 16th and 17th centuries for a body of troops thrown out in front of the line of battle to engage the hostile line, somewhat after the fashion of skirmishers, though they were always solid closed bodies. These troops ran great risks, because they were often trapped between the two lines of battle as the latter closed upon one another, and fired upon or ridden down by their friends: but, as the general notion was to facilitate the attacks of their own main body by striking the first blow against or meeting the first shock of the fresh and unshaken enemy. In the following century (18th), when lines of masses were no longer employed, a thin line of skirmishers alone preceded the three deep line of battle, but the term "forlorn hope" continued to be used for picked bodies of men entrusted with dangerous tasks, and in particular for the storming party at the assault of a fortress. In this last sense "forlorn hope," is often used at the present time. The misunderstanding of the word "hope" has led to various applications of "forlorn hope" such as to an enterprise offering little chance of success, or, further still from the original meaning, to the faint or desperate hope of such success.

FORM (Lat. formā), in general, the external shape, appearance, configuration of an object, in contradistinction to the matter of which it is composed; thus a speech may contain excellent arguments—the matter may be good, while the style, grammar, arrangement—the form—is bad. The term, with its adjective "formal" and the derived nouns "formality" and "formalism," is hence employed by their friends: but, as the general notion was to facilitate the attacks of their own main body by striking the first blow against or meeting the first shock of the fresh and unshaken enemy. In the following century (18th), when lines of masses were no longer employed, a thin line of skirmishers alone preceded the three deep line of battle, but the term "forlorn hope" continued to be used for picked bodies of men entrusted with dangerous tasks, and in particular for the storming party at the assault of a fortress. In this last sense "forlorn hope," is often used at the present time. The misunderstanding of the word "hope" has led to various applications of "forlorn hope" such as to an enterprise offering little chance of success, or, further still from the original meaning, to the faint or desperate hope of such success.

FORMALIN, or FORMALDEHYDE, CH₃O or H-CHO, the first member of the series of saturated aliphatic aldehydes. It is most readily prepared by passing the vapour of methyl alcohol, mixed with air, over heated copper or platinum. In order to collect the formaldehyde, the vapour is condensed and absorbed, either in water or alcohol. It may also be obtained, although in small quantities, by the distillation of calcium formaldehyde. At ordinary temperatures formaldehyde is a gas possessing a pungent smell; it is a strong antisepic and disinfectant, a 40% solution of the aldehyde in water or methyl alcohol, sold as formalin, being employed as a deodorant, fungicide and preservative. It is not possible to obtain the aldehyde in a pure condition, since it readily polymerizes. It is a strong reducing agent; it combines with ammonia to form hexamethylene tetramine, (CH₃)₄N, and easily "condenses" in the presence of many bases to produce compounds which apparently belong to the sugars (p.). It renders glue or gelatin insoluble in water, and is used in the coal-tar color industry in the manufacture of para-rosaniline, pyronines and rosamines. Several polymers have been described. Para-formaldehyde, or trioxymethylene, obtained by concentrating solutions of formaldehyde in vacuo, is a white crystalline solid, which sublimes at about 100° C. and melts at a somewhat higher temperature, changing back into the original form. It is insoluble in cold water, alcohol and ether. A formaldehyde is supposed to separate as white flakes when the vapour is passed into chloroform (Saber, Pharm. Zeit., 1904, xlix. p. 600); F. Auerbach and M. Bachechi (Chem. news, 1905, p. 853); O. Fries (Chem. news, 1913, p. 201). Formaldehyde also appears to be a reduction product of carbon dioxide (see Annual Reports of the Chemical Society).

FORMAN, ANDREW (c. 1465-1521), Scottish ecclesiastic, was educated at the university of St Andrews and entered the service of King James IV. about 1480. He soon earned the favour of this king, who treated him with great generosity and who on several occasions sent him on important embassies to the English, the French and the papal courts. In 1501 he became bishop of Moray and in July 1513 Louis XII. of France secured his appointment as archbishop of Bourges, while pope Julius II. promised to make him a cardinal. In the following year he was named bishop of Amiens. In the interval he distanced long absence from his own land Forman was named bishop of Moray, and in July 1513 Louis XII. of France secured his appointment as archbishop of Bourges, while pope Julius II. promised to make him a cardinal. In the interval he distanced long absence from his own land Forman was named bishop of Amiens.
the see owing to the attempts of Henry VIII. to subdue Scotland to England and to the efforts of his rivals, Gavin Douglas, the poet, and John Hepburn, prior of St. Andrews, and their supporters. Eventually, however, he resigned some of his county benefices, the holding of which had made him unpopular, and through the good offices of the regent, John Stewart, duke of Albany, obtained the coveted archbishopric and the primacy of Scotland. Afterwards he was one of the vice-regents of the kingdom and he died on the 11th of March 1521. As archbishop he issued a series of constitutions which are printed in J. Robertson's Consilia Scotiae (1866). Mr. Andrew Lang (History of Scotland, vol. i.) describes Forman as "the Wobsey of Scotland, and a fomenter of the war which ended at Flodden." Some of the archbishop's later works forms vol. ii. of The Archbishops of St. Andrews, by J. Herkless and R. K. Hannay (1909).

FORMAN, SIMON (1552-1611), English physician and astrologer, was born in 1552 at Quidham, a small village near Wilton, Wiltshire. At the age of fourteen he became apprentice to a druggist at Salisbury, but at the end of four years he exchanged this profession for that of a schoolmaster. Shortly afterwards he entered Magdalen College, Oxford, where he studied chiefly medicine and astrology. After continuing the same studies in Holland he commenced practice as a physician in Philpot Lane, London, but as he possessed no diploma, he on this account underwent more than one term of imprisonment. Ultimately, however, he obtained a diploma from Cambridge university, and established himself as a physician and astrologer at Lambeth, where he was consulted, especially as a physician, by many persons of rank, among others by the notorious countess of Essex. He expired suddenly while crossing the Thames in a boat on the 17th of September 1611.

A list of Forman's works on astrology is given in Bliss's edition of the Athenae Oxonienses; many of his MS. works are contained in the Bodleian Library, the British Museum and the Plymouth Library. "Visits and Description of the Forman MSS. in the Public Library, Plymouth," was published in 1853.

FORMET, a French architectural term for the wall-rib carrying the web or filling-in of a vault (q.v.).

FORMEY, JOHANN HEINRICH SAMUEL (1711-1797), Franco-German author, was born of French parentage at Berlin on the 31st of May 1711. He was educated for the ministry, and at the age of twenty became pastor of the French church at Brandenburg. Having in 1736 accepted the invitation of a correspondent of Berlin, he was in the following year chosen professor of rhetoric in the French college of that city and in 1739 professor of philosophy. On the organization of the academy of Berlin in 1744 he was named a member, and in 1748 became its perpetual secretary. He died at Berlin on the 7th of March 1797. His principal works are La Belle Weissen (1741-1750, 6 vols.), a kind of novel written with the view of enforcing the precepts of the Wofian philosophy; Bibliothéque critique, ou mémoires pour servir à l'histoire littéraire ancienne et moderne (1746); Le Philosophie chrétien (1750); L'Emile chrétien (1764), intended as an answer to the Émile of Rousseau; and Souvenirs d'un citoyen (Berlin, 1789). He also published an immense number of contemporary memoirs in the transactions of the Berlin Academy.

FORMIA (anc. Formiae, called Mola di Gaeta until recent times), a town of Campania, Italy, in the province of Caserta, from which it is 48 m. W.N.W. by rail. Pop. (1901) 5514 (town); 8452 (commune). It is situated at the N.W. extremity of the Bay of Gaeta, and commands beautiful views. It lay on the ancient Via Appia, and was much frequented by the most wealthy Romans. There was considerable imperial property here and along the coast as far as Sperlonga, and there are numerous remains of ancient villas along the coast and on the slopes above it. The so-called villa of Cicero contains two well-preserved nymphs with Doric architecture. Its site is now occupied by the villa Capocce, once a summer residence of the kings of Naples. There are many other modern villas, and the sheltered bays (for the mountains rise abruptly behind the town) are covered with lemon, orange and pomegranate gardens. The now deserted monastery of the Monte Scari to the E. is also covered with remains of ancient villas; the hill is crowned by a large tomb, known as Torre Glanis. To the E. at Scarru is a large vixi with sulphate tars for the production of "Cyclone" oil. The ancient Formiae was, according to the legend, the home of the Laestrygonians, and later a Spartan colony (Ouipuas bâl rô elppn, Strabo v. 3, p. 233). It was a Volscian town, and, like Fundi, received the civitas sine suffragio from Rome in 338 (or 332 B.C.) because the passage through its territory had always been secure. This was strategically important for the Romans, as the military road definitely constructed by Appius Claudius in 312 B.C., still easily traceable by its remains, and in part followed by the high-road, traversed a narrow pass, which could easily be blocked, between Fundi and Formia, and from thence was the only way to the full citizenship, and, like it, was to a certain extent under the control of a praefectus sent from Rome, though it retained its three aediles. Mamurra was a native of Formia. Cicerone possessed a favourite villa here, and was murdered in its vicinity in 43 B.C., but neither the villa nor the tomb can be identified with any certainty. It was devastated by Sextus Pompeius, and became a colony, with duoviri as chief magistrates, under Hadrian. Portus Caietae (the modern Gaeta) was dependent upon it.

Dr. A. Ashby, "Desss incidents de Carlo Labruzzi," in Rilians de l'école francaise de Rome (1903), 410 seq. (T. As.)

FORMIC ACID. $\text{H}_2\text{CO}_3$ or $\text{H}_2\text{CO}_2\text{OH}$, the first member of the series of aliphatic monobasic acids of the general formula $\text{C}_n\text{H}_{2n}\text{O}_2$. It is distinguished from the other members of the series by certain characteristic properties; for example, it shows an aldehydic character in reducing silver salts to metallic silver, and it does not form an acid chloroide or an acid anhydride. Its nitrate (prussic acid) has an acid character, a property not possessed by the nitriles of the other members of the series; and, by the abstraction of the elements of water from the acid, the carboxylic monoxide is produced, a reaction which finds no parallel in the higher members of the series. Finally, formic acid is, as shown by the determination of its affinity constant, a much stronger acid than the other acids of the series. It occurs naturally in red ants (Lat. formica), in stinging nettles, in some mineral waters, in animal secretions and in muscle. It may be prepared artificially by the oxidation of methyl alcohol and of formaldehyde; by the rapid heating of oxalic acid (J. Gay-Lussac, Ann. chim. phys., 1831 [I] 46 p. 218), but best by heating formic acid with hydrogen bromide (C. Berthelot, Ann., 1856, p. 139). In the reaction a glycerol ester is formed as an intermediate product, and undergoes decomposition by the water which is also produced at the same time.

$\text{C}_2\text{H}_2\text{O}_2\text{H} + \text{H}_2\text{O} = \text{CH}_3\text{H}_2\text{O} + \text{CO} + \text{H}_2\text{O}$

Many other synthetical processes are in the course of the acid or its salts are known. Hydrolysis of hydrocyanic acid by means of hydrochloric acid yields formic acid. Chloroform boiled with alcoholic potash forms potassium formate (J. Dumas, Beresius Jahrberichte, vol. 15, p. 321), a somewhat similar decomposition being shown by chloral and aqueous potash (J. v. Liebig, Ann., 1832, p. 198). Formates are also produced by the action of moist carbon monoxide on soda lime at 190-290°C. (V. Mora and T. Thibierge, Ber., 1889, 13, p. 25; A. Guther, Ann., 1888, 202, p. 317), or by the action of moist carbon dioxide on potassium (H. H. Kellce and R. Schmitt, Ann., 1861, 119, p. 281). H. Moissan and L. Magnussen (Bull. soc. chim., 1888, 92, p. 602) distills the commercial acid, in vacuo, with concentrated sulphuric acid below 75°C. Formic acid is a colourless, sharp-smelling liquid, which crystallizes in needles or prisms of white, yellowish, or brown, with a gravity 1.22 (20°C). It is miscible in all proportions with water, alcohol and ether. When heated with zinc dust, the acid decomposes into carbon monoxide and hydrogen. The sodium and potassium salts, when heated to 400°C, give oxalates and carbonates of the
alkali metals, but the magnesium, calcium and barium salts yield carbonates only. The free acid, when heated with concentrated sulphuric acid, is decomposed into water and pure carbon monoxide, which is evolved and oxidized, it is first to oxalic acid and finally to carbon dioxide. The salts of the acid are known as forms, and are mostly soluble in water, those of silver and lead being the least soluble. Concentrated sulphuric acid converts them into sulphates, with simultaneous liberation of carbon monoxide. The calcium salt, when heated with the calcium salts of higher homologues, gives almost quantitatively the mercuric salts, when heated, yield the metal, with liberation of carbon dioxide and formation of free formic acid; and the ammonium salt, when distilled, gives some formamide. They crystallize well and are readily decomposed by distilling a mixture of the sodium or potassium salts and the corresponding alcohol with hydrochloric or sulphuric acids.

Formamide, HCONH₂, is obtained by heating ethyl formate with ammonia; by heating ammonium carbonate with urea, 140°C, HCONH₂+CO(NH₂)₂=2HCONH₂+(NH₂)₂CO, by heating ammonium formate in a sealed tube for some hours at 230°C, or by the action of sodium amalgam on a solution of potassium cyanate (H. Basarow, Ber., 1871, 4, p. 409). It is a liquid which boils in vacuo at 135°C, but at 192-193°C under ordinary atmospheric pressure, with partial decomposition into carbon monoxide and ammonia. It dissolves mercuric oxide, with the formation of mercuric formamide, (HCONH₂)₂Hg.

FORMOSA, a northern territory of the Argentine republic, bounded N. by Bolivia, N.E. and E. by Paraguay, S. by the Chaco Territory, and W. by Salta, with the Pilcomo and Bermejo forming its northern and southern boundaries. Estimated area, 41,402 sq. m. It is a vast plain, sloping gently to the S.E., covered with marshes and tropical forests. Very little is known of it except small areas on the Bermejo and Paraguay rivers, where attempts have been made to form settlements. The unexplored interior is still occupied by tribes of wild Indians. The climate is hot, the summer temperature rising to a maximum of 104°F. Timber-cutting is the principal occupation of the settlers, though stock-raising and agriculture engage some attention in the settlements on the Paraguay. The capital, Formosa (founded 1879), is a small settlement on the Paraguay with a population of about 1000 in 1900. The settled population of the territory was 4829 in 1895, which it was estimated had increased to 13,431 in 1905. The nomadic Indians are estimated at 8000.

FORMOSA (called Taivan by the Chinese, and following them by the Japanese, into whose possession it came after their war with China in 1895), an island in the western Pacific Ocean, between the Southern and the Eastern China Sea, separated from the Chinese mainland by the Formosa Strait, which has a width of about 90 m. in its narrowest part. The island is 225 m. long and from 60 to 80 m. broad, has a coast-line measuring 731 m., an area of 13,429 sq. m.—being thus nearly the same size as the island of Japan. It forms the Japanese empire—proper—and extends from 20° 56' to 25° 15' N. and from 120° to 122° E. It forms part of the long line of islands which are interposed as a protective barrier between the Asiatic coast and the outer Pacific, and is the cause of the immunity from typhoons enjoyed by the ports of China from Amoy to the Yellow Sea. Along the western coast is a low plain, not exceeding 20 m. in extreme width; on the east coast there is a rich plain called Giran, and there are also some fertile valleys in the neighbourhood of Karenko and Pinan, extending up the longitudinal valleys of the rivers Karenko and Pinan, between which and the east coast the Taito range intervenes; but the rest of the island is mountainous and covered with virgin forest. In the plains the soil is generally of sand or alluvial clay, covered in the valleys with a rich vegetable mould. The scenery of Formosa is frequently of majestic beauty, and to this it is indebted for its European name, happily bestowed by the early Spanish navigators.

On the addition of Formosa to her dominions, Fuji ceased to be Japan's highest mountain, and took the third place on the list of heights, 3705 ft. Mount Baron (2370 ft.), Mount Niitaka-yama (New High Mountain), stands first, and Mount Sylvia (17,480 ft.), to which they give the name of Setzu-zen (Snowy Mountain), comes second. Mount Morrison stands nearly under the Tropic of Cancer. It is not volcanic, but consists of argillaceous schist and quartzite. An ascent made by Dr Honda of the imperial university of Japan showed that, up to a height of 6000 ft., the mountain is clothed with primeval forests of palms, banyans, cork trees, camphor trees, tree ferns, interlacing creepers and dense thickets of rattan or stretches of grass higher than a man's stature. The next interval to 1000 ft. has gigantic cryptomerias and chamaecyparis; then follow pines; then, at a height of 9500 ft., a broad plateau, and then alternate stretches of grass and forest up to the top, which consists of several small peaks. There is no snow. Mount Morrison, being surrounded by high ranges, is not a conspicuous object. Mount Sylvia lies in 24° 50' N. lat. There are many other mountains of considerable elevation. In the north is Getsurubi-zan (4101 ft.); and on either side of Setzu-zen, with which they form a range running due east and west across the island, are Jusampunzan (4698 ft.) and Kalli-zen (7277 ft.). Twenty-two miles due south of Kalli-zen stands Hakumosha-zan (5282 ft.), and just 20 m. due south of Hakumosha-zan begins a chain of three peaks, Suishia-zen (6200 ft.), Hoo-zen (4928), and Niitaka-yama. These five mountains, Harizan-Hakumosha-zen, Suishia-zen, Hoo-zen and Niitaka-yama, stand almost exactly under 117° E. long., in the very centre of the island. But the backbone of the island lies east of them, extending S. from Setzu-zen through Gokan-zen, and Noko-zen and other peaks and bending S.W. to Niitaka-yama. Yet farther south, and still lying in line down the centre of the island, are Sankyyukan-zen (3752 ft.), Shurogi-zan (5729 ft.), Foren-zan (4935 ft.), and Kado-zen (9515 ft.), and, finally, in the south-east Arugan-zen (4985 ft.). These, it will be observed, are all Japanese names, and the heights have been determined by Japanese observers. In addition to these remarkable inland mountains, Formosa's eastern shores show magnificent cliff scenery, the bases of the hills on the seaside taking the form of almost perpendicular walls as high as from 1500 to 2500 ft. Volcanic outbreaks of steam and sulphur-springs are found. Owing to the precipitous character of the east coast few rivers of any size find their way to the sea in that direction. The west coast, on the contrary, has many streams, but the only two of any considerable length are the Kotansui, which rises on Shurogi-zen, and has its mouth at Toko after a course of some 60 m. and the Seirakei, which rises on Hakumosha-zen, and enters the sea at a point 57 m. farther north after a course of 90 m.

The climate is damp, hot and malarious. In the north, the driest and best months are October, November and December; in the south, December, January, February and March. The sea immediately south of Formosa is the birthplace of innumerable typhoons, but the high mountains of the island protect it from the same wind. The rain in Formosa falls in torrents, and is of the warm season of the wind.

Flora and Fauna.—The vegetation of the island is characterized by tropical luxuriance,—the mountainous regions being clad with dense forest, in which various species of palms, the camphor-tree (Laurus Camphora), and the aloe are conspicuous. Consul R. Swinhoe obtained no fewer than 65 different kinds of timber from a large yard in Taiwan; and his specimens are now to be seen in the museum at Kew. The tree which supplies the materials for the pith paper of the Chinese is not uncommon, and the cassia tree is found in the mountains. Travellers are especially struck with the beauty of some of the wild flowers, more especially with the lilies and convolvuluses; and European greenhouses have been enriched by several Formosan orchids and other ornamental plants. The pine-apple grows in abundance. In the lowlands of the western portion, the Chinese have introduced a large number of cultivated plants and fruit trees. Rice is grown in such quantities as to procure for Formosa, in former days, the title of the "granary of China"; and the sweet potato, taro, millet, barley, wheat and maize are also cultivated. Camphor, sugar, tea, indigo, ground peanuts, jute, hemp, oil and rattan are all articles of export.

The Formosan fauna has been but partially ascertained; but at least three kinds of deer, wild boars, bears, goats, monkeys (probably Macacus speciosus), squirrels, and flying squirrels
FORMOSA

are fairly common, and panthers and wild cats are not uncommon. A poisonous but beautiful green snake is often mentioned by travellers. Pheasants, ducks, geese and snipe are abundant, and Dr C. Collingwood in his Naturalist's Rambles in the China Seas mentions Ardea prasinaceus and other species of herons; seven species of fly-catchers, kingfishers, shrikes, shrikes, and larks, the black drongo, the Ceyx sinesis and the Prinia solitaria. Dogs are kept by the savages for hunting. The horse is hardly known, and his place is taken by the ox, which is regularly bridled and saddled and ridden with all dignity. The rivers and neighbouring seas seem to be well stocked with fish, and especial mention must be made of the turtles, flying-fish, and brilliant coral-fish which swarm in the waters warmed by the Kuroshio current, the gulf-stream of the Pacific. Shell-fish form an important article of diet to both the Chinese and the aborigines along the coast—a species of Cyrena, a species of Tagma, Ceyx sinesis and Maloia teres being most abundant.

Population.—The population of Formosa, according to a census in 1901, is estimated at 5,022,657, made up as follows: aborigines 104,334, Chinese 2,860,574 and Japanese 51,770. The inhabitants of Formosa may be divided into four classes: the Japanese, who are comparatively few, as there has not been much tendency to immigration; the Chinese, many of whom immigrated from the neighbourhood of Amoy and speak the dialect of that district, while others were Hakka from the vicinity of Swatow; the subjugated aborigines, who were essentially intermingled with the Chinese; and the uncivilized aborigines of the eastern region who refuse to recognize authority and carry on raids as opportunity occurs. The semi-civilized aborigines, who adopted the Chinese language, dress and customs, were called Pe-pa-hwan (Anglice Peho-hoans), while their wild brethren bear the name of Chin-hwan or "green savages," otherwise Sheng-fan or "wild savages." They appear to belong to the Malay stock, and their language bears out the supposition. They are broken up into almost countless tribes and clans, many of whom are still in the state of a savage nation, and their language consequently presents a variety of dialects, of which no classification has yet been effected: in the district of Posia alone a member of the Presbyterian mission distinguished eight different mutually unintelligible dialects. The people themselves are described as "middle height, broad-shouldered and muscular, with remarkably large hands and feet, the eyes large, the forehead round, and not narrow or receding in many instances, the nose broad, the mouth large and disfigured with betel." The custom of tattooing is universal. In the north of the island at least, the dead are buried in a sitting position, under the bed on which they have expired. Petty wars are extremely common, not only along the Chinese frontiers, but between the neighbouring clans, and the heads of the slain are carefully preserved as trophies. In some districts the young men and boys sleep in the skull-chambers, in order that they may be inspired with courage. Many of the tribes that had least intercourse with the Chinese show a considerable amount of skill in the arts of civilization. The use of Manchester prints and other European goods is fairly general; and the women, who make a fine native cloth from hemp, introduced coloured threads from the foreign stuffs, so as to produce ornamental devices. The office of chieftain is sometimes held by women.

The chief town is Taipe (called by the Japanese T'ai-ho), which is on the Tamsui-yei river, and has a population of about 118,000, including 58,500 Japanese. Taipe may be said to have two ports; one, Tamsui, at the mouth of the river Tamsui-yei, 10 m. distant on the north-west coast, the other Kelung (called by the Japanese Ki-run), on the north-east shore, with which it is connected by rail, a run of some 18 m. The foreign settlement at Taipe lies outside the walls of the city, and is called Twatutia (Taito) by the Japanese. Kelung (the ancient Peking) is an excellent harbour, and the scenery is very beautiful. There are coal-mines in the neighbourhood. Tamsui (called Tansui by the Japanese) is usually termed Hobe by foreigners. It is the site of the first foreign settlement, has a population of about 7,000, but cannot be made a good harbour without considerable expenditure. On the west coast there is no place of any importance until reaching Anping (23° N. lat.), a port where a few foreign merchants reside for the sake of the sugar trade. It is an unhealthy place, surrounded by mud flats, and a hotbed of malaria. It has a population of 400 Chinese and 60 Japanese. At a distance of some 21 m. inland is the former capital of Formosa, the walled city of Taian, which has a population of 100,000 Chinese, 2,300 Japanese, and a few British merchants and missionaries. Connected with Anping by rail (26 m.) and lying south of it is Takaau, a treaty port. It has a population of 6,500, and is prettily situated on two sides of a large lagoon. Six miles inland from Takaau is a prosperous Chinese town called Fenghsang (Japanese, Hozan). The anchorages on the east coast are Soo, Karenko and Finan, which do not call for special notice. Forty-seven m. east of the extreme south coast there is a little island called Botel Tobago (Japanese, Koto-sho), which rises to a height of 1,014 ft. and is inhabited by a tribe whose customs differ essentially from those of the natives on the main island.

Administration and Commerce.—The island is treated as an outlying territory; it has not been brought within the full purview of the Japanese constitution. Its affairs are administered by a governor-general, who is also commander-in-chief of the forces, by a bureau of civil government, and by three prefectural governors, below whom are the heads of twenty territorial districts. The Japanese called chin, its finances are not included in the general budget of the Japanese empire; it is garrisoned by a mixed brigade taken from the home divisions; and its currency is on a silver basis. One of the first abuses with which the Japanese had to deal was the excessive use of opium by the Chinese settlers. To interdict the importation of the drug altogether, as is done in Japan, was the step advocated by Japanese opinion. But, influenced by medical views and by the almost insuperable difficulty of enforcing any drastic import veto in the face of Formosa's large communications by junk with China, the Japanese have extended the law regulating opium, imposing preparation and sale of the drug, and limiting its use to persons in receipt of medical sanction. Under the administration of the Japanese the island has been largely developed. Among other industries gold-mining is advancing rapidly. In 1902 48,400 oz. of gold representing a value of £168,626 were obtained from the mines and alluvial washings. Coal is also found in large quantities near Kelung and sulphur springs exist in the north of the island.

An extensive scheme of railway construction has been planned, the four main lines projected being (1) from Takaau to Tainan; (2) from Tainan to Kagi; (3) from Kagi to Shoka; and (4) from Shoka to Kelung; these four forming, in effect, a main trunk road running from the south-west to the north-east, its course being along the foot of the mountains that border the western coast-plains. The Takaau-Tainan section (26 m.) was opened to traffic on the 3rd of November 1905, and by 1907 the whole line of 259 m. was practically complete. Harbour improvements also are projected, but in Formosa, as in Japan proper, paucity of capital constitutes a fatal obstacle to rapid development.

There are thirteen ports of export and import, but 75% of the total business is done at Tamsui. Tea and camphor are the staple exports. The greater part of the former goes to Amoy for re-shipment to the west, but it is believed that if harbour improvements were effected at Tamsui so as to render it accessible for ocean-going steamers, shipments would be made thence direct to New York. The camphor trade being a government monopoly, the quantity exported is under strict control.

History.—The island of Formosa must have been known from a very early date to the Chinese who were established in the islands called T'ang-fan or eastern barbarians; and under the Ming dynasty the island begins to appear as Kilung. In the beginning of the 16th century it began to be known to the Portuguese and Spanish navigators, and the latter at least made some attempts at establishing settlements or missions. The Dutch were the first, however, to take footing in the island;
in 1624 they built a fort, Zelandia, on the east coast, where subsequently rose the town of Taiwan, and the settlement was maintained for thirty-seven years. On the expulsion of the Ming dynasty in China, a number of their defeated adherents came over to Formosa, and under a leader called in European accounts Coxinga, succeeded in expelling the Dutch and taking possession of a good part of the island. In 1662 the Chinese of Formosa recognized the emperor of K'ang-hsi, and the island then began to form part of the Chinese empire. From the close of the 17th century a long era of conflict ensued between the Chinese and the aborigines. A more debased population than the peoples thus struggling for supremacy could scarcely be conceived. The aborigines, Sheng-fan, or "wild savages," desired the appellation in some respects, for they lived by the chase and had little knowledge even of husbandry; while the Chinese themselves, uneducated labourers, acknowledged no right except that of might. The former were not implacably cruel or vindictive. They merely clung to their homesteads, and harboured a natural resentment against the robbers who had dispossessed them. Their disposition was to leave the Chinese in un molested possession of the plain. But some of the most valuable products of the island, as camphor and rattan, are to be found in the upland forests, and the Chinese, whenever they ventured too far in search of these products, fell into ambushes of hill-men who neither gave nor sought quarter, and who regarded a Chinese skull as a specially attractive article of household furniture. A violent rebellion is mentioned in 1788, probably occasioned by the loss, it is said, of 500,000 men by disease and sword, and the destruction of crops and silver. Reconciliation never took place on any large scale, though it is true that, in the course of time, some fitful displays of administrative ability on the part of the Chinese, and the opening of partial means of communication, led to the pacification of a section of the Sheng-fan, who thenceforth became known as Pe-pa-hwan (Pepehoun).

In the early part of the 19th century the island was chiefly known to Europeans on account of the wrecks which took place on its coasts, and the dangers that the crews had to run from the cannibal propensities of the aborigines, and the almost equally cruel tendencies of the Chinese. Among the most notable was the loss in 1842 of the British brig "Ann," with fifty-seven persons on board, of whom forty-three were executed at Taichu. By the treaty of Tientsin (1860) Taichu was opened to European commerce, but the place was found quite unsuitable for a port of trade, and the harbour of Tam-sui was selected instead. From 1859 both Protestant and Presbyterian missions were established in the island. An attack made on those at Feng-shan (Hozan) in 1868 led to the occupation of Port Zelandia and the murder of two Europeans; but this action was later disapproved by the home government, and the indemnity demanded from the Chinese restored. In 1874 the island was invaded by the Japanese for the purpose of obtaining satisfaction for the murder of a shipwrecked crew who had been put to death by one of the semi-savage tribes on the southern coast, the Chinese government being either unable or unwilling to punish the culprits. A war was averted through the good offices of the British minister, Sir T. F. Wade, and the Japanese retired on payment of an indemnity of 500,000 taels. The political state of the island during these years was very bad; in a report of 1872 there is recorded a proverb among the official classes, "every three years an outbreak, every five a rebellion;" but subsequent to 1877 some improvement was manifested, and public works were pushed forward by the Chinese authorities. In 1884, in the course of belligerent proceedings arising out of the Tongking dispute, the forts at Kelung on the north were bombarded by the French fleet, and the place was captured and held for some months by French troops. An attack on the neighbouring town of Tamsui failed, but a semi-blockade of the island was maintained by the French fleet during the winter and spring of 1884-1885. The troops were withdrawn on the conclusion of peace in June 1885.

In 1895 the island was ceded to Japan by the treaty of Shimonoseki at the close of the Japanese war. The resident Chinese officials, however, refused to recognize thecession, declared a republic, and prepared to offer resistance. It is even said they offered to transfer the sovereignty to Great Britain if that power would accept it. A formal transfer to Japan was made in June of the same year in pursuance of the treaty, the ceremony taking place on board ship outside Keelung, as the Chinese officials did not take the trouble to land. The Japanese were thus left to take possession as best they could, and some four months elapsed before they effected a landing on the south of the island. Takau was bombarded and captured on the 19th of October, and the resistance collapsed. Liu Yung-fu, the notorious Black Flag general, and the back-bone of the resistance, sought refuge in flight. The general state of the island when the Japanese assumed possession was that the plain of Giran on the eastern coast and the hill-districts were inhabited by semi-barbarous folk, the western plains by Chinese of a degraded type, and that between the two there existed a traditional and continuous feud, leading to mutual displays of merciless and murderous violence. By many of these Chinese settlers the Japanese conquerors, when they came to occupy the island, were regarded in precisely the same light as the Chinese themselves had been regarded from time immemorial by the aborigines. Insurrections occurred frequently, the insurgents receiving secret aid from sympathizers in China, and the difficulties of the Japanese being increased not only by their ignorance of the country, which abounds in fastnesses where bandsites can find almost inaccessible refuge, but also by the unwillingness of experienced officials to abandon the home posts for the purpose of taking service in the new territory.

FORMOSUS, pope from 891 to 896, the successor of Stephen V. (or VI.). He first appears in history when, as bishop of Porto, he was sent on an embassy to the Bulgarians. Having afterwards sided with a faction against John VIII., he was excommunicated, and compelled to take an oath never to return to Rome or again to assume his priestly functions. From this oath he was, however, exonerated by Marinus, the successor of John VIII., and restored to his dignities; and on the death of Stephen V. in 891 he was chosen pope. At that time the Holy See was engaged in a struggle against the oppression of the princes of Spoleto, and a powerful party in Rome was eager to obtain the intervention of Arnulf, king of Germany, against these dangerous neighbours. Formosus himself shared this view; but he was forced to yield to circumstances and to consecrate as emperor Lambert, the young son of Guy of Spoleto. Guy had already been consecrated by Stephen V., and died in 894. In the following year Arnulf succeeded in seizing Rome, and Formosus crowned him emperor. As the pope was alleged to be the cause of this revolution, he was seized with paralysis, and was forced to return to Germany. Overwhelmed with chagrin, Formosus died on the 4th of April 896. The discord in which he had been involved continued after his death. The validity of his acts was contested on the pretext that, having been originally bishop of Porto, he could not be a legitimate pope. The fundamental factor in these dissensions was the rivalry between the princes of Spoleto and the Carolingian house, represented by the king of Germany. The body of Formosus was disinterred in 897 by Stephen VI., and treated with contumely as that of a usurper of the papal throne; but Theodore II. restored it to Christian burial, and at a council presided over by John IX. the pontificate of Formosus was declared valid and all his acts confirmed. (L. D.*)
FORMULA—FORREST, SIR J.

FORMULA (Lat. diminutive of forma, shape, pattern, &c., especially used of rules of judicial procedure), in general, a stereotyped form of words to be used on stated occasions, for specific purposes, ceremonies, &c. In the sciences, the word usually denotes a symbolic statement of certain facts; for example, a chemical formula exhibits the composition of a substance (see Chemistry); a botanical formula gives the differentiation of a plant; a ditionary formula indicates the arrangement and number of the teeth of an animal.

FORNER, JUAN BAUTISTA PABLO (1756-1799), Spanish satirist and scholar, was born at Mérida (Badajoz) on the 23rd of February 1756, studied at the university of Salamanca, and was called to the bar at Madrid in 1783. During the next few years—under the pseudonyms of 'Don Tomás de Cárdenas,' "Pablo Segarra," "Don Antonio Varas," "Bartolo," "Pablo Ignacio," "El Bachiller Regañadientes," and "Silvio Libero"—Foner was engaged in a series of polemics with García de la Huerta, Iriarte and other writers; the violence of his attacks was so extreme that he was finally forbidden to publish any controversial pamphlets, and was transferred to a legal post at Seville. In 1796 he became crown prosecutor at Madrid, where he died on the 17th of March 1799. Foner's brutality is almost unexampled, and his satirical writings give a false impression of his powers. His Oración apologetica por la España y su mérito literario (1787) is an excellent example of learned advocacy, far superior to similar efforts made by Denina and Antonio Cavanilles; and his posthumous Exequias de la lengua castellana (printed in the Biblioteca de autores españoles, vol. ixii.) testifies to his scholarship and taste.

FORRES (Gaelic, far uis, "near water"), a royal and police burgh of Elginshire, Scotland. Pop. (1891) 3971; (1901) 4317. It is situated on the Findhorn, which sweeps past the town and is crossed by a suspension bridge about a mile to the W., 11 m. W. of Elgin by the Highland railway, and 6 m. by road from Elgin. The northern half of the town is situated near the towns in the north of Scotland. King Donald (892-900), son of Constantine, died in Forres, not without suspicion of poisoning, and in it King Duff (691-697) was murdered. Macbeth is said to have slain Duncan in the first structure that gave its name to Castlehill, which was probably the building demolished in 1929 by the adherents of Wallace. The next castle was a royal residence from 1189 to 1371 and was occupied occasionally by William the Lion, Alexander II. and David II. It was burned down by the Wolf of Badenoch in 1390. The ruins on the hill, however, are those of a later edifice due north of the present town. At the town, to the north, in the early 16th century, granite obelisk, 65 ft. high, raised to the memory of Surgeon James Thomson, a native of Cormarty, who at the cost of his life tended the Russian wounded on the field of the Alma. The public buildings include the town hall, a fine and commodious house on the site of the old tolbooth; the Falconer museum, containing among other exhibits several valuable fossils, and named after Dr. Hugh Falconer (1805-1869), the distinguished palaeontologist and botanist, a native of the town; the mechanics' institute; the agricultural and market hall; Leuchnool hospital and Anderson's Institution for poor boys. The cross, in Decorated Gothic, stands beside the town hall. Adjoining the town on the south-east is the beautifully-wooded Culney Hill, a favourite public resort, carrying on its summit the tower, 70 ft. high, which was erected in 1806 to the memory of Nelson, and on its southern slopes a well-known hydroopathic. An excellent golf-course extends from Kinloss to Findhorn. The industries comprise the manufacture of chemicals and artificial manures, granite polishing, flour and sawmills, boot- and shoe-making, carriage-building and woollen manufactures. There is also considerable trade in cattle.

Sueno's Stone, about 23 ft. high, probably the finest sculptured monument in Scotland, stands in a field to the east of the town. Its origin and character have given rise to endless surmises. It is carved with figures of soldiers, priests, slaughtered men and captives on one side, and on the other with a cross and Runic ornamentation. One theory is that it is a relic of the early Christian church, symbolizing the battle of life and the triumph of good over evil. According to an older tradition it was named after Sueno, son of Harold, king of Denmark, who won a victory on the spot in 1008. A third conjecture is that it commemorates the expulsion of the Danes from Moray in 1014. Skene's view is that it chronicles the struggle in 900 between Sigurd, earl of Orkney, and Macluig, Maormor of Moray. Another story is that it is the Witches' Stone, because it marks the place near Forres where Macbeth is said to have encountered the weird sisters.

Forres is one of the Inverness district group of parliamentary burghs, the other being Nairn, Portnose and Inverness. The town is amongst the healthiest in Scotland and has the lowest rainfall in the county.

West of Forres to the S.W., lie the beautiful woods of Allytre, the seat of the Gordon-Cumings. Three miles farther south is Relugas House, the favourite residence of Sir Thomas Dick Lauder, romantically situated on a height near the confluence of the Divie and the Findhorn. Not far away stand the ruins of the old castle of Dunphail. On the left bank of the Findhorn, 3/4 m. W. of Forres, is situated Brodie Castle, partly ancient and partly modern. The Brodies—the old name of their estate was Brothie, from the Irish broth, a ditch, in allusion to the trench that ran from the village of Dyke to the north of the symposium and on the west of the town. Near the ruins was erected by Archibald Douglas, earl of Moray, in 1450. Queen Mary held a council in it in 1562. Earl Randolph's chair, not unlike the coronation chair, has been preserved. Kinloss Abbey, now in ruins, stands some 2½ m. to the N.E. of Forres. It was founded in 1150 by David I., and remained in the hands of the Cistercians till its suppression at the Reformation. Robert Reid, who ruled from 1326 to 1350, was its greatest abbot. His hobby was gardening, and it is believed that many of the 123 varieties of pears and 146 varieties of apples for which the district is famous were due to his skill and enterprise. Edward I. stayed in the abbey for a short time in 1393 and Queen Mary spent two nights in it in 1562.

FORREST, EDWIN (1806-1872), American actor, was born at Philadelphia, Pennsylvania, on the 9th of March 1806, of Scottish and German descent. He made his first stage appearance on the 27th of November 1820, at the Walnut Street theatre, in Home's Douglas. In 1836 he had a great success in New York as Othello. He played at Drury Lane in the Gladiator in 1836, but his Macbeth in 1845 was hissed by the English audience, and his afront to Macready in Edinburgh shortly afterwards—when he stood up in a private box and hissed him,—was fatal to his popularity in Great Britain. His jealousy of Macready resulted in the Astor Place riot in 1849. In 1857 he married Catherine, daughter of John Sinclair, an English singer, and his divorce suit in 1852 was a cause célèbre which hurt his reputation and soured his temper. His last appearance was as Richelieu in Boston in 1871. He died on the 12th of December 1872. He had amassed a large fortune, much of which he left by will to found a home for aged actors.

See Lawrence Barrett's Edwin Forrest (Boston, 1881).

FORREST, SIR JOHN (1847— ), West Australian statesman and explorer, son of William Forrest, of Bunbury, West Australia, was born near Bunbury, on the 22nd of August 1847, and educated at Perth, W.A. In 1865 he became connected with the Government Survey Department at Perth, and in 1869 led an exploring expedition into the interior in search of D. Leichhardt, penetrating through bush and salt-marshes as far inland as
FORSSELL

His When grant West historical superior in their all cavalry education Hamersley. in 1863-1864 Ashburton Champion the 1876 apart in according in the brilliant War he was five and troops of the arm. after December 1849), Forrest, popular in Mississippi, and remained a remarkable man. Wilson, one of the ablest of the Union cavalry generals, rapidly forced back the few Confederates, now under Forrest's command, and stormed Selma, Alabama, on the 2nd of April. The surrender of General Forrest and his whole command, under the agreement between General Richard Taylor and General E. S. Canby, followed on the 9th of May. After the war he lived in Memphis. He sold his cotton plantation in 1867, and for some years was president of the Selma, Marion and Memphis Railroad. He died at Memphis, Tennessee, on the 20th of October 1877.

The military career of General Forrest, apart from questions of his technical skill, horsemastership and detail special to his arm of the service, was admittedly that of a great leader. He never commanded a large force of all arms. He was uneducated, and had neither experience of nor training for the strategical handling of great armies. Yet his personality and his natural soldierly gifts were such that General Sherman considered him "the most remarkable man the Civil War produced on either side." Joseph Johnston, the Confederate general whose greatness lay above all in calm and critical judgment, said that Forrest, had he had the advantage of a thorough military training, "would have been the great central figure of the war."

See the biographies by J. A. Weyth (1899) and J. H. Mathes (1902).

FORSKAL, PETER (1730-1765), Swedish traveller and naturalist, was born in Kalmar in 1736. He studied at Göteborg, where he published a dissertation entitled Dubia de principiis philosophiae recentioris (1756). Thence he returned to his native country, which, however, he had to leave after the publication of a pamphlet entitled Pensées sur la liberté civile (1759). By Linnaeus he was recommended to Frederick V. of Denmark, who appointed him to accompany Carsten Niebuhr in an expedition to Arabia and Egypt in 1761. He died at the plague at Jerim in Arabia on the 11th of July 1763.

His friend and companion, Niebuhr, was entrusted with the care of visiting his Majesty, and published in 1775 Description animalium, avium, amphibiorum, piscium, insetorum, vermis, quae in itin. Orienti, observavit Petrus Forskål. In the same year he also issued an account of the Flora Felixi and of lower Egypt, under the title of Flora Aegyptiaco-Arabicae.

FORSELL, HANS LUDVIG (1843-1901), Swedish historian and political writer, the son of Adolf Forsell, a distinguished mathematician, was born at Gelle, where his father was professor, on 14th January 1843. At the age of sixteen he became a student in Upsala University, where he distinguished himself, and where, in 1866, having taken the degree of doctor, he was appointed reader in history. At the age of thirty, however, Forsell, who had already written several works, was called to Stockholm, where he filled one important post after another in the Swedish civil service. In 1875 he was appointed head of the treasury, and in 1880 was transferred to the department of inland revenue, of which he continued to be president until the time of his death. In addition to the responsibilities which these offices devolved upon him, Forsell was constantly called to serve on royal commissions, and his political influence was immense. In spite of all these public employments he carried on, with the greatest diligence, Forsell also found leisure for an abundant literary activity. Of his historical writings the most important were: The Ad- ministrative and Economic History of Sweden after Gustavus I. (1860-1875) and Sweden in 1571 (1872). He was also for several years, in company with the poet Wirsén, editor of the Swedish Literary Review. He published two volumes of Studies and
FORST—FORSTER, J. G. A.

Criticism (1875, 1888). In the year 1881, at the death of the historian Anders Fryxell, Forssell was elected to the vacant seat on the Swedish Academy. The energy of Forssell was so great, and he understood so little the economy of strength, that his unexpected death, which occurred with great suddenness on the 2nd of August 1901, while he was staying at San Bernardino in Switzerland, was wholly unexpected. There was little of the typical Swedish urbanity in Forssell's exterior manner, which was somewhat dry and abrupt. Like many able men who have from early life administered responsible public posts, there appeared a certain want of sympathy in his demands on others. His views were distinct, and held with great firmness; for example, he was a free-trader, and his consistent opposition to what he called "the new system" had a considerable effect on Swedish policy. He was not exactly an attractive man, but he was a capable, upright and efficient public servant. In 1896 he married Miss Zulamith Eneroth, a daughter of the well-known pomologist of Upsala; she survived him, with two sons and two daughters. (E. G.)

FORST (originally FORSTA or FORSTE), a town of Germany, in the Prussian province of Brauband, on the Neisse, 44 m. S.E. of Frankfort-on-Oder. Pop. (1905) 33,757. It has two Evangelical, a Roman Catholic and an Old Lutheran church; there are two schools and two hospitals in the town. The chief industry of Forst is the manufacture of cloth, but spinning, dyeing and the making of artificial flowers are also carried on. Founded in the 13th century, Forst passed in 1667 to the duke of Saxe-Merseburg, becoming part of electoral Saxony in 1740. It was ceded to Prussia in 1815.

FORSTER, FRANCOIS (1790-1872), French engraver, was born at Lecle in Neuffchatel, on the 22nd of August 1790. In 1805 he was apprenticed to an engraver in Paris, and he also studied painting and engraving simultaneously in the École des Beaux-Arts. His preference was ultimately fixed on the latter art, and on his obtaining in 1814 the first "grand prix de gravure," the king of Prussia, who was then with the allies in Paris, bestowed on him a gold medal, and a pension of 1500 francs for two years. With the aid of this sum he pursued his studies in Rome, where his attention was devoted chiefly to the works of Raphael. In 1844 he succeeded Tardieu in the Academy. He died at Paris on the 27th of June 1872. Forster occupied the first position among the French engravers of his time, and was equally successful in historical pieces and in portraits. Among his best known works he may be mentioned—The Three Graces, and La Vierge de la légende, after Raphael; La Vierge au bas-relief, after Leonardo da Vinci; Francis I. and Charles V., after Gros; St Cécilia, after Paul Delaroche; Albert Dürer and Henry IV., after Porbus; Wellington, after Gérard; and Queen Victoria, after Winterhalter.

FORSTER, FRIEDRICH CHRISTOPH (1791-1868), German historian and poet, was the second son of Karl Christoph Förster (1751-1811), and consequently a brother of the painter, Ernest Joachim Förster (1800-1839). Born at Münchensgosterstadt on the Spree on the 24th of September 1791, he received his early education at Altenburg, and after a course of theology at Jena, devoted some time to archaeology and the history of art. At the outbreak of the War of Liberation in 1813, he joined the army, quickly attaining the rank of captain; and by his war-songs added to the national enthusiasm. On the conclusion of the war he was appointed professor at the school of engineering and artillery in Berlin, but on account of some democratic writings he was dismissed from this office in 1817. He then became connected with various journals until about 1820, when he received an appointment at the royal museum in Berlin, with the title of court councillor (Hofrat). He was the founder and secretary of the Wissenschaftlicher Kunstverein in Berlin, and died in Berlin on the 8th of November 1868. Förster's principal works are: Beiträge zur neueren Kriegsgeschichte (Berlin, 1816); Grundzüge der Geschichte des preussischen Staates (Berlin, 1818); Der Feldmarschall Bücher und seine Umgebungen (Leipzig, 1826); Friedrich der Grosse, Jugendjahre, Bildung und Geist (Berlin, 1832); Albrecht von Wallenstein (Potsdam, 1834); Friedrich Wilhelm I., König von Preussen (Potsdam, 1834-1835); Die Heil und Kabinette Europas im 18. Jahrhundert (Potsdam, 1836-1830); Leben und Taten Friedriicks des Grossen (Meissen, 1840-1841); Wallensteinisches Prosai (Leipzig, 1844); and Preussen Held in Krieg und Frieden, neure und neueste preussische Geschichten, 7 volumes (Berlin, 1849-1860). The three concluding volumes of this work contain the history of the war of liberation of 1813-14-15. He brought out an edition of Hegel's works, adapted several of Shakespeare's plays for the theatre, wrote a number of poems and an historical drama, Gustav Adolf (Berlin, 1832).

Many of his lesser writings were collected and published as Kriegsgeschichten, Erzählungen und Legenden (Berlin, 1828). The twenty-four years of his professorship of French language and the elements of a scientific education. After a few years the father quarrelled with the Russian government, and went to England, where he obtained a professorship of natural history and the modern languages at the famous non-conformist academy at Warrington. His violent temper soon compelled him to resign this appointment, and for two years he and his son earned a precarious livelihood by translations in London—a practical education, however, exceedingly useful to the younger Förster, who became a thorough master of English, and acquired many of the ideas which chiefly influenced his subsequent life. At length the turning point in his career came in the shape of an invitation for him and his father to accompany Captain Cook in his third voyage round the world. Such an expedition was admirably calculated to call forth Förster's peculiar powers. His account of Cook's voyage (A Voyage round the World, London, 1777; in German, Berlin, 1778-1780) is almost the first example of the glowing yet faithful description of natural phenomena which has since made a knowledge of them the common property of the educated world. The publication of this work was, by some time by differences with the Admiralty, during which Förster proceeded to the continent to obtain an appointment for his father as professor at Cassel, and found to his surprise that it was conferred upon himself. The elder Förster, however, was soon provided for elsewhere, being appointed professor of natural history at Halle. At Cassel Förster formed an intimate friendship with the great anatomist Sömmering, and about the same time made the acquaintance of Jacobi, who gave him a leaning towards mysticism from which he subsequently emancipated himself. The want of books and scientific apparatus at Cassel induced him to resort frequently to Göttingen, where he became betrothed to Therese Heyne, the daughter of the illustrious philologist, a clever and cultivated woman, but ill-suited to be Förster's wife. To be able to marry he accepted (1784) a professorship at the university of Wilna, which he did not find to his taste. The penury and barbarism of Polish circumstances are graphically described in his and his wife's letters of this period. After a few years' residence at Wilna he resigned his appointment to participate in a scientific expedition which was organized by the Russians in this year, and upon the relinquishment of this undertaking became librarian to the elector of Mainz. He actively promoted the incorporation of the left bank of the Rhine with France and in 1793 went to Paris to carry on the negotiations. Meanwhile, however, the Germans seized Mainz, and Förster—already disheartened by the turn of events in France—was cut off from all return. Domestic sorrows were added to his political troubles and he died suddenly at Paris on the 10th of January 1794.
FORSTER, J.—FORSTER, W. E.

Forster’s masterpiece is his Ansichten vom Niederrhein, von Brabant, Flandern, Holland, England und Frankreich (1791-1794), one of the ablest books of travel of the 18th century. His style is clear and vivid; his method of describing what he sees extraordinarily plastic; above all, he has the art of presenting objects to us from their most interesting and attractive side. The same qualities are also more or less conspicuous in his minor writings. By his translation (from the English) of the Souvenirs de la Vie de Voltaire (1791), he first awakened German interest in Indian literature.

Forster’s Sämtliche Werke appeared at Leipzig in 9 vols. in 1843. The Ansichten vom Rhein, &c., has been frequently reprinted (best edition by A. Leitzmann, Halle, 1893); Leitzmann has also published (Stuttgart, 1894) a selection of Forster’s Kleine Schriften, which originally appeared in 6 vols. (1780-1781). His Briefwechsel mit Sämmerring by H. Hetterm (Brunswick, 1877). See J. Moleschoff, G. Forster, der Krankenfürsorfer des Volks (1854; 2nd ed., 1874); K. Klein, G. Forster in Mainz (Gotha, 1863); A. Leitzmann, G. Forster (Vorlesung) (Halle, 1893).

FORSTER, JOHN (1812-1876), English biographer and critic, was born on the 2nd of April 1812 at Newcastle. His father, who was a Unitarian and belonged to the junior family of a good Northumberland family, was a cattle-dealer. After being well grounded in classics and mathematics at the grammar school of his native town, John Forster was sent in 1828 to Cambridge, but after only a month’s residence he removed to London, where he attended classes at University College, and was entered at the Inner Temple. He devoted himself, however, chiefly to literary pursuits. He contributed to The True Sun, The Morning Chronicle and to The Examiner, for which he acted as literary and dramatic critic; and the influence of his powerful individuality soon made itself felt. His Lives of the Statesmen of the Commonwealth (1836-1839) appeared partly in Lardner’s Cyclopaedia. He published the work separately in 1840 with a Treatise on the Popular Progress in English History. Its merits obtained immediate recognition, and Forster became a prominent figure in that distinguished circle of literary men which included Bulwer, Talbot, Albany, Fonblanque, Landor, Carlyle and Dickens. Forster is said to have been for some time engaged to Letitia Landon, but the engagement was broken off, and Miss Landon married George Maclean. In 1843 he was called to the bar but he never became a practising lawyer. For some years he edited the Foreign Quarterly Review; in 1846, on the retirement of Charles Dickens, he took charge for some months of the Daily News; and from 1847 to 1856 he edited the Examiner. From 1836 onwards he contributed to the Edinburgh Quarterly and Foreign Quarterly Review a variety of articles, some of which were republished in two volumes of Biographical and Historical Essays (1858). In 1858 appeared his admirable Life and Times of Oliver Goldsmith (revised in 1854). Continuing his researches into English history under the early Stuarts, he published in 1860 the Arrest of the Five Members by Charles I.—A Chapter of English History rewritten, and The Debates on the Grand Remonstrance, with an Introductory Essay on English Freedom. These were followed by his Sir John Eliot: A Biography (1864), elaborated from one of his earlier studies for the Life of the Right Hon. Sir John Eliot (Longman’s American Edition of Landor), and, on the death of his friend Alexander Dyer, Forster undertook the publication of his third edition of Shakespeare. For several years he had been collecting materials for a life of Swift, but he interrupted his studies in this direction to write his standard Life of Charles Dickens. He had been long intimate with the novelist, and it is by this work that John Forster is now chiefly remembered. The first volume appeared in 1872, and the biography was completed in 1874. Towards the close of 1873 the first volume of his Life of Swift was published; and he had made some progress in the preparation of the second at the time of his death on the 2nd of February 1876. In 1855 Forster had been appointed secretary to the lunacy commission, and from 1861 to 1872 he held the office of a commissioner in lunacy. His valuable collection of manuscripts, including the original copies of Charles Dickens’s novels, together with his books and pictures, was bequeathed to South Kensington Museum.

An admirable account of him by Henry Morley is prefixed to the official handbook (1877) of the Dyce and Forster bequests.

FORSTER, JOHN COOPER (1823-1886), British surgeon, was born in 1823 in Lambeth, London, where his father and grandfather before him had been local medical practitioners. He entered Guy’s hospital in 1833, was appointed demonstrator of anatomy in 1835, assistant-surgeon, 1845, and surgeon, 1870. He became a member of the College of Surgeons in 1844, fellow in 1849 and president in 1884. He was a prompt and sometimes bold operator. In 1858 he performed practically the first gastrosotomy in England for a case of cancer of the oesophagus. Among his best-known papers were discussions of acquisperey, syphilis, hydrophobia, intestinal obstruction, modified obturator hernia, torsion, and colloid cancer of the large intestine; and he published a book on Surgical Diseases of Children in 1860, founded on his experience as surgeon to the hospital for children and women in Waterloo Road. He died suddenly in London on the 2nd of March 1886.

FORSTER, WILLIAM EDWARD (1818-1886), British statesman, was born of Quaker parents at Bradpole in Dorsetshire on the 11th of July 1818. He was educated at the Friends’ school at Tottenham, where his father’s family had long been settled, and on leaving school he was put into business. He declined, however, on principle, to enter a brewery. Becoming in due time a woolen manufacturer in a large way at Bradford, Yorkshire (from which after his marriage he moved to Bury-in-Wharfedale), he soon made himself known as a practical philanthropist. In 1846-1847 he accompanied his father to Ireland as distributor of the Friends’ relief fund for the famine in Connemara, and the state of the country made a deep impression on him. In 1849 he wrote a preface to a new edition of Clarkson’s Life of William Penn, defending the Quaker statesman against Macaulay’s criticisms. In 1850 he married Jane Martha, eldest daughter of the famous Dr Arnold of Rugby. She was not a Quaker, and her husband was formally excommunicated for marrying her, but the Friends who were commissioned to announce the sentence “shook hands and stayed to luncheon.” Forster thereafter ranked himself as a member of the Church of England, for which, indeed, he was in later life charged with having too great a partiality. There were no children of the marriage, but when Mrs Forster’s brother, William Arnold, died in 1859, leaving four orphans, the Forsters adopted them as their own.

One of these children was Mr H. O. Arnold-Forster (1855-1900), the well-known Liberal-Unionist member of parliament, who eventually became a judge of the Queen’s Bench (he was secretary to the admiralty (1900-1903), and was the author of numerous educational books published by Cassell & Co., of which firm he was a director.

W. E. Forster gradually began to take an active part in public affairs by speaking and lecturing. In 1858 he gave a lecture before the Leeds Philosophical Institution on “How we Tax India.” In 1859 he stood as Liberal candidate for Leeds, but was beaten. But he was highly esteemed in the West Riding, and in 1862 he was returned unopposed for Halifax. In 1865 (unopposed) and in 1868 (at the head of the poll) he was again returned. He took a prominent part in parliament in the debates on the American Civil War, and in 1868 was made under-secretary for the colonies in Earl Russell’s ministry. It was then that he first became a prominent advocate of imperial federation. In 1866 his attitude on parliamentary reform attracted a good deal of attention. His speeches were full of knowledge of the real condition of the people, and contained something like an original programme of radical legislation. “We have other things to do,” he said, “besides extending the franchise— I mean the dangerous class in our large towns. We want to see
whether we cannot make for the agricultural labourer some better hope than the workhouse in his old age. We want to have Old England as well taught as New England." In these words he heralded the education campaign which occupied the country for so many years afterwards. Directly the Reform Bill had passed, the necessity of "inducing our masters to learn their business, and our servants" (another by no means unambitious phrase) became pressing. Mr. Forster and Mr. Cardwell, as private members in opposition, brought in Education Bills in 1867 and 1868; and in 1868, when the Liberal party returned to office, Mr. Forster was appointed vice-president of the council, with the duty of preparing a government measure for national education. The Elementary Education Bill (see EDUCATION) was introduced on the 17th of February 1870. The religious difficulty at once came to the front. The Manchester Education Union and the Birmingham Education League had already formulated in the provinces the two opposite theories, the former standing for the preservation of denominational interests, the latter advocating secular rate-aided education as the only means of protecting Nonconformity against the Church. The Dissenters were by no means satisfied with Forster's "conscience clause" as contained in the bill, and they regarded him, the ex-Quaker, as a deserter from their own side; while they resented the "25th clause," permitting school boards to pay the fees of needy children at denominational schools out of the rates, as an insidious attack upon themselves. By the 14th of March, when the second reading came on, the controversy had assumed threatening proportions; and Mr. Dixon, the Liberal member for Birmingham and chairman of the Education League, moved an amendment, the effect of which was to prohibit all religious education in board schools. The government made its rejection a question of confidence, and the amendment was withdrawn; but the result was the insertion of the Cowper-Temple clause as a compromise before the bill passed. Extremists on both sides abused Forster, but the government had a difficult set of circumstances to deal with, and he acted like a prudent statesman in condemning himself when he could get. An ideal bill was impracticable; it is to Forster's enduring credit that the bill of 1870, imperfect as it was, established at last some approach to a system of national education in England without running absolutely counter to the most cherished English ideas and without ignoring the principal agencies already in existence.

Forster's next important work was in passing the Ballot Act of 1872, but for several years afterwards his life was uneventful. In 1874, he was again returned for Bradford, in spite of Dissenting attacks, and he took his full share of the work of the Opposition Front Bench. In 1875, when Mr. Gladstone retired, he was strongly supported for the leadership of the Liberal party, but declined to be nominated against Lord Hertington. In the same year he was elected F.R.S., and made lord rector of Aberdeen University. In 1876, when the Eastern question was looming large, he visited Servia and Turkey, and his subsequent speeches on the subject were marked by studious moderation, distasteful to extremists on both sides. On Mr. Gladstone's return to office in 1880 he was made chief secretary for Ireland, with Lord Cowper as lord lieutenant. He carried the Compensation for Disturbance Bill through the Commons, only to see it thrown out in the Lords, and his task was made more difficult by the agitation which arose in consequence. During the gloomy autumn and winter of 1880-1881 Forster's energy and devotion in grappling with the situation in Ireland (see IRELAND) were indefatigable, his labour was enormous, and the personal risks he ran were many; but he enjoyed the Irish character in spite of it. His enemies, as one of his biographers has observed, are the only people to whom he would have given genuine admiration in all his coadjutors. On the 24th of January 1882 he introduced the Coercion Bill in the House of Commons, to deal with the growth of the Land League, and in the course of his speech declared it to be "the most painful duty" he had ever had to perform, and one which would have prevented his accepting his office if he had known that it would fall upon him. The bill passed, among its provisions being one enabling the Irish government to arrest without trial persons "reasonably suspected" of crime and conspiracy. The Irish party used every opportunity in and out of parliament for resenting this act, and Forster was kept constantly on the move between Dublin and London, conducting his campaign against crime and anarchy and defending it in the House of Commons. His scrupulous conscientiousness and anxiety to meet every reasonable claim availed him nothing; he was made a scapegoat, and the strain was intolerable. He was nicknamed "Buckshot," by the Nationalist press, on the supposition that he had ordered its use by the police when firing on a crowd. On the 13th of October Mr. Parnell was arrested, and on the 20th the Land League was proclaimed. From that time Forster's life was in constant danger, and he had to be escorted by mounted police when he drove in Dublin. Early in March 1882 he visited some of the worst districts in Ireland, and addressed the crowd at Tullamore on the subject of outrages, denouncing the people for their want of courage in not assisting the government, but adding, "whether you do or not, it is the duty of the government to stop the outrages, and stop them we will." Forster's pluck in speaking out like this was fully appreciated in England, but it was not till after the revelations connected with the Phoenix Park murders that the dangers he had confronted were properly realized, and it became known that several plans to murder him had only been frustrated by the merest accidents. On the 2nd of May Mr. Gladstone announced that the government intended to release Mr. Parnell and his fellow-prisoners in Kilmainham, and that both Lord Cowper and Mr. Forster had in consequence resigned; and the following Saturday Forster's successor, Lord Frederick Cavendish, was, with Mr. Burke, murdered in Phoenix Park. It was characteristic of the man that Forster at once offered to go back to Dublin temporarily as chief secretary, but the offer was declined. His position naturally attracted universal attention towards him, particularly during the debates which ensued in parliament on the "Kilmainham Treaty." But Mr. Gladstone's influence with the Liberal party was paramount, in spite of the influence of the Irish government, and speaking for himself Forster's pointed criticisms only caused thoroughly good-natured people to accuse him of a desire to avenge himself. It was not till the next session that he delivered his fiercest attack on Parnell in the debate on the address, denouncing him for his connexion with the Land League, and quoting against him the violent speeches of his supporters and the articles of his newspaper organs. It was on this occasion that Parnell, on Forster's charging him, not with directly planning or perpetrating outrages or murder, but with conniving at them, ejaculated "why lie?" and, replyng on the next day, the Irish leader, instead of disproving Forster's charges, bitterly denounced his methods of administration. Though, during the few remaining years of his life, Forster's political record covered various interesting subjects, his connexion with these stormy times in Ireland throws them all into shadow. He died on the 6th of April 1886, on the eve of the introduction of the Home Rule Bill, to which he was stoutly opposed. In the interval there had been other questions on which he found himself at variance with Gladstonian Liberalism, for instance, as regards the Sudan and the Transvaal, nor was he inclined to stomach the claims of the Caucus or the Birmingham programme. When the Redistribution Act divided Bradford into three constituencies, Forster was returned for the central division, but he never took his seat in the new parliament. Forster, like John Bright, was an excellent representative of the English middle-class in public life. Patriotice, energetic, independent, incorruptible, shrewd, fair-minded, he was endowed not only with great sympathy with progress, but also with a full faculty for resistance to mere democracy. He was tall (the Yorkshiremen called him "Long Forster") and sturdily, if stiffly, built, and, with his simple tastes and straightforward manners and methods, was a typical North-country figure. His oratory was rough and unpolished, but full of freshness and force and genuine feeling. It was Forster who, when appealing to the government at the time of Gordon's danger at Khartum, spoke of Mr. Gladstone as able to "persuade most people of most things, and himself of almost anything," and though the phrase
was much resented by Mr Gladstone's entourage, the truth that underlay it may be taken as representing the very converse of his own character. His personal difficulties with some of his colleagues, both in regard to the Education Act of 1870 and his Irish administration, must be properly understood if a complete comprehension of his political career is to be obtained. For an account of them we need only refer to the Life of the Right Hon. P. T. Fothergill, MP, by his personal acquaintance (1876).

**FORSYTH, Peter Taylor** (1848– ), British Non-conformist divine, was born at Aberdeen in 1848. He took first-class honours in classics at Aberdeen, subsequently studied at Gottingen (under Ritschl) and at New College, Hampstead, and entered the Congregational ministry. Having held pastorates at Shipley, Hackney, Manchester, Leicester and Cambridge, he became principal of Hackney Theological College, Hampstead, in 1901. In 1907 he delivered the Lyman Beecher lectures on preaching at Yale University, published as *Positive Preaching and Modern Mind*. Among his other publications may be mentioned *Religion in Recent Art*, and articles in the *Contemporary Review, Hibbert Journal*, and *London Quarterly*. He was chairman of the Congregational Union of England and Wales in 1905.

**FORTALEZA** (usually called *Ceará* by foreigners), a city and port of Brazil and the capital of the state of Ceará, on a crescent-shaped indentation of the coast-line immediately W. of Cape Mucuripe or Mocorpe, 71 m. from the mouth of the Ceará river, in lat. 3° 42' S., long. 38° 30' W. Pop. (1890) of the municipality, including a large rural district, 40,902. The city sits on a plateau overlooking the river, and is regularly laid out, with broad, well-paved, gas-lighted streets and numerous squares. Owing to the aridity of the climate the vegetation is less luxuriant than in most Brazilian cities. The temperature is usually high, but it is modified by the strong sea winds. Fortaleza has suffered much from epidemics of yellow-fever, small-pox and beri-beri, but the climate is considered to be healthy. A small branch of the Ceará river, called the Pajéhú, traverses the city and divides it into two parts, that on its right bank being locally known as Outero. Fortaleza is the see of a bishopric, created in 1854, but it has no cathedral, one E. C. Church being used for that purpose. Its public buildings include the government house, legislative chambers, bishop's palace, an episcopal seminary, a lyceum (high school), Misericordia hospital, and asylums for mendicants and the insane. The custom-house stands near the seashore, 1½ m. from the railway station in the city, with which it is connected by rail. The port is the principal outlet for the products of the state, but its anchorage is an open roadstead, one of the most dangerous on the northern coast of Brazil, and all ships are compelled to anchor well out from shore and discharge into lighter craft. Improvements in the harbour have been made by Mr John Haskew and two of his sons, who have been under construction for many years, but have made very slow progress. The Baturité railway, built by the national government partly to give employment to starving refugees in times of long-continued droughts, connects the city and its port with fertile regions to the S.W., and extends to Senador Pompeu, 175 m. distant. The exports include sugar, coffee, rubber, cotton, rice, beans, fruits, hides and skins.

Fortaleza had its origin in a small village adjoining a fort established at this point in early colonial times. In 1655 it took the name of Villa do Forte da Assumpção, but it was generally spoken of as Fortaleza. In 1810 it became the capital of Ceará, and in 1823 it was raised to the dignity of a city under the title of Fortaleza da Nova Bragança.

**FORT AUGUSTUS**, a village of Inverness-shire, Scotland. Pop. (1901) 706. It is delightfully situated at the south-western extremity of Loch Ness, about 30 m. S.W. of Inverness, on the rivers Oich and Tarff and the Caledonian Canal. A branch line connects with Spean Bridge on the West Highland railway via Inverness. The fort has been called Kiltchumhan, was built in 1716 for the purpose of keeping the Highlanders in check, and was enlarged in 1730 by General Wade. It was captured by the Jacobites in 1745, but reoccupied after the battle of Culloden, when it received its present name in honour of William Augustus, duke of Cumberland, the victorios general. The fort was used as a sanatorium until 1857, when it was bought by the 12th Lord Lovat, whose son presented it in 1876 to the English order of Benedictines. Within four years there rose upon its site a pile of stately buildings under the title of St Benedict's Abbey and school, a monastic and collegiate institution intended for the higher education of the sons of the Roman Catholic nobility and gentry. The series of buildings consists of the college, monastery, hospice and scriptorium—the four forming a quadrangle connected by beautiful cloisters. Amongst its benefactors were many Catholic Scots and English peers and gentlemen whose arms are emblazoned on the windows of the spacious refectory hall. The summit of the college tower is 110 ft. high.

**FORT DODGE**, a city and the county-seat of Webster county, Iowa, U.S.A., on the Des Moines river, 83 m. by rail N. by W. from Des Moines. Pop. (1890) 4871; (1900) 12,162; (1905, state census) 14,301, (1909 being foreign-born) (1910) 15,543. It is served by the Illinois Central, the Chicago Great Western, the Minneapolis & Saint Louis, and the Fort Dodge, Des Moines & Southern railways, the last an electric interurban line. Eureka Springs and Wild Cat Cave are of interest to visitors, and attractive scenery is furnished by the river and its bordering bluffs. The river is here spanned by the Chicago Great Western railway steel bridge, or viaduct, one of the longest in the country. Fort Dodge is the seat of Tobin College (420 students in 1907-1908), a commercial and business school, with preparatory, normal and collegiate departments, and courses in oratory and music; among its other institutions are St. Paul's school (Evangelical Lutheran), two Roman Catholic schools, Corpus Christi Academy and the Sacred Heart school, Our Lady of Lourdes convent and a Carnegie library. Oleson Park and Reynolds Park are the city's principal parks. Immediately surrounding Fort Dodge is a rich farming country. To the E. of the city lies a gypsum bed, extending over an area of about 50 sq. m., and considered to be the most valuable in the United States; to the S. coal abounds; there are also limestone quarries and deposits of clay in the vicinity—the clay being, for the most part, obtained by mining. Fort Dodge, a market for the products of the surrounding country, and is a shipping centre of considerable importance. It has various manufactures, including gypsum, plaster, oatmeal, brick and tile, sewer pipe, pottery, foundry and machine-shop products, and shoes. In 1905 the value of all the factory products was $3,025,500, an increase of 200-5% over that of 1900. Fort Clark was erected on the site in 1830 to protect settlers against the Indians; in 1851 the name was changed by order of the secretary of war to Fort Dodge in honour of General Henry Dodge (1782-1867), who was a lieutenant-colonel of Mississippi Volunteers in the Mexican War of 1846-1848, served with distinction as a colonel of Michigan Mounted Volunteers in the Black Hawk War, resided from the military service in March 1833, was governor of Wisconsin Territory from 1836 to 1841 and from 1846 to 1848, and was a delegate from Wisconsin Territory to Congress from 1841 to 1845, and a United States senator from Wisconsin in 1848-1857. The fort was abandoned in 1853, and in 1854 a town was laid out. It was chartered as a city in 1866. From the gypsum beds to the west of the fort Dodge was taken in 1868 the block of gypsum from which was modelled the "Cardiff Giant," a rudely-fashioned human figure, which was buried near Cardiff, Onondaga county, New York, where it was "discovered" late in 1865. It was then exhibited in various parts of the country as a "petrified man." The hoax was finally exposed by Professor Othniel C. Marsh of Yale; and George Hall of Binghamton, N.Y., confessed to the fraud, his object having been to discredit belief in the "giants" of Genesis vi. 4. (See "The Cardiff Giant: the True Story of a Remarkable Deception," by Andrew D. White, in the *Century Magazine*, vol. xlii., 1903.)

**FORT EDWARD**, a village of Washington county, New York, U.S.A., in the township of Fort Edward, on the Hudson river, 56 m. by rail N. of Albany. Pop. of the village (1900) 3521, of whom 385 were foreign-born; (1905) 3866; (1910) 3762; of
the township, including the village (1900), 5216; (1905, 5300; (1910) 5740. The village lies mostly at the foot of a steep hill, is at the junction of the main line and the Glens Falls branch of the Delaware & Hudson railway, and is served by electric lines to Albany and Glens Falls; the large canal connecting Lake Champlain and the Hudson river enters the Hudson here. The river furnishes good water-power, which is used in the manufacture of paper and wood pulp, the leading industry. Shirts and pottery (lower pots, jars and drain tile) are manufactured also. The village is the seat of the Fort Edward Collegiate Institute, a non-sectarian school for girls, which was founded in 1854 and until 1893 was coeducational. The village owns and operates the waterworks. Indian war parties on their way to the Ohio met onustomably to partake of refreshments and proteins. As a port of call, the head of navigation for small boats on the Hudson, to Lake George or Lake Champlain, and hence it was known as the Great Carrying Place. Governor (afterwards Sir) Francis Nicholson in 1709, in his expedition against Canada, built here a stockade which was named Fort Nicholson. Some years afterwards John Henry Lydius (1693-1791) established a settlement and protected it by a new fort, named Fort Lydius, but this was destroyed by the French and Indians in 1745. In 1755, a third fort was built by General Phineas Lyman (1716-1774), who commanded the expedition against Crown Point under General William Johnson, and was named Fort Lyman; in 1756 Johnson renamed it Fort Edward in honour of Edward, Duke of York. In the War for Independence Fort Edward was the headquarters of General Philip Schuyler while he and his troops were blocking the march of General Burgoyne's army from Fort Ticonderoga. When a part of Burgoyne's forces was distant only 3 or 4 m. from Fort Edward, on Fort Edward Hill, on the 27th of July 1777, the leader of an Indian band whose assurance the British had sought is supposed to have murdered Jane McCrea (c. 1757-1777), a young girl who had been visiting friends in Fort Edward, and who was to be escorted on that day to the British camp and there to be married to David Jones, a loyalist serving as a lieutenant in Burgoyne's army; it is possible that she was shot accidentally by Americans pursuing her Indian escorts, but her death did much to rouse local sentiment against Burgoyne and his Indian allies, and caused many volunteers to join the American army resisting Burgoyne's invasion. A monument has been erected by the Jane McCrea Chapter of the Daughters of the American Revolution near the spot where she was killed, and she is buried in Union Cemetery in Fort Edward.

Fort Edward township was erected in 1818 from a part of the township of Argyle. Fort Edward village was incorporated in 1822.

See R. O. Bascom, The Fort Edward Book (Fort Edward, 1903).

FORTESCUE, SIR JOHN (c. 1534-c. 1579), English lawyer, the second son of Sir John Fortescue, of an ancient family in Devonshire, was born at Norris, near South Brent, in Somersetshire. He was educated at Exeter College, Oxford. During the reign of Henry VI., he was three times appointed one of the governors of Lincoln's Inn. In 1441 he was made a king's sergeant at law, and in the following year chief justice of the king's bench. As a judge Fortescue is highly recommended for his wisdom, gravity and uprightness; and he seems to have enjoyed great favour with the king, who is said to have given him some substantial proofs of esteem and regard. He held his office during the remainder of the reign of Henry VI., to whom he steadily adhered; and having faithfully served that unfortunate monarch in all his troubles, he was attainted of treason in the first parliament of Edward IV. When Henry subsequently fled into Scotland, he is supposed to have accompanied him in his flight, chancellor of England. In 1463 Fortescue accompanied Queen Margaret and her court in their exile on the Continent, and returned with them afterwards to England. During their wanderings abroad the chancellor wrote for the instruction of the young prince Edward his celebrated work De laudibus legum Angliae. On the defeat of the Lancastrian party he made his submission to Edward IV., from whom he received a general pardon dated Westminster, October 13, 1471. He died at an advanced age, but the exact date of his death has not been ascertained.

Fortescue’s masterly vindication of the laws of England, though received with great favour by the learned of the profession to whom it was communicated, did not appear in print until the reign of Henry VIII., when it was published, but without a date. It was subsequently many times reprinted. Another valuable and learned treatise on the laws of England, with observations on the statute of the title of The Difference between an Absolute and a Limited Monarchy. In the Cotton library there is a manuscript of this work, in the title which appears to have been added to the Henry VI. edition, but in many passages the word Henry has been inserted for Edward. IV. A revised edition of this work, with a very valuable historical and biographical introduction, was published in 1853 by Charles Plummer, under the title of Fortescue’s In the Commonwealth. English & Welsh writings appear in The Works of Sir John Fortescue, now first Collated and Arranged, published in 1869 for private circulation, by his descendant, Lord Clermont.

FORTESCUE, SIR JOHN (c. 1531-1607), English statesman, was the eldest son of Sir Adrian Fortescue (executed in 1539), and of his second wife, Anne, daughter of Sir William Reade or Rode of Borsall in Buckinghamshire. The exact date of his birth is not recorded, but we are told that he was married to his estate at Shirburn in Oxfordshire in 1551. Through his father’s mother, Alice, daughter of Sir Geoffrey Boleyn, he was a second cousin once removed from Queen Elizabeth. He acquired early a considerable reputation as a scholar and was chosen to direct the Princess Elizabeth’s classical studies in Mary’s reign. On the accession of Elizabeth he was appointed keeper of the great wardrobe. He was returned in 1572 to parliament for Wallingford, in 1586 for Buckingham borough, in 1588 and 1597 for Buckingham county, and in 1601 for Middlesex. In 1589 he was appointed chancellor of the exchequer and a member of the privy council. In 1592 he was knighted, and in November 1601, in addition to his two great offices, he received that of chancellor of the duchy of Lancaster. By means of his lucrative employments he amassed great wealth, with which he bought large estates in Oxfordshire and Buckinghamshire, and kept up much state and a large household. He took a prominent part in public business, was a member of the court of the star chamber and an ecclesiastical commissioner, sat on various important commissions, and as chancellor of the exchequer explained the queen’s business in the House of Lords and the House of Commons, and conducted the queen’s business in parliament. On the death of Elizabeth he suggested that certain taxes should be imposed on James’s powers, in order probably to limit the appointment of Scotchmen to office, but his advice was not followed. He was deprived by James of the chancellorship of the exchequer, but evidently did not forfeit his favour, as he retained his two other offices and entertained James several times at Henden and Selden. In 1604 Sir John, who stood for Buckinghamshire, was defeated by Sir Francis Goodwin, whose election, however, was declared void by the lord chancellor on the ground of a sentence of outlawry under which he lay, and Fortescue was by a second election returned in his place. This incident gave rise to a violent controversy, regarding the chancellor’s jurisdiction in deciding disputed elections to parliament, which was repudiated by the Commons but maintained by the king. The matter after much debate was ended by a compromise, which, while leaving the principle unsettled, set aside the elections of both candidates and provided for the issue of a new writ. Fortescue was then in February 1606 returned for Middlesex, which he represented till his death on the 23rd of December 1607. He died buried in Muresby church in Buckinghamshire, where a monument was erected to his memory. His long public life was highly honourable, and he served his sovereign and country with unwavering fidelity and honesty. His learned attainments too were considerable—Camden styles him “vir integer, Graece, ed. 1

The inscription on his tomb states that he was 76 at his death on the 23rd of December 1607 (Lord Clermont’s Hist. of the Family of Fortescue, 377), but according to a statement ascribed to himself, he was in the same year as Queen Elizabeth and therefore in 1533 (Bucks. Architect. and Archaeol. Soc. Records of Bucks, p. 888).

1 David Lloyd’s State Worthies (1679), 550.
Latinique apprime eruditus,1 and his scholarship is also praised by Lloyd, while his friendship with Sir Thomas Bodley procured gifts of books and manuscripts to the latter's library. Fortescue married (i) Cecily, daughter of Sir Edmund Ashfield of Ewelme, by whom, besides a daughter, he had two sons, Sir Francis and Sir William; and (2) Alice, daughter of Christopher Smyth of Annabels in Hertfordshire, by whom he had one daughter. His Black coats of arms bear the line he bore after the death of Sir John Fortescue, 3rd baronet, in 1717.

FORTEVIO, a village and parish of Perthshire, Scotland, on the Water of May, a right-hand affluent of the Earn, 61 m. S.W. of Perth. Pop. of parish (1901) 562. It is a place of remote antiquity, having been a capital of the Picts, when the district was known as Forren, and afterwards of the Scots. The army led by Edward Balliol camped here before the battle of Dupplin (1332), in which the regent, Donald, earl of Mar, was slain along with 13,000 out of 30,000 men. The parish of Findo-Gask adjoining it on the N.W. contains remains of a Roman road, station and outpost, besides the "ancient fort" of Gask, and the present name was formed which forms the theme of one of her most popular songs. The new house in which she died dates from 1801.

FORT GEORGE, a military station of Inverness-shire, Scotland. It lies 12 m. N.E. of Inverness, and is the terminus of the small branch line connecting with the Highland railway at Gollanfield junction. It occupies a sandy promontory forming the extreme end of the southern shore of Inner Moray Firth (also called the Firth of Inverness), which is here only 1 m. wide. There is communication by ferry with Fortrose on the opposite coast of the Black Isle. The fort was begun in 1748, partly after the plan of one of Vauban's works, and named in honour of George II. Wolfe, who saw it in course of erection in 1751, was much impressed with it and thought it would, when finished, be "the most considerable fortress and best situated in Great Britain." It covers 16 acres and contains accommodation for nearly 2500 men. It is the depot of the Seaforth Highlanders, and a military training-ground of some size and importance because the surrounding country gives ample facilities for exercise and manoeuvres. General Wade's road is maintained in good order. Fort George is the obstacle of a line of fortifications which, according to the Barons Nevis, is said almost been closed to the Edinburgh with the withdrawal of the above service. He put forward. About 2 m. S.E. is the fishing village of Campbeltown, in growing repute as a seaside resort. Midway between the fort and Inverness stands Castle Stuart, a shooting-box of the earl of Moray.

FORTH, a river and firth of the east of Scotland. The river is formed by two head streams, Duchray Water (12 m.) and Avondhu (10 m.), or Laggan as it is called after it leaves Loch Ard, both rising in the north-east of Ben Lomond in Stirlingshire, and the other stream is the tributary of Aberfeldy. The river receives the Kely, the Forth continues to be a Perthshire stream, but afterwards it becomes the dividing line between the counties of Perth and Stirling as far as the confluence of the Allan. Thence it belongs to Stirlingshire to a point 1 1/2 m. due west of Cambus, whence it serves as the boundary between the shires of Stirling and Clackmannan. Owing to the extremely tortuous character of its course between Garmore and Alloa—the famous 1 links of the Forth,2—the actual length of the river is 66 m., or nearly double the distance in a direct line (50 m.) between the source of the Duchray and the confluence, where the firth begins. The river drains an area of 645 sq. m. Its general direction is mainly easterly with a gentle trend towards the south, and the principal tributaries on the left are the Goodie, Teith, Allan and Devon, and on the right, the Kely, Boquhan and Bannock. The alluvial plain extending from Garmore to the county town is called the Carse of Stirling. The places of interest on the banks are Aberfoyle, Kippen, Stirling, Cambuskenneth, Alloa and Kincardine, but after it crosses the Highland line the Forth does not present many passages of remarkable beauty. There are ferries at Aberfoyle, Stirling and Stirling (2), besides railway viaducts at Stirling and Alloa, and there are ferries at Stirling (for Cambuskenneth), Alloa (for South Alloa) and Kincardine (for Alloa). The tide rises to 44 ft. above Stirling, where the river is navigable at high water by vessels of 100 tons. There is, however, a brisk shipping trade at Alloa, where the dock accommodates vessels of at least 300 tons.

The Firth of Forth extends from Kincardine to the North Sea, that is, to an imaginary line drawn, just west of the Isle of May, from the East Neuk of Fife to the mouth of the Tyne in Haddington—\textit{a distance of 49 m. Thus, according to some calculations, the Forth measures from source to sea 114 m. The width of the firth varies from \textit{3} m. at Kincardine and \textit{1} \textit{3} m. at Queensferry to \textit{6} m. at Leith and \textit{1} \textit{7} m. at the mouth. The chief affluents are, on the south, the Carron, Avon, Almond, Leith, Esk and Tyne, and on the north, the Tiel, Leven, Kiel and Dreel. The principal ports on the south shore are Grangemouth, Bo'ness, Granton and Leith, and on the north, Burntisland and Kirkcaldy; but fishery centres and holiday resorts are very numerous on both coasts. Since the opening of the Forth Bridge (see Bridges) in 1890 the ferries at Queensferry and Burntisland have been much diminished, and the trade of the fishing fleet is still considerable, though the oyster trade is dwindling. The larger islands are Inchcolm, with the ruins of an abbey, Inchkeith, with fortifications and a lighthouse, and the Isle of May, with a lighthouse. The anchorage of St Margaret's Hope, with the naval base of Rosyth, lies off the shore of Fife immediately to the west of the Forth Bridge.

The Forth was the Bodotria of Tacitus and the Scots Water of the chroniclers of the 11th and 12th centuries; while Bede (d. 735) knew the firth as Sinus orientalis (the Eastern Gulf), and Nennius (fl. 760) as Mare Praetunicum (the Frisian Sea).

FORTIFICATION AND SIEGECRAFT. "Fortification" is the military art of strengthening positions against attack. The word (Lat. \textit{fortis}, strong, and \textit{facere}, to make) implies the creation of defences. Thus the boy who from the top of a mound defies his comrades, or shelters from their snowballs behind a fence, is merely taking advantage of ground; but if he puts up a hurdle on his mound and stands behind that he has fortified his position. Fortification consists of two elements, viz. \textit{protection} and \textit{obstacle}. The protection shields the defender from the enemy's fire; the obstacle denies the enemy from coming to close quarters, and delays him under fire.

Protection may be of several kinds, direct or indirect. Direct protection is given by a wall or rampart of earth, strong enough to stop the enemy's missiles. The value of this is reduced in proportion as the defender has to expose himself to return the enemy's fire, or to resist his attempts to destroy the defences. Indirect protection is given by \textit{distance}, as for instance by a high wall placed on a cliff so that the defender on the top of the wall is out of reach of the enemy's missiles if these are of short range, and he can thus drive them off with the aid of missiles of his own. As the missiles are air, and air is everywhere, the protection is always available, though it decreases in immediate effect. In the middle ages, the medieval engines were few in number, and the effect of a single salvo of arrows could be felt for some distance. In the present day the same object is attained by pushing out detached forts to such a distance from the town they are protecting that the besieger cannot bombard the town as long as he is outside the forts. Another form of indirect protection of great importance is \textit{concealment}.

The obstacle may consist of anything which will impede the enemy's advance and prevent him from coming to close quarters. In the earliest forms of fortification the protecting wall was also the obstacle, or it may be a wet or dry ditch, an entanglement, a swamp, a horn hedge, a spiked palisade, or some temporary expedient, such as crows' feet or chevaux de frise. The two elements must of course be arranged in combination. The besieged must be able to defend the obstacle from their protected position, otherwise it can be surmounted or destroyed at leisure. But a close connexion is no longer essential. The effect of modern
FORTIFICATION AND SIEGECRAFT

I. HISTORY

The most elementary type of fortification is the thorn hedge, a type which naturally recurs from age to age under primitive conditions. Thus, Alexander found the villages of the Hyrcanians defended by thick hedges, and the same arrangements may be seen to-day among the least civilized tribes of Africa. The next advance from the hedge is the bank of earth, with the exterior made steep by revetments of sods or hurdle-work. This has a double advantage over the hedge, as, besides being a better obstacle against assault, it gives the defenders an advantage of position in a hand-to-hand fight. Such banks formed the defences of the German towns in Caesar's time, and they were constructed with a high degree of skill. Timber being plentiful, the parapets were built of alternate layers of stones, earth and tree trunks. The latter were built in at right angles to the length of the parapet, and were thus very difficult to displace, while the earth prevented their being set on fire. The bank was often strengthened by a palisade of tree trunks or hurdle-work.

After the bank the most important step in advance for a common people was to lower the wall as far below the level of the ground as possible. This was done by constructing it of a material that could not readily be undermined; brick or mud. The history of the development of the wall and of the methods of attacking it is the history of fortification for several thousand years.

The first necessity for the wall was height, to give security against escalade. The second was thickness, so that the defenders might have a platform on the top which would give them space to circulate freely and to use their weapons. A lofty wall, thick enough at the top for purposes of defence, would be very expensive if built of solid masonry; therefore the plan was early adopted of building two walls with a filling of earth or rubble between them. The face of the outer wall would be carried up a few feet above the platform, and crenelated to give protection against arrows and other projectiles.

The next forward step for the defence was the construction of towers at intervals along the wall. These provided flanking fire along the front; they also afforded refuges for the garrison in case of a successful escalade, and from them the platform could be enfiladed.

The evolution of the wall with towers was simple. The main requirements were despotism of power and unlimited labour. Thus the first examples of the system known to history are also amongst the earliest. One of these was Nineveh, built more than 2000 years B.C. The object of its huge perimeter, more than 50 m., has been mentioned. The wall was 120 ft. high and 30 ft. thick; and there were 1500 towers.

After this no practical advance in the art of fortification was made for a very long time, from a constructional point of view. Many centuries indeed elapsed before the inventive genius of man evolved engines and methods of attack fit to cope with such colossal obstacles.

The earliest form of attack was of course escalade, either by ladders or by heaping up a ramp of faggots or other portable materials. When the increasing height of walls made escalade too difficult, other means of attack had to be invented. Probably the first of these were the ram, for battering down the walls, and mining. The latter might have two objects: (a) to drive an underground gallery below the wall from the besiegers' position into the fortress, or (b) to destroy the wall itself by undermining.

The use of missile engines for throwing heavy projectiles probably came later. They are mentioned in the preparations made for the defence of Jerusalem against the Philistines in the 8th century B.C. They are not mentioned in connexion with the siege of Troy. At the sieges of Tyre and Jerusalem by Nebuchadrezzar in 587 B.C. we first find mention of the ram and of movable towers placed on mounds to overlook the walls.

The Asiatics, however, had not the qualities of mind necessary for a systematic development of siegecraft, and it was left for the Greeks practically to create this science. Taking it up in the 5th century B.C. they soon, under Philip of Macedon and Alexander, arrived at a very high degree of skill. They invented and systematized methods which were afterwards perfected by the Romans. Alexander's siegecraft was extremely practical. His successors endeavoured to improve on it by increasing the size of their missile and other engines, which, however, were so cumbersome that they were of little use. When the Romans a little later took up the science they returned to the practical methods of Alexander, and by the time of Caesar's wars had become past-masters of it. The
highest development of siegework before the use of gunpowder was probably attained in the early days of the Roman empire. The beginning of the Christian era is therefore a suitable period at which to take a survey of the arts of fortification and siegework as practised by the ancients.

In fortification the wall with towers was still the leading idea. The towers were preferred circular in plan, as this form offered the strongest possible resistance to a blow. The parapet of the wall was often covers by earth. When it was directly threatened by siege, it was protected by a ditch, which had three advantages: it increased the height of the obstacle, made the bringing up of the engines of attack more difficult, and supplied a place for the filling of the wall. In special cases, as at Jerusalem and Rhodes, the enclose walls were doubled and trebled. Citadel was also built on a large scale.

For a fortified town was on high ground sloping to a river on one side and with steep slopes falling away on the other three sides. At the highest point of a castle serving as citadel. The town enclosure was designed in accordance with the height of the surrounding country. Where the enemy’s approach was easiest, the walls were higher, flanking towers stronger and ditches wider and deeper. Some of the towers were made high for look-out purposes. For siege, however, the use of a bridge over the river, or was defended by a bridge-head on the far side; and stockades defended by towers were built out from either bank above and below the bridge, between which chains or beams could be stretched to prevent the enemy from crossing.

The natural features of the ground were skilfully utilized. Thus when a large town was spread over an irregular site broken by hills, the enceinte wall would be carried over the top of the hills; and in the valley between, the tower of the wall would not only be stronger, but would be somewhat drawn back to allow of a flanking defence from the hill tops on either side. The walls would consist of two strong masonry faces, 20 ft. apart, with a space between for earth and stones. When, however, the lie of the ground was favourable, the outside of the wall would be much higher than the inside, the parapet wall perhaps being a little above the level of the town. Palisades were used to strengthen the ditches, especially before the gates.

There was little scope, however, in machinery for the genius of Roman warfare, which had a better opportunity in the age of siegework. The Romano-Celtic machines were essentially aat way of siegework.

The object of mining, as has been said, might be the driving of a great breach, 23 large in diameter or the undermining of the wall. The latter was effected by excavating large chambers under the foundations. These were supported while the excavation was proceeding by timber struts and planking. When the chambers were ready, the timber struts were removed and the wall collapsed. The besieged replied to the mining attack by counter-mines. With these they would undermine and destroy the besiegers’ galleries, drawing in the mudmen and driving out the workers, either by force of arms or by filling the galleries with smoke.

Breaches in the wall were made by rams. These were of two kinds. For dislodging the cemented masonry of the face of the wall, sledge-pointed heads were used; when this was done, another head, shaped like a ram’s head, was substituted for battering down the filling of the wall.

For escalade they used ladders fixed on wheeled platforms; but the force of the various forms of attack against a high wall were the movable towers of wood. These were built so high that from their tops the parapet walk of the wall could be swept with arrows and stones; and drawbridges were let down from them, by which a storming party could reach the top of the wall. The height of the tower was from 70 to 150 ft. They were moved on wheels of solid oak or elm, 6 to 12 ft. in diameter and 3 to 4 ft. thick. The greatest height reached by such towers was 100 ft. While there might be as many as fifteen, were furnished with missile engines of a smaller kind. The archers occupied the top floor. There also were placed reserve towers. The so-called ‘ladder’ was of wood, and sometimes three or four vessels of this kind were used in series. The towers were also used as look-outs.

The defence. They were protected against fire by screens of osiers, plaited rope or raw hides. Sometimes it was necessary, in order to prevent further height from on high, to place a tower on a coast. In that case they would be built on the site. At the siege of Marseilles, described by Caesar, special methods of attack had to be employed on account of the strength of the engines used by the besiegers. The great mortar was 30 ft. long and 5 ft. thick, was built in front of one of the towers of the town to resist sorties. This fort was subse-trenches, each of six stories, under a roof which was projected beyond the walls, and from the coves of which hung heavy mats made of ships’ cables. The mats protected the men working at the walls, and as these were built up the roof was gradually raised. This would be made of heavy beams and planks, over which were laid bricks and clay, and the whole was covered with mats and hides to prevent the bricks from being dislodged. This structure was completed within the fort.

The great ram, which was a tower on wheels, or ram might be used as a shelter for miners or for workmen cutting away the face of the wall. The great ram at Marseilles, which extended from the tower already described to the wall, was 60 ft. long, weighed 1000 tons, and was fitted with great beams 2 ft. square, connected by iron pins and bands. It was unusually narrow, the ground slabs of the side walls being only 4 ft. apart. This was no doubt in order to keep down the weight of the machine in front of the wall, when the sloping roof and sides of timber were protected, like those of the tower, with bricks and moist clay, hides and twin mallets. Huge stone rollers or ‘crowling’ pits were wheeled from the wall upon this ram without effect, and under its cover the soldiers loosened and removed the foundations of the tower until it fell down. In order that it might be possible to move these heavy structures, it required the joint exertion of a hundred, or even two hundred, men with a horse under cover of which the earth brought up for filling the ditch was distributed.

The missile engines threw stones up to 600 lb. weight, heavy darts from 6 to 12 ft. long, and Greek fire. Archimedes at the siege of Syracuse even made some throwing 1000 lb. The ranges varied, according to the machine and the weight thrown, up to 600 yds. for direct fire and 1000 yds. for curved fire. At the siege of Jeru-salem, engines were employed which could reach 150 yds. and forty baliste, of which the smallest threw missiles of 75 lb. weight. At Carthage Scipio found 120 large and 281 medium catapults, 120 small catapults, and a great number of scorpions and other small missile engines.

Scree and mantlets for the protection of the engine-workers were used in great variety.

The addition to these great mechanical skill was shown in the construction of many kinds of machines for occasional purposes. A kind of fqn which was of great height on a movable platform was used to hoist a cage containing them on twenty men on to the walls. A long spar with a steel claw at the end, swung in the middle from a lofty frame, served to pull down the upper parts of parapets and undermining galleries. The defenders on their side were not slow in replying with similar devices. Feders were let down from the wall to soften the blow of the ram, or the head was raised and held by cranes. Grapnels were lowered from cranes to seize the rats and overturn them. Archimedes used the same idea in the case of the tower of Jerusalem, which he defended. Wooden towers were built on the walls to overtop the towers of the besiegers. Many devices for throwing fire were employed. The tradition that Archimedes burnt the Roman fleet, or a portion of it, at Syracuse, by focusing the rays of the sun with reflectors, is supported by an experiment made by Buffon in 1747. With a reflector having a surface of 50 sq. ft., made up of 168 small mirrors placed in parallel and arranged in the form of a parabola, a long spar was set on fire at 160 ft.

The development of masonry in permanent fortification had long since reached its practical limit, and was no longer progr against it. The siege machines were made of wood and the corresponded defences were, as is always the case, worn down by a relentless besieger, and the attack was stronger than the defence.

Through the dark ages the Eastern Empire kept alive the twin sciences of fortification and siegework long enough for the Crusaders to learn from them what had been lost in the West.
Byzantium, however, always a storehouse of military science, while conserving a knowledge of the ancient methods and the great missile engines, contributed no new ideas to fortification, so far as we know. In practice the Byzantines favoured multiplied encientes or several concentric lines of defence. This of course is always a tendency of decadent nations.

In the West the Roman fortifications remained standing, and the Visigoths, allies of Rome, utilized their principles in the defences of Carcassonne, Toulouse, &c. in the 5th century. Viollet-le-Duc's description and illustrations of the defences of Carcassonne will give a very good idea of the methods then in use:

"The Visigoth fortification of the city of Carcassonne, which is still preserved, offers an analogous arrangement recalling those described by Vegetius. The level of the town is much more elevated than the ground outside, and almost as high as the parapet walks. The curtain walls, of great thickness, are composed of two faces of small cubical masonry alternating with courses of brick; the middle portion being filled, not with earth but with rubble run with lime. The towers were raised above these curtains, and their communication with the latter might be cut off, so as to make of each tower a small independent fort; externally these towers are cylindrical, and on the side of the town square; they rest, also towards the country, upon a cubical base or foundation. We subjoin (fig. 1) the plan of one of these towers with the curtains adjoining. A is the plan of the ground-level; B the plan of the first storey at the level of the parapet. We see, at C and D, the two excavations formed in front of the gates of the tower to intercept, when the drawbridges were raised, all communication between the town or the parapet walk and the several storeys of the tower. From the first storey access was had to the upper crenellated or battlemented portion of the tower by a ladder of wood placed interiorly against the side of the flat wall. The external ground-level was much lower than that of the tower, and also beneath the ground-level of the town, from which it was reached by a descending flight of from ten to fifteen steps. Fig. 2 shows the tower and its two curtains on the side of the town; the bridges of communication are supposed to have been removed. The battlemented portion at the top is covered with a roof, and open on the side of the town in order to permit the defenders of the tower to see what was going on therein, and also to allow of their hoisting up stones and other projectiles by means of a rope and pulley. Fig. 3 shows the same tower on the side towards the country; we have added a postern, the sill of which is sufficiently raised above the ground to necessitate the use of a scaling or step ladder, to obtain ingress. The postern is defended, as was customary, by a palisade or barrier, each gate or postern being provided with a work of this kind."

Meanwhile, in western Europe, siegecraft had almost disappeared. Its perfect development was only possible for an army like that of the Romans. The Huns and Goths knew nothing of it, and the efforts of Charlemagne and others of the Frankish kings to restore the art were hampered by the fact that their warriors despised handicrafts and understood nothing but the use of their weapons. During the dark ages the towns of the Gauls retained their old Roman and Visigoth defences, which no one knew properly how to attack, and accordingly the sieges of that period dragged themselves out through long years, and if ultimately successful were so as a rule only through blockade and famine.

By this time a new departure of great importance had been made in the seigneurial castle (q.v.), which restored for some centuries a definite superiority to the defence. Built primarily as strongholds for local magnates or for small bodies of warriors dominating a conquered country, the conditions which called them into existence offered several marked advantages. The defences of a town had to follow the growth of the town, and would naturally have weak points. It was not to be expected that a town would develop itself in the manner most suitable for defence; nor indeed that any position large enough for a town could be found that would be naturally strong all round. But the site of a castle could be chosen purely for its natural strength, without regard, except as a secondary consideration, to the protection of anything outside it; and as its area was small it was often easy to find a natural position entirely suited for the purpose. In fact it frequently happened that the existence of such a position was the raison d'être of the castle. A small hill with steep sides might well be unapproachable in every direction by such cumbersome structures as towers and rats, while the height of the hill, added to the height of the walls, would be too much for the besiegers' missiles. If the sides of the hill were precipitous and rocky, mining became impossible, and the site was perfect for defence. A castle built under such conditions was practically impregnable; and this was the cause of the independence of the barons in the 11th and 12th centuries. They could only be reduced by blockade, and a blockade of long duration was very difficult in the feudal age.

A very instructive example of 12th-century work is the Château Gaillard, built by Richard Cœur-de-Lion in 1196. This great castle, with ditches and escarpments cut out of the solid rock, and extensive outworks, was completed in one year.

In the article Castle will be found the plan of the main work, which is here supplemented by an elevation of the donjon (or keep). The waved face of the inner or main wall of the castle, giving a divergent fire over the front, is an interesting feature in advance of the time. So also is the masonry protection of the machicolation at the top of the donjon, a protection which at that time was usually given by wooden boardings. After the death of Richard, Philip Augustus besieged the château, and carried it after a blockade of seven months and a regular attack of one month. In this attack the tower at A was first mined, after which the whole of that outwork was abandoned by the defenders. The outer enceinte was next captured by surprise; and finally the gate of the main wall was breached by the pioneers. When this happened a sudden rush of the besiegers...
prevented the remains of the garrison from gaining the shelter of the donjon, and they had to lay down their arms.

Château Gaillard, designed by perhaps the greatest general of his time, exemplifies in its brief resistance the weak points of the designs of the 12th century. It is easy to understand how at each step gained by the besiegers the very difficulties which had been placed in the way of their further advance prevented the garrison from reinforcing strongly the points attacked.

In the 13th century many influences were at work in the development of castellar fortification. The experience of such sieges as that of Château Gaillard, and still more that gained in the Crusades, the larger garrisons at the disposal of the great feudal lords, and the importance of the interests which they had to protect in their towns, led to a freer style of design. We must also take note of an essential difference between the forms of attack preferred by the Roman soldier and by the medieval chivalry. The former, who were artisans as well as soldiers, preferred in siege works the certain if laborious methods of breaching and mining. The latter, who considered all manual labour beneath them and whose only ideal of warfare was personal combat, affected the tower and bridge, giving access to the top of the wall rather than the rat and battering-ram. They were also fond of surprises, which the bad discipline of the time favoured.

We find, therefore, important progress in enlarging the area of defence and in improving arrangements for flanking. The size and height of all works were increased. The keep of Coucy Castle, built in 1220, was 200 ft. high. Montargis Castle, also built about this time, had a central donjon and a large open enclosure, within which hedges were planted to give access to the top of the wall rather than the rat and battering-ram. They were also fond of surprises, which the bad discipline of the time favoured.

We find also a tendency, the influence of which lasted long after medieval times, towards complexity and multiplication of defences, to guard against surprise and localize successful assaults. Great attention was paid to the step by step defence. Flanking towers were cut off from their walls and arranged for separate resistance. Complicated entrances with traps and many doors were arranged. Almost all defences were on the tops of the walls and towers, the loopholes on the lower storeys being mainly for light and air and reconnoitring. Machicoulis galleries (for vertical defence) were protected either by stone walls built out on corbels, or by strong timber hoardings built in war time, for which the walls were prepared beforehand by recesses left in the masonry. Loopholes and crenelles were protected by shutters. Great care and much ingenuity were expended on details of all kinds.

Already in the 12th century the engineers of the defence had made provision for countermarching, by building chambers and galleries at the base of the towers and walls. Further protection for the towers against the pioneer attack was given by carrying out the masonry in front of the tower in a kind of projecting horn. This was found later to have the further advantages of doing away with the dead ground in front of the tower unseen from the curtain, and of increasing the projection and therefore the flanking power of the tower itself. The arrangement is seen in several of the towers at Carcassonne, and has in it the germ of the idea of the bastion.

The defences of Carcassonne, remodelled in the latter half of the 13th century on the old Visigothic foundations, exemplify some of the best work of the period. Figs. 5 and 6 (reproduced from Viollet-le-Duc) show the plan of the defences of the town and castle, and a bird's-eye view of the castle with its two barbicans. The thick black line shows the main wall; beyond this are the lists and then the moat. It will be noted that the wall of the lists as well as the main wall is defended by towers. There are only two gates. That on the east is defended by two great towers and a semicircular barbican. The gate of the castle, on the west, has a most complicated approach defended by a labyrinth of gates and flanking outside, which cannot be shown on this small scale, and beyond these is a large circular barbican in several storeys, capable of holding 1500 men. On the side of the town the castle is protected by a wide moat, and the entrance is masked by another large semicircular barbican. An interesting feature of the general arrangement is the importance which the lists have assumed. The slight wooden barricade of earlier times has developed into a wall with towers; and the effect is that the besieger, if he gains a footing in the lists, has a very narrow space in which to work the engines of attack. The castle, after the Roman fashion, adjoins the outer wall of the town, so that there may be a possibility of communicating with a relieving force from the inside.

The siegecraft of the period was still that of the ancients. Mining was the most effective form of attack, and the approach to the walls was covered by engines throwing great stones against the hoardings of the parapets, and by cross-bowmen who were stationed behind light mantlets moved on wheels. Barrels of burning pitch and other incendiary projectiles were thrown before; and at one siege we read of the carcasses of dead horses and barrels of sewage being thrown into the town to breed pestilence, which had the effect of forcing a capitulation.

With all this the attack was inferior to the defence. As Professor C. W. C. Oman has pointed out, the mechanical application of the three powers of tension, torsion and counterpoise (in the missile engines) had its limits. If these engines were enlarged they grew too costly and unwieldy. If they were multiplied it was impossible on account of their short range and great bulk to concentrate the fire of enough of them on a single portion of the wall.

It is difficult to give anything like an accurate account, in a small space, of the changes in fortification which took place in the first two centuries after the introduction of gunpowder. The number of existing fortifications that had to be modified was infinite, so also was the number of attempted solutions of the new problems. Engineers did not yet begin to publish descriptions of their "systems"; also the new names and terms which came into use with the new works were spread over Europe by engineers of different countries, and adopted into new languages without much accuracy.

Artillery was in use for some time before it began to have any effect on the design of fortification. The earliest cannon threw so very light a projectile that they had no effect on masonry and
were more useful for the defence than the attack. Later, larger pieces were made, which acted practically as mortars, throwing stone balls with high elevation, and barrels of burning composition. In the middle of the 15th century the art of cannon-founding was much developed by the brothers Bureau in France. They introduced iron cannon balls and greatly strengthened the guns. In 1428 the English besieging Orleans were entirely defeated by the superior artillery of the besieged. By 1450 Charles VII. was furnished with so powerful a siege train that he captured the whole of the castles in Normandy from the English in one year.

But the great change came after the invasion of Italy by Charles VIII. with a greatly improved siege train in 1494. The astonishing rapidity with which castles and fortified towns fell before him proved the uselessness of the old defences. It became necessary to create a new system of defences, and, says Casseron de Villiers, "thanks to the mental activity of the Renaissance and the warlike conditions prevailing everywhere, the time could not have been more favourable." There is no doubt that the engineers of Italy as a body were responsible for the first advance in fortification. There, where vital and mental energy were at a boiling point, and where the first striking demonstration of the new force had been given, the greatest intellects, men such as Leonardo da Vinci, Michelangelo and Machiavelli, busied themselves over the problem of defence.

It has been claimed that Albert Dürer was the first writer on modern fortification. This was not so; Dürer’s work was published in 1527, and more than one Italian engineer, certainly Martini of Siena and San Gallo, had preceded him. Also Machia-velli, writing between 1512 and 1527, had offered some most valuable criticisms and general principles. Dürer, moreover, had little influence on the progress of fortification; though we may see in his ideas, if we choose, the germ of the "polygonal" system, developed long afterwards by Montalembert. Dürer’s work was to some extent a connecting link between the old fortification and the new. He proposed greatly to enlarge the old towers; and he provided both them and the curtains with vaulted chambers for guns (casemates) in several tiers, so as to command both the ditch and the ground beyond it. His projects were too massive and costly for execution, but his name is associated with the first practical gun casemates.

Before beginning to trace the effect of gunpowder on the design of fortification, it may be noted that two causes weakened the influence of the castles. First, their owners were slow to adopt the new ideas and abandon their high strong walls for low extended parapets, and, secondly, they had not the men necessary for long lines of defence. At the same time the corporations of the towns had learnt to take an active part in warfare, and provided trained and disciplined soldiers in large numbers.

When artillery became strong enough to destroy masonry from a distance two results followed: it was necessary to modify the masonry defences so as to make them less vulnerable, and to improve the means of employing the guns of the defence. For both these purposes the older castles with their restricted area were little suited, and we must now trace the development of the fortified towns.

Probably the first form of construction directly due to the appearance of the new weapons was the bulwark (bourreau, buluardo or bollwerk). This was an outwork usually semicircular in plan, built of earth consolidated with timber and revetted with hurdles. Such works were placed as a shield in front of the gates, which could be destroyed even by the early light cannon-balls; and they offered at the same time advanced positions for the guns of the defence. They were found so useful for gun positions for flanking fire that later they were placed in front of towers or at intervals along the walls for that purpose.

This, however, was only a temporary expedient, and we have now to consider the radical modifications in designs. These affected both the construction and trace of the walls.

The first lesson taught by improved artillery was that the walls should not be set up on high as targets, but in some manner screened. One method of doing this in the case of old works was by placing bulwarks in front of them. In other cases the inner walls, being protected by the moats, were already partially screened and suitable for conversion into the main defence; and as with improved flanking defence great height was no longer essential, the tops of the walls were in some cases cut down. In new works it was natural to sink the wall in a ditch, the earth from which was useful for making rAMPARTs.

As regards resistance to the effect of shot, it was found that thin masonry walls with rubble filling behind them were very easily destroyed. A bank of earth behind the wall lessened the vibration of the shot, but once a breach was made the earth came down, making a slope convenient for ascent. To obviate this, horizontal layers of brickwork and timber and sometimes masonry were built into the earth bank, and answered very well (fig. 7).

Another expedient of still greater value was the use of counterforts. The earliest counterforts were simply buttresses built inward from the wall into the rampart instead of outward. Their effect was to strengthen the wall and make the breaches more difficult of ascent. An alternative arrangement for strengthening the wall was an arched gallery built behind it under the rampart (fig. 9). This construction was in harmony with the idea, already familiar, of a passage in the wall from which countermines could be started; but it has the obvious weakness that the destruction of the face wall takes away one of the supports of the arch. The best arrangement, which is ascribed to Albert Dürer, was the "counter-arched revetment." This consisted of a series of arches built between the counterforts, with their axes at right angles to the face of the wall. Their advantage was that, while supporting the wall and taking all the weight of the rampart, they formed an obstacle after the destruction of the wall more difficult to surmount than the wall itself and very hard to destroy. The counter-arches might be in one, two or three tiers, according to the height of the wall (figs. 10 and 11, the latter without the earth of the rampart and showing also a countermining gallery).

A more important question, however, than the improvement of the passive defence or obstacle was the development of the active
FORTIFICATION AND SIEGECRAFT

defence by artillery. For this purpose it was necessary to find room for the working of the guns. At the outset it was of course a question of modifying the existing defences at as little cost as possible. With this object the roofs of towers were removed and platforms for guns substituted, but this only gave room for one or two guns. Also the loopholes in the lower storeys of towers were converted into embrasures to give a grazing fire over the ditch; this became the commonest method of strengthening old works for cannon, but was of little use as the resulting field of fire was so small. In some cases the towers were made larger, with a semi-circular front and side walls at right angles to the curtain. Such towers built at Langres early in the 16th century had walls 20 ft. thick to resist battering.

Even in new works some attempts were made to combine artillery defence with pure masonry protection. The works of Albert Dürer in theory, and the bridge-head of Schaaffhausen in practice, are the best examples of this. The Italian engineers also showed much ingenuity in arranging for the defence of ditches with masonry caponiers. These were developed from external buttresses, and equally with the casemated flanking towers of Dürer contained the germ of the idea of "polygonal" defence.

The ditch. The ditch, which had only been occasionally used in ancient and medieval fortification, now became essential and characteristic. Serving as it did for the double purpose of supplying earth for a rampart and allowing the wall to be sunk for concealment, it was found also to have a definite use as an obstacle. Hitherto the wall had sufficed for this purpose, the ditch being useful mainly to prevent the besieger from bringing up heavy engines of attack.

The natural solution, however, which was soon generally adopted, was the rampart; that is, a bank of earth thrown up behind the wall, which, while strengthening the wall as already indicated, offered plenty of space for the disposal of the guns.

The cutting of earth for a rampart and allowing the wall to be sunk for concealment, it was found also to have a definite use as an obstacle. Hitherto the wall had sufficed for this purpose, the ditch being useful mainly to prevent the besieger from bringing up heavy engines of attack.

When the wall (or escarp) was lowered, the obstacle in the wall which the ditch was increased by retreating the far side of it with a counterscarp. Beyond the counterscarp wall some of the earth excavated from the ditch was piled up to increase the protection given to the escarp with its defenses so that the earth was dropped down gently on the outer side to meet the natural surface of the ground in such a manner as to be swept by the fire from the ramparts and was called the glacis.

Now, however, a new difficulty arose. In all times a chief element in a successful defence has consisted in action by the besieged outside the walls. The old ditches, when they existed, had merely a slope on the far side leading up to the ground-level; and the ditch was a convenient place in which troops preparing for a sortie could assemble without being seen by the enemy, and ascend the slope to make their attack. The introduction of the counterscarp wall prevented sortie from the ditch. At first it was customary, after the introduction of the counterscarp, to leave a narrow space on the top of it, behind the glacis, for a patrol path. Eventually the difficulty was met by widening this patrol path into a space of about 50 ft., in which there was room for troops to assemble. This was known as the covered way.

With this last addition the ordinary elements of a profile of modern fortification were complete and are exemplified in fig. 12.

Up to the gunpowder period the trace of fortifications, that is, the plan on which they were arranged on the ground, was very simple. It was merely a question of an enclosure wall adapted to the site and provided with towers at suitable intervals. The foot of the wall could be seen and defended everywhere, from the tops of the towers and the machicolated galleries. The introduction of ramparts and artillery made this more difficult in two ways. The rampart, interposed between the defenders and the face of the wall, put a stop to vertical defence. Also with the inferior gun-carriages of the time very little depression could be given to the guns, and thus the top of the enceinte wall, with or without a rampart, was not a suitable position for guns intended to flank the ditch in their immediate neighbourhood. The problem of the "trace" therefore at the beginning of the 17th century was to rearrange the line of defence so as to give due opportunity to the artillery of the besieged, both to oppose the besiegers' breaching batteries and later to defend the breaches. At the outset the latter role was the more important.

In considering the early efforts of engineers to solve this problem we must remember that for economical reasons they had to make the best use they could of the existing walls. At first for flanking purposes casemates on the ditch level were used, the old flanking towers being enlarged for the purpose. Masonry galleries were constructed across the ditch, containing casemates which could fire to either side, and after this casemates were placed in the counterscarp. Some use was also made of the fire from detached bulwarks. It was soon realized, however, that the flanking defence of the body of the place ought not to be dependent on outworks, and that greater freedom was required for guns than was consistent with casemate defence. The bulwark (which in its earliest shape suggests that it was in some sort the offspring of the barbican, placed to protect an entrance) gave plenty of space for guns, but was too detached for security. The enlarged tower, as an integral part of the lines, gave security, and its walls at right angles to the curtain gave direct flanking fire, but the guns in it were too cramped. The blending of the two ideas produced the bastion, an element of fortification which dominated the science for three hundred years, and so impressed itself on the imagination that to this day any strong advanced position in a defensive line is called by that name by unscientific writers. The word had been in use for a long time in connexion with extemporized towers or platforms for flanking purposes, the earliest forms being bastille, bastide, bastillon, and in its origin it apparently refers rather to the quality of work in the construction than to its defensive intention.

The earliest bastions were modified bulwarks with straight faces and flanks, attached to the main wall, for which the old towers often acted as keeps; and at first the terms bulwark and bastion were more or less interchangeable. Fig. 13, taken from a contemporary MS. by Viollet-le-Duc, shows a bastion added to the old wall of Troyes about 1528. On the other hand, in fig. 14 (taken from an English MS. of 1559, which again is based on the Italian work of Zanchi published in 1554), we find a a a a spoken of as "bassils," and b b b as "bastions." The triangular works between the bastions are described as "ramparts," intended to protect the curtains from breaching fire. (We may also notice in this work the broad ditch, the counterscarp with narrow covered way, and loopholes indicating counterscarp galleries.)

Towards the end of the 17th century the term "bulwark" began to be reserved for banks of earth thrown up a little distance in front of the main wall to protect it from breaching fire, and it thus reverted to its original defensive intention. The term "bastion" henceforth denoted an artillery position connected by flanks to the main wall; and the question of the arrangement of these flanks was one of the main preoccupations of engineers.
Flanks retired, casemated or open, or sometimes in several tiers were proposed in infinite variety.

**Fig. 14.**

Thus, while in the early part of the 16th century the actual modification of existing defences was proceeding very slowly on account of the expense involved, the era of theoretical "systems" had begun, based on the mutual relations of flank and face. These can be grouped under three heads as follows:

1. The *embrasure* or indented trace: Faces and flanks succeeding each other in regular order (fig. 15).

2. The *tenaille* trace: Flanks back to back between the faces (fig. 16). The development of the flanks in this case gives us the star trace (fig. 17).

3. The *bastioned* trace: Flanks facing each other and connected by curtains (fig. 18).

In comparing these three traces it will be observed that unless casemates are used the flanking in the first two is incomplete. Gaps on the ramparts of the faces cannot defend the flanks, and therefore there are "dead" angles in the ditch. In the bastioned trace there is no "dead" ground, provided the flanks are so far apart that a shot from the rampart of a flank can reach the ditch at the centre of the curtain.

Here was the parting of the ways. For those who objected to casemate fire, the bastioned trace was the way of salvation. They were soon in the majority; perhaps because the symmetry and completeness of the idea captivated the imagination. At all events the bastioned trace, once fairly developed, held the field in one form or another practically without a rival until near the end of the 17th century. The Italian engineers, who were supreme throughout most of the 16th century, started it; the French, who took the lead in the following century, developed it, and officially never deserted it until late in the 19th century, when the increasing power of artillery made enceintes of secondary importance.

It will be useful at this point to go forward a little, with a couple of explanatory figures, in order to get a grasp of the component parts of the bastioned trace as ultimately developed, and of its outworks.

**Fig. 19.**

In fig. 19 ABCD represents part of an imaginary line drawn round the place to be fortified, forming a polygon, regular or irregular. ABC is an *exterior angle* or angle of the polygon.

BC is an *exterior side*. 

xy is a *perpendicular*, the proportionate length of which to the exterior side BC (usually about one-sixth) is an important element of the trace.

Two demi-bastions with the connecting curtain make the bastioned front, defgh.

The *tenaille* is the trace of the enceinte.

aefghi is the trace of the enceinte.

bdef is a bastion.

de is a base trace.

def is a face of the bastion.

e is a flank of the bastion.

fl is the curtain. 

bj is the gorge.

*Fig. 20.*

Different kinds of outworks then in use. The following is the explanation of its figuring and lettering.

1. *Flat bastion*: Placed in the middle of a curtain when the lines of defence were too long for musketry range.

3. *Tenaille bastion*: Used when the flanked angle is too acute; that is, less than 70°.

4. *Redans*: Used along the bank of a river, or when the parapet of the covered way can be taken in reverse from the front.

A, B, Ravelins.

C, *Demi-Lunes*: So called from the shape of the gorge. They differ from the ravelins in being placed in front of the bastions instead of the curtains.

D, *Counter-guards*: Used instead of demi-lunes, which were then going out of fashion.

E, *Simple tenaille*.

F, *Double tenaille* (see L and M).

(The tenaille E is placed in width towards the gorge, as shown alternatively, it is called a swallow-tail. If the double tenaille is

&. Traverses to protect the terreplein of the ramparts from enfilade.

Turning back now to the middle of the 16th century we find in the early examples of the use of the bastion that there is no attempt made to defend its faces by flanking fire, the curtains being considered the only weak points of the enceinte. Accordingly, the flanks are arranged at right angles to the curtain, and the prolongation of the faces sometimes falls near the middle of it. When it was found that the faces needed protection, the first attempts to give it were made by erecting cavaliers, or raised parapets, behind the parapet of the curtain or in the bastions.

The first example of the complete bastioned system is found in Paciotto’s citadel of Antwerp, built in 1568 (fig. 21). Here we have faces, flanks and curtain in due proportion; the faces long enough to contain a powerful battery, and the flanks able to defend both curtain and faces. The weak points of this trace, due to its being arranged on a small pentagon, are that the terreplein or interior space of the bastions is rather cramped, and the salient angles too acute.

In the systems published by Speckle of Strassburg in 1589 we find a distinct advance. Speckle’s actual constructions in fortification are of no great importance; but he was a great traveller and observer, and in his work, published just before his death, he has evidently assimilated, and to some extent improved, the best ideas that had been put forward up to that time.

Two specimens from Speckle’s work are well worth studying as connecting links between the 16th and 17th centuries.

Fig. 22 is early 16th-century work much improved. There are no outworks, except the covered way, now fully developed, with a battery in the re-entering place of arms. The bastions are large, but the faces directed on the curtain get little protection from the flanks. To make up for this they are flanked by the large cavaliers in the middle of the curtain. The careful arrangement of the flank should be noted; part of it is retired, with two tiers of fire, some of which is arranged to bear on the face of the bastion. The great saliency of the bastion is a weak point, but the whole arrangement is simple and strong.

In the second example, known as Speckle’s “reinforced trace” (fig. 23), we find him anticipating the work of the next century. The ravelin is here introduced, and made so large that its faces are in prolongation of those of the bastions. Speckle’s other favourite ideas are here: the cavaliers and double parapets and his own particular invention of the low batteries behind the re-entering place of arms and the gorge of the ravelin. These low batteries did not find favour with other writers, being liable to be too easily destroyed by the besiegers’ batteries crowning the salients of the covered way.

Speckle’s book is of great importance as embodying the best work of the period. His own ideas are large and simple, but rather in advance of the powers of the artillery of his day.

At the beginning of the 17th century we find the Italian engineers following Paciotto in developing the complete bastioned trace; but they got on to a bad line of thought in trying to reduce everything to symmetry and system. The era of geometrical fortification (or, as Sir George Clarke has called it, “drawing-board” fortification) had already begun with Marchi, and his followers busied themselves entirely in finding geometrical solutions for the application of symmetrical bastioned fronts to such imaginary forms of perimeter as the oval, club, heart, figure of eight, &c. Marchi, however, was one of the first to think of prolonging the resistance of a place by means of outworks such as the ravelin. De Villenoisy says that Busca was the first to discuss the proportions and functions of all the component parts of a front; and Floriani, about 1630, was the last of the important Italians. The characteristics of a good deal of Spanish fortification carried out at this time were, according to the same authority, that the works were well adapted to sites, and the masonry excellent but too much exposed, while the bastions were too small. The Dutch and German schools will be referred to later.

The French engineers now began to take the lead in adapting the principles already established to actual sites. In the first half of the century the names of de Ville and Pagan stand out as having contributed valuable studies to the advancement of the science. In putting forward their designs they discussed very fully such practical questions as the length of the line of defence, whether this should be governed by the range of artillery or musketry fire, the length of flanks, the use in them of orillons, casemates and retired flanks, the size of bastions, &c.

It is the latter half of the 17th century, however, which is one
of the most important periods in the history of fortification, chiefly because it was illuminated by the work of Vauban. It was at this time also that a prodigious output of purely theoretical fortification began, which went on till the French Revolution. Many of the "systems" published at this time were elaborated by men who had no practical knowledge of the subject, some of them priests who were engaged in educating the sons of the upper classes, and who had to teach the elements of fortification among other things. They naturally wrote treatises, which were valuable for their clearness of style; and with their industry and ingenuity the elaboration of existing methods was a very congenial task. Most of these essays took the form of multiplication and elaboration of outworks on an impossible scale, and they culminated in such fantastic extravagances as the system of Rhana, published in 1769 (fig. 24). These proposals, however, were of no practical importance.

The works of the real masters who knew more than they published can always be recognized by its comparative simplicity. The greatest of these was Sebastien le Prestre de Vauban (q.v.). Born in 1633, and busied from his eighteenth year till his death in 1707 in war or preparations for war, he earned alike by his genius, his experience, his industry and his personal character the chief place among modern military engineers. His experience alone puts him in a category apart from others. Of this it is enough to say that he took part in forty-eight sieges, forty of which he directed as chief engineer without a single failure, and repaired or constructed more than 160 places. Vauban's genius was essentially practical, and he was no believer in systems. He would say, "One does not fortify by systems but by common sense." Of new ideas in fortification he introduced practically none, but he improved and modified existing ideas with consummate skill in actual construction. His most original work was in the attack (see below), which he reduced to a scientific method most certain in its results. It is therefore one of the ironies of fate that Vauban should be chiefly known to us by three so-called "systems," known as his "first," "second" and "third." How far he was from following a system is shown by de Villenoisy, who reproduces twenty-eight fronts constructed by him between 1667 and 1668, no two of which are quite alike and most of which vary very considerably to suit local conditions.

Vauban's "first system," as variously described by other writers even in his own time, is pieced together from some of the early examples of his work. The "second system" is the "tower bastion" defence of Bel- fort and Landau (1684-1688), obviously suggested by a design of Castriotto's one hundred years earlier; and the "third system" is the front of Neu-Breisach (1688), which is merely Landau slightly improved. In other works, between 1688 and 1698, he did not keep to the tower bastion idea. It will be convenient to take the "first system," as reproduced in the Royal Military Academy text book of fortification (fig. 25) as typical of much of Vauban's work. It may be observed that he sometimes uses the straight flank, and sometimes the curved flank with orillon. Parapets in several tiers are never used, nor cavaliers. The ravelin is almost always used. It is small, having little artillery power and giving no protection to the shoulders of the bastions. Sometimes it has flanks and occasionally a keep.

The tenaille is very generally found. In this form, viz. as a shield to the escarp of the curtain, it was probably invented by him. Fig. 25 shows two forms. In both the parapet of the tenaille had to be kept low, so that the flanks might defend a breach at the shoulder of the opposite bastion, with artillerie fire striking within 12 ft. of the base of the escarp. Traverses are used for the first time on the covered way to guard against enfilade fire; and the re-entering place of arms, to which Vauban attached considerable importance, is large.

For the construction of the trace an average length of about 400 yds. (which, however, is a matter entirely dependent on the site) may be taken for the exterior side. The perpendicular, except for polygons of less than six sides, is one-sixth, and the faces of the bastions two-sevenths of the exterior side. The flanks are chords of arcs struck from the opposite shoulder as centres. An are described with the same radius, but with the angle of the flank as a centre, and cutting the perpendicular produced outwardly, gives the salient of the ravelin; the prolongations of the faces of the ravelin fall upon the faces of the bastions at 11 yds. from the shoulders. The main ditch has a width of 38 yds. at the salient of the bastions, and the counterscarp is directed upon the shoulders of the adjoining bastions.

The ditch of the ravelin is 24 yds. wide throughout. As regards the profile the bastions and curtain have a command of 25 ft. over the country, 17 ft. over the crest of the glacis and 8 ft. over the ravelin. The ditches are 18 ft. deep throughout. The parapets are 18 ft. thick with full revetments. In his later works he used demi-revetments.

Fig. 26 shows the tower bastions of Neu-Breisach, or the so-called "third system." It is worth introducing, simply as showing that even a mind like Vauban's could not resist in old age the tendency to duplicate defences. Here the main bastions and tenaille are detached from the enceinte. The line of the enceinte is broken with flanks advanced and backed by the towers. The ravelin is large and has a keep. The section through the face of the bastion shows a demi-revetment with wide bern, and a hedge as an additional obstacle.

After Vauban died, though the theories continued, the valuable additions to the system were few. Among his successors in the early part of the 18th century Cormontaigne (q.v.) has the greatest reputation, though his experience and authority fell far short of Vauban's. He was a clear thinker and writer, and the elements of the system were distinctly advanced by him. His trace includes an enlarged ravelin with flanks, the ends of which were intended to close the gaps at the end of the tenaille, and a keep to the ravelin with flanks. He provides a very large re-entering place of arms, also with a keep, the ditches of which are carefully traced so as to be protected from enfilade by the salients of the ravelin and bastion. He was also in favour of a permanent retenchment of the gorge of the bastion. His works were printed, with many alterations, more than twenty years after his death, to serve as a text-book for the school of Mezières. This school was established in 1715, and from this time forward there was an official school of thought, based on Vauban. Cormontaigne's work, therefore, represents the modifications of Vauban's ideas accepted.
by French engineers in the latter part of the 18th century. The school of Mézières was afterwards replaced by that of Metz, which carried on its traditions. Such schools are necessarily conservative, and hence, in spite of the gradual improvement in ordnance and firearms, we find the main elements of the bastioned system remaining unchanged right up to the period of

FIG. 26.—Neu-Breisach.

the Franco-German War in 1870. Chasseloup-Laubat tells us that, before the Revolution, to attempt novelties in fortification was to write one's self down ignorant. How far the general form of the bastion with its outworks had become crystallized is evident from a cursory comparison of fig. 27 with Vauban's

FIG. 27.—Noizet.

early work. This figure is the front of the Metz school in 1822, by General Noizet.

Since, therefore, the official view was that the general outlines of the system were sacred, the efforts of orthodox engineers from Cormontaigne's time onwards were given to improvements of detail, and mainly to retard breaching operations as long as possible. We find enormous pains being bestowed on the study of the comparative heights of the masonry walls and crest levels; with the introduction here and there of glacis slopes in the ditches,

put in both to facilitate their defence and to protect portions of the escars.

Among the unorthodox two names deserve mention. The first of these is Chasseloup-Laubat (q.v.), who served throughout the wars of the Republic and Empire, and constructed the fortress of Alessandria in Piedmont.

Chasseloup's main proposals to improve the bastioned system were two:

First, in order to prevent the bastions from being breached through the gaps made by the ditch of the ravelin, he threw forward the ravelin and its keep outside the main glacis. This had the further advantage of giving great saliency to the ravelin for cross-fire over the terrain of the attack. On the other hand, it made the ravelin liable to capture by the gorge. It is probable that this system would have lent itself to a splendid defence by an able commander with a strong force; but under the opposite conditions it has a dangerous element of weakness.

Secondly, in order to get freedom to use longer fronts than those admissible for the ordinary bastioned trace, he proposed to extend his exterior side up to about 650 yds, and to break the faces of his bastions; the portion next the shoulder being defended from the flank of the collateral bastion and coinciding with the line of defence, and the portion next the salient, up to about 80 yds, in length, being defended from a central keep or caponier placed in front of the tenaille. The natural criticism of this arrangement is that it combines some of the defects of both the bastioned and polygonal systems without getting the full advantages of either.

Fig. 28 shows a half front of Chasseloup's system, of ordinary length, as actually constructed. The section shows an interesting

detail, viz. the Chasseloup mask—a detached mask with tunnels for the casemate guns to fire through, the intention of which is to save them from being destroyed from a distance.

The second name is that of Captain Choumara of the French Engineers, born in 1787, whose work was published in 1827.
Two leading ideas are due to him. The first is that of the "independence of parapets." A glance at any of the plans that have already been shown will show that hitherto the crests of parapets had always been traced parallel to the escarp or magistral line. Choumara pointed out that, while it was necessary for the escarp to be traced in straight lines with reference to the flanking arrangements, there was no such necessity as regards the parapets. By making the crest of the parapet quite independent of the escarp line he obtained great freedom of direction for his fire. The second idea is that of the "inner glacis." This was a glacis parapet placed in the main ditch to shield the escarp; its effect being to prevent the escarp of the body of the place from being breached in the usual way by batteries crowning the crest of the covered way.

The need for Choumara's improvements has passed by, but he was in his time a real teacher. One sentence of his strikes a resounding note: "What is chiefly required in fortification is simplicity and strength. It is not on a few little contrivances carefully hidden that one can rely for a good defence. The fate of a place should not depend on the intelligence of a corporal shut up in a small post prepared for his detachment."

Before leaving the bastioned system it will be of interest to study a couple of actual and complete examples, one irregular and one regular. Fig. 29 shows the defences of Sedan as they were at the end of the 17th century. One sees the touch of Vauban here and there, but the work is for the most part apparently early 17th century. It will be observed that on the river side of the town the defence consists of very irregular bastions with duplicated wet ditches (see the Dutch style, below); and on the other side, where water is not available, strength is sought for by pushing a succession of hornworks far out.

Fig. 30 is Saarlouis, constructed by Vauban in 1680 in his early manner, a remarkable example of symmetry. Vauban of course never thought of aiming at symmetry, which is of itself neither good nor bad, but it is interesting to note such a perfect example of the system.

It must here be remarked that the reproach of "geometrical" fortification is in no way applicable to the works of Vauban and his immediate successors. The true geometric fortification, which worshiped symmetry as a fetish, marked, as has been already pointed out, the decadence of the Italian school. Vauban and his fellows excelled in adapting works to sites, the real test of the engineer.

The bastioned system was the 17th-century solution of the fortification problem. Given an artillery and musketry of short range and too slow for effective frontal defence, a ditch is necessary as an obstacle. What is the best means of flanking the ditch and of protecting the flanking arrangements? If Vauban elected for the bastion, we must before criticizing his choice remember that he was the most experienced engineer of his day, a man of the first ability and quite without prejudice. What is matter for regret is that the authority of Vauban should have practically paralysed the French school during the 18th and most of the 19th century, so that while the conditions of attack and defence were gradually altering they could admit no change of idea, and their best men, who could not help being original, were struggling against the whole weight of official opposition.

Again, such duplication of outworks as we see at Sedan is not geometric fortification. It is a definite attempt to retard the attack, on ground favourable to it, by successive lines of defence. As to the policy of this, no axiom can be laid down. Nowadays most of us think, as Machiavelli did, that a single line of defence is best and that a second line only serves to suggest the advisability of retreat. There are also, of course, the recognized drawbacks of outworks, difficulty of retreat, of relief and so forth, and the moral effect of their loss. But the engineers of such defences as Ostend and Cadiz might well say, "Oh, if only when we had held on to that bastion for so many months we had had a second and a third line of permanent retribution to fall back upon, we could have held the place for ever." And who shall say that they were wrong? Let us at all events remember that the leading engineers of that time were men who had passed their lives in a state of war, and that we ourselves in comparison with them are the theorists.

From the end of the 16th century the Dutch methods of fortification acquired a great reputation, thanks to the stout resistance offered to the Spaniards by some of their fortresses, the three years' defence of Ostend being perhaps the most striking example. Prolonged defences, which were mainly due to the desperate energy of the besieged, were credited to the quality of their defences. In point of fact the Dutch owed more to nature, and more still to their own spirit, than to art; but they showed a good deal of skill in adapting recent ideas to their needs.

Three conditions governed the development of the Dutch works at this time, viz. want of time, want of money and abundance of water. When the Netherlands began their revolt against Spain, they would no doubt have been glad enough of expensive masonry fortresses on such models as Paciotto's citadel of Anvers. But there was neither time nor money for such works. Something had to be extemporized, and fortunately for them they had wet ditches to take the place of high revetted walls. Everywhere water was near the surface, and rivers or canals were available for inundations. A wide and shallow ditch, while making a good obstacle, was also the readiest means of obtaining earth for the ramparts. High command was, owing to the flatness of the country, unnecessary and even undesirable, as it did not allow of grazing fire.

What the Dutch actually did in strengthening their towns gives little evidence of system. Starting as a rule from an existing enceinte, sometimes a medieval wall, they would provide a broad wet ditch. No further provision was usually made on the sides of the town which were additionally protected by a river or inundation. On the other sides the wet ditch was made still broader, and sometimes contained a counterguard, sometimes ravelins and lunettes. These were quite irregular in their design and relation to each other. At the foot of the glacis would be found another but narrower wet ditch, which was a peculiarly Dutch feature; and sometimes if the town was in a bend of a river there would be a canal cut across the bend in a straight line, strengthened by several redans.

Speaking generally, they endeavoured to provide for the want Fig. 29.—Sedan in 1705.
of a first-class masonry obstacle by multiplication of wet ditches, and further to strengthen these obstacles by great quantities of palisading, for which purpose the timber of old ships was used. They also recognized the inherent weaknesses of wet ditches, as, for instance, that when frozen they no longer provide an obstacle; and they studied the means, not only of causing inundations, but also of arranging to empty as well as to fill the ditches at will. Simon Stevin was the leader in this work.

Nevertheless a Dutch school of design did come into existence at this time. The leaders, early in the 17th century, were Simon Stevin, Maurice and Henry of Nassau, Marolois and Freitag. The fortress of Coevorden, constructed by Prince Maurice, of which fig. 31 shows a front, is a well-known example of this, and the section shows clearly some typical features of the school.

The elements of the plan are those of the early bastioned trace, but we find added both ravelins and lunettes, very regular in design. There is also the ditch at the foot of the glacis, and surrounding the rampart of the enceinte a continuous fausse-braie. This work, which partook of the nature of both boulevard and counterguard, served several purposes. It was desirable that the weight of the rampart should be drawn back a little from the edge of the ditch, and the fausse-braie filled what would otherwise have been dead ground at the foot of the rampart. It also afforded a grazing fire over the ditch, which was very important, and which the rampart supported by a plunging fire.

Coehorn (q.v.), the contemporary and nearest rival to Vauban, was the greatest light of the Dutch school. Like Vauban he was distinguished as a fighting engineer, both in attack and defence; but in the attack he differed from him in relying more on powerful artillery fire than systematic earthworks. He introduced the Coehorn mortar. His "first system," which was employed at Mannheim (fig. 32), is reproduced for the sake of comparison with the Coevorden front designed a hundred years earlier. Among other points will be noticed the combination of wet and dry ditches; the very broad main ditch with counterguard; the roomy keep of the ravelin; the expansion of the fausse-braie into an independent low parapet; and the powerful flanking fire in three tiers.

The "tenaille" system and the "polygonal" system which grew out of it are mainly identified with the German school. That school, says von Zastrow, does not, like that of France, represent the authoritative teaching of an official establishment, but rather the general practice of the German engineers. It was founded on the principles of Dürer, Speckle and especially Rimpler, and much influenced in execution by Montalembert. The German engineers desired a simple trace, a strong fortification with retrenchments and keeps, bomb-proof accommodation and an organization suitable for an offensive defence.

These had always been the German principles. Already in the 16th century the Prussian defences of Kustrin, Spandau and Peltz had large bomb-proof casemates sufficient for a great part of the garrison. The same thing is seen in the defences of Giogau, Schweidnitz, &c., built by Frederick the Great. These works show various applications of the tenaille system. In 1776 Frederick became acquainted with the work of Montalembert, and his influence is seen in the casemates of Kosed.

Whether through the influence of Albert Dürer or not cannot be said, but while the bastion was being developed in France the tenaille and the accompanying casemates from the first found acceptance in Germany, and thence in eastern and northern Europe. De Groot, who wrote in 1618, produced a sort of tenaille system, and may have been the inspiration of Rimpler. Dillich (1630), Landsberg the elder (1648), Griendel d'Aach (1677), Werthmuller (1685) and others advocated both bastion and tenaille, sometimes in combination; the German bastion being usually distinguished by short faces and long flanks.

Rimpler, who was present at the siege of Candia (taken by the Turks in 1669) and died at that of Vienna in 1683, exercised a great influence. He had been struck by the weakness of the early Italian bastions at Candia, and published a book in 1673 called Fortification with Central Bastions, which was practically the polygonal trace. Zastrow thinks that Rimpler inspired Montalembert. He left unfortunately no designs to illustrate his ideas.

Landsberg the younger (1670-1746), a major-general in the Prussian service, who saw many sieges, also had a great influence. He appears to have been the first who frankly advocated the tenaille alone, chiefly on the ground that the flank, which was the most important part of the bastioned system, was also the weakest. Fig. 33 shows his system, published in 1712.

It was, however, ultimately a Frenchman, Marc René Montalembert (q.v.), who was the great apostle of the tenaille, though in his later years he leaned more to the polygonal trace. He objected to the bastioned trace on many grounds; principally that the bastion was a shell trap, that the flanks by crossing their fire lost the advantage of the full range of their weapons, and that the curtain was useless for defence. He took the view that the bastions with their ravelins constituted practically a tenaille trace, spoilt by the detachment of the ravelins and cramped by the presence of the curtains and flanks. His tenaille system consisted of redans, with salient angles of 60° or more, flanking each other at right angles; from which he gave to his system the name of "perpendicular fortification."

Lazare Carnot (q.v.), the "Organizer of Victory," was, in
fortification, a follower of Montalembert, and produced in 1797 a tenaille system (fig. 34) on strong and simple lines.

In 1812 Carnot offered three systems. For a dry and level site he recommended a bastioned trace; but for wet ditches and for irregular ground, tenaille traces. Both of these latter differ from his 1797 trace in that the re-entering angle is reinforced by a tenaille whose faces are parallel to the main faces and reach almost to the parapets. There are also countersgards in front of the salients, whose ends overlap the ends of the tenaille. (N.B. To avoid confusion between the tenaille trace and the tenaille, it should be noted that the latter is a low detached parapet placed in front of the escarp of the body of the place, partly as a shield, and partly as an additional line of defence. It is used in front of the curtain in the bastioned trace, and in the re-entering angle in the tenaille trace.)

Other important features of Carnot's work were: a continuous general reterracement, or interior parapet, following more or less the lines of the main parapet; the use of the detached wall in place of the escarpment; and the countersloping parapet of the bastions (of which Carnot was not the inventor), instead of sloping gently outwards from a crest raised about 8 ft. down to the natural level of the ground, sloped inwards from the ground-level to the bottom of the ditch. The advantage of the additional obstacle of the counterscarp was thus lost to the defence. On the other hand, the besiegers' saps, as they progressed down the glacis, were exposed to a plunging fire from the parapet.

Carnot was also, like Coehorn, a great believer in the mortar; but while Coehorn introduced the small portable mortar that bears his name, Carnot expected great results from a 13 in. mortar throwing 600 lb balls at each discharge. He endeavoured to prove mathematically that the discharge of these mortars would in due course kill off the whole of the besieging force.

These mortars he emplaced in open fronts, not in detached casemates, placed between the parapet of the reterracement and a detached wall.

The leading idea of Montalembert was that for a successful defence it was necessary for the artillery to be superior to that of the enemy. This idea led him to the adoption of casemates in several tiers, in preference to open parapets, exposed to artillery fire of all kinds, high angle, ricochet and reverse. In considering the defects of bastions he had arrived at the conclusion that for flanking purposes two forms of trace were preferable; either the tenaille form, connecting the revellings with the body of the place, or the form in which the primary flanking elements, instead of facing each other with overlapping fire, as with the bastions, should be placed back to back in the middle of the exterior side. Fig. 36 is an example of this. The central flanking work resulting from this arrangement is the caponier of the early Italians, reintroduced and developed; and with it Montalembert laid the foundation of the polygonal system of our own time.

Montalembert was one of the first to foresee the coming necessity for detached forts, and it was for these that he chiefly proposed to use his caponier flanking, preferring the tenaille system for large places. In abandoning the bastioned trace he was already committed to the principle of casemate defence for ditches; and the combination of this principle with his desire for an overwhelming artillery defence led him in the course of years of controversial writing into somewhat extravagant proposals. For instance, for a square fort of about 400 yds. side, he proposed over 1000 casemate guns; and one of his caponier sections shows 20 tiers of masonry gun-casemates one above the other. Confiding in the power of such an artillery, he freely exposed the upper parts of his casemates to direct fire. Montalembert is said to have contributed more new ideas to fortification than any other man. His designs may be considered in some ways unworkable and unsound, but all the best work of the 19th century rests on his teaching. The Germans, who already used the tenaille system and made free provision of bomb-proof casemates, took from him the polygonal trace and the idea of the entrenched camp.

The polygonal system in fortification implies straight or slightly broken exterior sides, flanked by casemated caponiers. The caponier is the vital point of the front, and is protected in these works by a revelling and keep. The essence of the system is its simplicity, which allows of its being applied to any sort of ground, level or broken, and to long or short fronts.

The final period of smooth bore artillery is an important one in the history of fortification. It is true that the many expensive works that were constructed at this time were obsolete almost as soon as they were finished; but this was inevitable, thanks to the pace at which the world was travelling. After the Napoleonic wars the Germanic Confederation began to strengthen its frontiers; and considering that they had not derived much strategic advantage from their existing fortresses, the Germans took up Montalembert's idea of entrenched camps, utilizing at the same time his polygonal system with modifications for the main enceintes. The Prussians began with the fortresses of Coblenz and Cologne; later Posen, Königsberg and other places were treated on the same lines. The Austrians constructed, among other places, Linz and Verona. The Germanic Confederation reinforced Mainz with improved works, and reorganized entirely Rastatt and Ulm. The Bavarians built Gersheim and Ingolstadt. While all these works were conceived in the spirit of Rimpler and Montalembert, they showed the differences of national temperament. The Prussian works, simple in design, relied upon powerful artillery fire, and exposed a good deal of masonry to the enemy's view. The Austrians covered part of their masonry with earth and gave more attention to detail.
The German development of the polygonal system at this time is not of great importance, since the great masonry casemates were designed without sufficient consideration for the increasing powers of artillery. One example (fig. 37) is given for the sake of historical comparison. It is a front of Posen.

The exterior side of the front is about 650 yds. (600 metres) long. It is flanked by a central casemate, which is protected by a detached bastion. The main front is broken back to flank the faces of the bastion from casemates behind the escarp, as well as from the parapet. The central casemate forms the keep of the whole front and sweeps back the interior and the ditch by its flanking fire. It has two floors of gun-casemates and one for musketry, and on the top is a parapet completely commanding all the outworks and the body of the place. It contains barrack accommodation for a battalion of 1,000 men, and has a large inner court enclosed by a detached wall. The caponier is itself flanked by three small caponiers at the head, and one at the inner end of each flank.

The escarp of the body of the place is a simple detached wall; that of the detached bastion is either a detached wall with piers and arches, or a counter-arched revetment. At the salient of the bastion there is a mortar battery under the rampart, and a casemated traverse for howitzers upon the terreplein. The flanks of the bastion are parallel to those of the caponier, and at the same distance from it as the faces.

The blockhouses, loopholed for musketry, are provided as keeps of the re-entering and salient places of arms. In the latter case they have stairs leading down into a counterscarp gallery, which serves as a base for countermine galleries and is connected with the detached bastion by a gallery under the ditch. The counterscarp is not revetted if the ditch is wet.

The angle of the polygon should not be less than 100°, in order that the prolongation of the main ditch may fall within the salients of the detached bastions of the neighbouring fronts, and the masonry of the caponiers may thus be hidden from outside view.” (R.M.A. Text-book of F. & M.E., 1886.)

We have now reached a period when the “detached fort” becomes of more importance than the organization of the enceinte.

The early conception of the rôle of detached forts in connexion with the fortress was to form an entrenched camp with arms and an army corps could seek safety if necessary. The idea had occurred to Vauban, who added to the permanent defences of Toulon a large camp defended by field parapets attached to one side of the fortress. The substitution of a ring of detached forts, while giving it the greater safety of permanent instead of field defences, gave also a wider area and freer scope for the operations of an army seeking shelter under the guns of a fortress, and at the same time made siege more difficult by increasing the line of investment.

The use of the detached fort as a means of protecting the body of the work from bombardment had not yet been made necessary by increased range of artillery.

When these detached forts were first used by Germany the scope of the idea had evidently not been realised, as they were placed much too close to the fortress. Those at Cologne, for instance, were only some 400 or 500 yds. in advance of the ramparts. The same leading idea is seen in most of these forts as in the new enceintes; i.e. a lunette, with a casemated keep at the gorge. The keep is the essential part of the work, the rampart of the lunette serving to protect it from frontal artillery fire. The keep projects to the rear, so as not only to be able to fire into it from the guns, but to be protected from them. A large number of caponiers works with guns protected from frontal fire. This is a valuable arrangement, which is still sometimes used. The front ditches of the lunettes were flanked by caponiers. Some of the larger forts were simple quadrangular works with casemate barracks and caponier ditch defence.

In 1830, in Austria, the archduke Maximilian made an entirely fresh departure with the defences of Linz. The idea was to provide an entrenched camp at the least possible cost, whose works should require the smallest possible garrison. With this object Linz was surrounded with a belt of circular towers spaced about 600 yds. apart. The towers, 25 metres in diameter, were enclosed by a ditch and glacis, and contained 3 tiers of casemates. The masonry was concealed from view by the ditch and glacis. On the top of the tower was an earth parapet, over which a battery of 13 guns fired en barbette. In order to find room for so many guns in the restricted space, the whole 13 were placed parallel and close together on a single specially designed mounting.

This new departure was received with a certain amount of approval at the time, which is somewhat difficult to account for, as a more faulty system could hardly be devised; but the experiment was never repeated.

The credit for much of the clear views and real progress made in Germany during this period is due to General von Brezen-Winiari, inspector-general of the Prussian engineers.

France, for a few years after 1815, could spare little money for fortifications, and nothing was done but repairs and minor improvements on the old lines. Belgium, having some money in hand, rebuilt and improved in detail a number of bastioned fortresses which had fallen into disrepair.

In 1830 France began to follow the lead of Germany with entrenched camps. The enceinte of Paris was reconstructed, and detached forts were added at a cost, according to von Zastrow, of £8,000,000. The Belgian and German frontiers of France being fairly protected by the existing fortresses, they turned their attention to the Swiss and Italian frontiers, and constructed three fortresses with detached forts at Belfort, Besançon and Grenoble. The cost of the new works at Lyons was, according to the same writer, £1,000,000 without the armament. Here and elsewhere the enceinte was simplified on account of the advanced defences. That of Paris, which was influenced by political considerations, was a simple bastioned trace with rather long fronts and without ravelins or other outworks; the escarp was high and therefore exposed, and the counterscarp was not revetted.

As regards the detached forts there was certainly a want of clearness of conception. Those of Paris were simply fortresses in miniature, square or pentagonal figures with bastioned fronts and containing defensible barracks. Those of Lyons were much more carefully designed, but the authors wavered between two ideas. Unwilling to give up the bastion, but evidently banking after the new caponiers, they produced a type which it is difficult to praise. The larger works were irregular four- or five-sided figures with bastioned fronts; and practically the whole interior space was taken up by a large keep, with its ditch, on the

---

**Fig. 38.**
polygonal system. The smaller works, instead of a keep, had defensible barracks in the gorge.

During the period 1855–1870 a considerable impulse was given to the science of fortification, both by the Crimean War and the arrival of the rifled gun. One immediate result of these was the condemnation of masonry exposed to artillery fire. The most important work of the period was the new scheme of defence of Antwerp, initiated in 1859.

This is chiefly interesting as giving us the last and finest expression of the medieval enceinte, at a time when the war between the polygonal and bastioned traces was still raging, though the boom of the long-range guns had already given warning that a new era had begun. Antwerp is also associated with the name of General Brialmont (q.v.), of the Belgian engineers, whom posterity will no doubt regard as the greatest writer on fortification of the latter half of the 19th century.

We give in figs. 38, 39 and 40 the general plan of the 1859 defences of Antwerp, the plan of a front of the enceinte, and its sections, as showing almost the last word of fortification before the arrival of high explosives.

The defences of Antwerp were designed, as the strategic centre of the national defence of Belgium, for an entrenched camp for 100,000 men. The length of the enceinte is about 9 m. The detached forts, which on the sides not defended by inundation are about 1½ m. apart and from 2 to 3 m. in front of the enceinte, are powerful works, arranged for a garrison of 1000 men. They have each a frontal crest-line of over 700 yds. and are intended for an armament of 120 guns and 15 mortars.

The general arrangement of the fronts of the enceinte should be compared with the earlier German type of Posen. It will be noticed that while the large casemated caponier at Posen breaks the enceinte and flanks it both without and within, at Antwerp the caponier is detached—a much sounder arrangement—and flanks the front only. The defence of the faces rests on the width of the wet ditches and on the flanking power of the caponier; there is no attempt to add to it by fausse-braie or detached wall. The dimensions are everywhere very generous, allowing free movement for the troops of the defence; the covered way is 22 yds.

Note. The reliefs are given in feet relatively to the plane of site (see above—bristl).

FIG. 39.

FIG. 40.—Sections of fig. 39.
wide and there is a double terreplein on the face. The parapet of the face is 27 ft. thick. The masonry of the casemate guns in the caponier, first flank and low battery, is protected by earth, à la Haxo.

In 1859 Austria acknowledged the influence of the new artillery with some forts at Verona. The detached forts built by Radetzky in 1848 were only from 1000 to 2000 yds. distant from the ramparts. Those now added, of which fig. 41 is an example, were from 3000 to 4000 yds. ont.

In the same year the land defences of some of the British dockyards were taken in hand. These first serious attempts at permanent fortification in England were received with approval on the continent, as constituting an advance on anything that had been done before. The detached forts intended to keep an enemy outside bombarding distance were roomy works with small keeps. The parapets were organized for artillery and the ditches were defended by caponiers or counterscarp galleries. The forts were spaced about a mile apart and arranged so as to support each other by their fire.

The sieges of the Franco-German War of 1870 are alluded to in the section below dealing with the "Attack of Fortresses."

As regards their effect on the designs of fortification the most important thing to note is the distance to which it was thought necessary to throw out the detached forts. These distances were of course influenced by the character of the ground, but for the most part they were very largely increased. Thus at Paris the fort at St. Cyr was 18,000 yds. from the enceinte; at Verdun the distances varied from 2500 to 12,000 yds.; at Belfort the new forts were from 4500 to 11,500 yds. out; at Metz 2300 to 4500; and at Strassburg 5200 to 10,000. One result of these increased distances was of course to increase very largely the length of the zone of investment, and therefore the strength necessary for the besieging force.

As regards the character of the works, the typical shape adopted both in France and Germany was a very obtuse-angled lunette, shallow from front to rear. The German type had one parapet only, which was organized for artillery and heavily traversed, the living casemates being under this parapet. The ditch defence was provided for by caponiers and a detached wall (see fig. 42).

The French forts had two parapets, that in the rear being placed over living casemates (in two tiers, as shown in the section of fig. 43 by a dotted line), and commanding the front one. There was a long controversy as to whether the artillery of the fort should be on the upper or the lower parapet, the advocates of the upper parapet attaching great importance to the command that the guns would have over the country in front. The other school, objecting to having guns on the skyline, preferred to sacrifice the command and place them on the lower parapet, as in fig. 43, the infantry occupying the upper parapet. It will be observed that the bastioned trace is abandoned, the ditches, like those of the German fort, being defended by caponiers.

While a great deal of work was done on these lines, a very active controversy had already begun on the general question as to whether guns should be employed in forts at all. Some declared that the accuracy and power of artillery had already developed so far, that guns in fixed and visible positions must needs be put out of action in a very short time. The remedy proposed by these was the removal of the guns from the forts into "wing-batteries" which should be less conspicuous; but soon the broader idea was put forward of placing the guns in concealed positions and moving them from one to another by means of previously prepared roads or railways. Others declared that there was no safety for the guns outside the forts, and that the use of steel turrets and disappearing cupolas was the only solution of the difficulty. General Brialmont, who had by this time become the first European authority on fortification questions, ranged himself on the side of the turrets. The younger
school were largely in favour of mobility and expressed themselves eagerly in a shower of pamphlets.

It was at this juncture that a new factor was introduced, namely, the obus-torpille, or long shell with high explosive bursting charge. With its appearance we say good-bye to the old school and enter upon the consideration of the fortification of to-day.

II. MODERN PERMANENT FORTIFICATION

Modern fortification dates by universal consent from 1883. The Germans had begun experiments a year or two before this, with long shell containing large charges of gun-cotton. But it was the experiments at Fort Malmaison in France in 1886 that set the military world speculating on the future of fortification. The fort was used as a target for 8-in. shell of five calibres length containing large charges of melanite. The reported effects of these made a tremendous sensation, and it was thought at first that the days of permanent fortification were over. Magazine casemates were destroyed by a single shell, and revetment walls were overturned and practicable breaches made by two or three shells falling behind them. It must be remembered, however, that the works were not adapted to meet this kind of fire. The casemates had enough earth over them to tamp the shell thoroughly, but not enough to prevent it from coming into contact with the masonry, and the latter was not thick enough to resist the explosion of the big charges. Other experiments were made in the same direction in Germany, Holland, Belgium and Austria. The Germans used shell containing from 60 to 130 lb of high explosive.

After the first alarm had subsided foreign engineers set about adapting their works to meet the new projectiles. Revetments were enormously strengthened, and designed so that their weight resisted overturning. Concrete roofs were made from 6 to 10 ft thick, and in many cases the surface of the concrete was left bare so as to expose a hard surface to the shell without any earth tamping. The idea of cupolas and shielded guns gained ground, and is now practically accepted all over the continent of Europe. In many cases the main armament, in some only the safety armament (see below), is in cupolas in the forts.

But meanwhile Europe had been flooded with literature on the subject, and the whole policy of fortification as well as its minutest details were discussed ab ovo. The extremists of both sides revelled in their opportunity. Some declared that, with the use of heavy guns and armour, fortresses could be made stronger than ever. Others held that modern fortresses were far too expensive, that their use led to strategic mistakes, and (arguing from certain well-known examples) that extemporized field defences could offer as good a resistance as permanent works.

---

**Fig. 44.—Metz in 1899.**

From Piessix and Legrand’s *Manuel complet de la fortification*, by permission.
European military opinion generally is now more or less agreed on the following lines:—

1. Important places must be defended by fortresses.
2. Their girdle of forts must be far enough out to prevent the bombardment of the place.
3. An enceinte is desirable, but need not be elaborate.
4. A few guns (called “safety armament”) should be in the forts, and these must be protected by armour.
5. The bulk of the artillery of the defence should be outside the forts; the direct-fire guns preferably in cupolas, the howitzers in concealed positions.
6. The forts should be connected by lines of entrenched infantry positions and obstacles, permanent bomb-proof shelters being provided for the infantry.
7. There should be ample communications—radial and peripheral—between the place and the forts, both by road and rail.
8. Special lines of communication—such as mountain passes—should be closed by barrier forts.

These considerations will now be taken somewhat more in detail, but first it will be useful to deal with the plan of Metz in 1859 (fig. 44).

Here the fortifications of successive periods can be readily recognized. First the old enceinte, unaltered by the Germans and now déclassé. Next the detached forts, begun by the French engineers in 1868 and still unfinished in 1870, can be readily recognized by their bastioned trace. Among these are Fort Manteuffel, forteres St-Julien, and Fort Goeben (fig. 45), formerly Queuleu. These were not altered in their general lines.

This early line of detached forts, less than 3000 yds. from the enceinte, was completed by the Germans with forts of polygonal type such as Fort Prinz August. The bill of St Quentin (fig. 46), a very important point, was converted into a fortified position, with two forts and connecting parapets, and a communication running north to Fort Alvensleben.

The arrangement of wing batteries in connexion with the forts can be clearly noted at Fort Manteuffel. These are reinforced by other batteries either for the defence of the intervals or to dominate important lines of approach such as the valley of the Moselle (canal battery at Montigny). To these were added later armoured batteries. There are also infantry positions, shelters and magazines in connexion with this line.

Finally some new forts of modern type were commenced in 1869 at about 3000 yds. from the place.

Leaving out of consideration at present the strategic use of fortresses, groups of fortresses, the places which, as mentioned above, are intrinsically worth being defended as fortresses are:—

(a) Centres of national, industrial or military resources.
(b) Places where the army can use as points d'appui for manoeuvres.
(c) Points of intersection of important railroads.
(d) Bridges over considerable rivers.
(e) Certain lines of communication across a frontier.

Examples of (a) are Paris, Antwerp, Lyons, Verdun. Again for (a) and (b), as is pointed out by Plessix and Legrand, Metz in the hands of the Germans may serve both as a base of supplies and a point d'appui for one flank. Strassburg is a bridge-head giving the Germans a secure retreat across the Rhine if beaten in the plains of Alsace, and an opportunity of resuming the offensive when they have re-formed behind the river.

The distance of detached forts from the place depends on the range of the siege artillery and the distance at which it can usually be established from the forts, and is variously given by different continental writers at from 4 to 9 km. (4500 to 10,000 yds.). The bombarding range of siege howitzers with heavy shells is considered to be about 8000 yds., and if it is possible for them to be emplaced within say 2000 yds. of the forts this would give a minimum distance of 6000 yds. from the forts to the body of the place. Some writers extend the minimum distance to 7 km., or nearly 8000 yds.

In practice, however, it must happen that the position of the forts is determined to a very large extent by the lie of the ground. Thus some good positions for forts may be found within 4000 or

From Plessix and Legrand's Manuel complet de la fortification, by permission.

**Fig. 45.—Fort Goeben, Metz.**

**Fig. 46.—St Quentin position, Metz.**

5000 yds. of the place, and no others suitable on the same front within 15,000 yds. In that case the question of expense might necessitate choosing the nearer positions. Some examples of the actual distances of existing forts have already been given. Others, more recent, are, at Bucharest 7-10 km., Lyons 8-105, Copenhagen 7-8 and Paris 14-17. Strategic pivots are in a different category from other fortresses. While not necessarily protected from bombardment, they may yet have one or two forts thrown out from 9 to 12 km., to get advantage of ground. Such are Langres, Epinal and Belfort.

The Enceinte.—The desirability of this is almost universally allowed; but often it is more as a concession to tradition than for any solid reason. The idea is that behind the line of forts, which is the main defensive position, any favourable points that exist should be provisionally fortified to assist in a "step-by-step" defence; and behind these again the body of the place should be surrounded by a last line of defence, so that the garrison may resist to the last moment. It may be remarked that apart from the additional expense of an enceinte, such a position would not, under modern conditions, be the most favourable for the last stages of a defence. Again, there is the difficulty that it is practically impossible to shut in a large modern town by a continuous enceinte. It has been proposed to construct the enceinte in sections in front of the salient portions of the place. This system of course abandons several of the chief advantages claimed for an enceinte.

In actual practice enceintes have been constructed since 1870 in France and other countries, consisting of a simple wall 10 or 12 ft. high with a banquette and loopholes at intervals. This course can only be looked upon as a measure of police. For war purposes, in face of modern artillery, it is a reductio ad absurdum.

The Safety Armament.—If the bulk of the artillery is to be placed in positions prepared as the ultimate line of defence, it is considered very necessary that a few heavy long-range guns should be permanently in position ready at any moment to keep an enemy at a distance, forcing him to open his first batteries at long range and checking the advance of his investment line. Such guns would naturally be in secure positions inside the forts, and if they are to be worked from such positions they must have armour to shield them from the concentrated fire of the numerous field artillery that a besieger could bring to bear from the first.

Artillery outside the forts constitutes the most important part of the defence, and there is room for much discussion as to whether it should have positions prepared for it beforehand.
or should be placed in positions selected as the attack develops itself. On the one hand the preparation of the positions beforehand, which in many cases means the use of armour and concrete, increases very largely the initial expense of the defence, and ties the defender somewhat in the special dispositions that become desirable once the attack has taken shape. Moreover, such expenditure must be incurred on all the fronts of the fortress, whereas the results would only be realized on the front or fronts actually attacked. On the other hand much time and labour are involved in placing heavy and medium artillery with extemporized protection, and this becomes a serious consideration when one remembers how much work of all kinds is necessary in preparing a fortress against attack. Again, to avoid the danger of a successful attack on the intervals between the forts before their defences have been fully completed, the fire of the guns in the intermediate positions might be urgently required. The solution in any given case would no doubt depend on the importance of the place. In most cases a certain amount of compromise will come in, some preparation being made for batteries, without their being completed. Armoured batteries of whatever kind must in any case be prepared in peace time. It should not be overlooked that as, whatever theories may exist about successive lines of defence, theonus of the defence will now lie on the fort line, just as it formerly did on the enceintes, so that line should be fully prepared, and should not have to commence its fight in a position of inequality.

Defence of Intervals of Forts.—The frontal fire of the batteries in the intervals and the flanking fire of some of the guns in the forts will play an important part, but the main reliance should be on infantry defence. A fully prepared fortress would have practically a complete chain of infantry fighting positions and obstacles between the forts, at all events on the fronts likely to be seriously attacked. The positions would consist largely of fire trenches, with good communications; but it is pretty generally recognized that there must be some points d'appui in the shape of redoubts or infantry forts, and also bomb-proof shelter for men, ammunition and stores near the fighting line. This is usually included in the redoubts. If they are to resist the heaviest shell, such shelters must be built in peace time.

Communications are of the first importance, not merely to facilitate the movement of the enormous stores of ammunition and materials required in the fighting line, but also that defenders may fully utilize the advantage of acting on interior lines. They should include both railways and roads running from the centre of the place to the different sectors of defence, and all round, in rear of the line of forts; also ample covered approaches to the fighting line. Concealment is essential, and where the lie of the ground does not help, it must be got from earth parapets or plantations.

The principal use of barrier forts is in country where the necessary line of communication cannot be easily diverted. For instance, in a comparatively flat country a barrier fort commanding a road or railway is of little use because roads may be found passing round it, or a line of railway may be diverted for some miles to avoid it. But in mountainous country, where such diversion is impossible, it will be necessary for the enemy to capture the fort before he can advance; and the impossibility of surrounding it, the few positions from which siege artillery can be brought into play, and the fact that there is practically only one road of approach to be denied, make these positions peculiarly suitable for forts with armoured batteries. Italy makes considerable use of such forts for the defence of frontier passes.

Before going into details, it is worth while to state the full claim of strategic fortification advanced by General Brialmont, the most thorough of all its advocates. It is as follows:

A. Fortify the capital.
B. Fortify the points where main lines of communication pass a strategic barrier.
C. Make an entrenched camp at the most important centre of communication in each zone of invasion; and support it by one or two places arranged so as to make a fortified district.

FIG. 47.
D. Close with barrier forts the lines necessary to an enemy across mountains or marshes.
E. Make a central place behind a mountain chain as a pivot for the army watching it.
F. Defend mountain roads by provisional fortifications.

G. Make a large place in each theatre of war which is far from the principal theatre, and where the enemy might wish to establish himself.
H. Fortify coasts and harbours.

Objections to these proposals will be readily supplied by the
officials of the national treasury and the commanders-in-chief of the active armies.

So many types of detached forts have been proposed by competent authorities, as well as actually constructed in recent years, that it is impossible here to consider all of them, and a few only will be reproduced of those which are most representative of modern continental thought.

Taking first the type of heavily armed fort, which contains guns for the artillery fight as well as safety armament, we must go back to General Brialmont. The forts works here shown are taken from the Progrès de la défense des états, &c., published in 1898. The pentagonal fort (fig. 47) has two special features. In section 1 is shown a concrete infantry parapet, with a gallery in which the defenders may take shelter from the bombardment preceding an assault. In section 2 it will be seen that the counterscarp galleries flanking the ditch are drawn back from the face of the counter-scarp in a semi-circular line, and that, while there is no covered way under the parapets, the defenders are protected by throwing smoke-producing materials into the ditch. In section 3 is shown the arrangement of the casemates and the gun-cupolas, which are arranged as shown at (a) and (b), the former on the face of the citadel, the latter on the counter-scarp gallery. There the machine guns are mounted on a single casemate on either side of the covered way. The observatory is elevated in the same way as in the casemates. From Brialmont’s Progrès de la défense des états, &c., by permission of Commandant G. Meeks.

The following points may be noticed about this design in comparing it with earlier types. There is no escarp, the natural slope of the rampart being carried down to the bottom of the ditch. There is a counterscarp to the faces, but no covered way. The flank gallery, which is cut in the back of the ditch, is cut in the course of the ditch and the covered way which is utilized for a wire entanglement and is under the fire of the parapet. In this design there is a very slight bastioned indentation, which allows for an efficient flanking of the ditch by a couple of machine guns placed in a single casemate on either side.

The abolition of the covered way as such is noteworthy. It points to an essential difference between the fort and the old enceinte profiles; showing that offensive action is not expected from the garrison of the fort, and is the duty of the troops of the intermediate lines.

The great central mass of concrete containing all the casemates and the gun-cupolas, a very popular feature, is omitted in this design, advantage being taken of the great lateral extent of the fort to spread the casemates under the faces, flanks and gorge, with a communication across the centre of the fort. This arrangement gives more freedom to the disposition of the cupolas. The thickness of the concrete over the casemate arched mortar work is more than eight. Communication between the faces and the counterscarp galleries is obtained by posterns under the ditch, a feature of great simplicity and power. This fort is a great advance on General Brialmont’s designs before 1885. These were marked by great complexity of earth parapets and various châtaignes which would not long survive bombardment.

This fort is simple and powerful.

The second Brialmont fort (fig. 48) is selected because it shows a keep or citadel, an inner work designed to hold out after the capture of the outer parapet. General Brialmont holds strongly to the medieval plan. The history of course gives many instances of citadels which have enabled the garrison to repel the main work with assistance, or cause a really useful delay in the progress of the general attack. It affords still more instances in which the keeps have made no resistance, or none of any value. Some think that the existence of a keep encourages the defenders of the main work; others that it encourages the idea of retreat. The British school of thought is against keeps. In any case they add largely to the expense.

In the present design the keep is a mass of concrete, which depends for its defence on the ditch and galleries only. The counterscarp gallery in the main work, the few embrasures for flank defence being practically useless. Its main function is to prevent the attackers from establishing themselves on the gorge, thus leaving the way open for a retreat to the citadel, or to enter (assisted by flying bridges) through the passages left for the purpose in the outer and inner gorge parapets.

As regards the main work, the arrangements for defence of the ditch and its armament are similar to the last design considered.

This parapet has no concrete shelter for the defenders. The casemates are all collected in the keep and the gorge, with a passage all round giving access to the parapet and the cupolas.

Fig. 49 is a German work, Fort Molsheim at Strassburg. This is a quadrangular type of triangular fort. The main mass of concrete rests on the gorge, and is divided by a narrow courtyard to give light and air to the front casemates. The fort has a medium armament for the artillery fight, consisting of four 6-in. howitzers in cupolas. On each face are two small Q.F. guns in cupolas for close defence, for which purpose, it will be seen, there is also an infantry parapet. At the angles are look-out turrets. The ditch has escarp and counterscarp, and is defended by counterscarp galleries at the angles. There is no covered way. The thickness of concrete over the casemates, where it is uncovered, is about 10 ft.

Fig. 50 is Fort Lyngby at Copenhagen. The new Copenhagen defences are very interesting, giving evidence of clear and original thought, and effectiveness combined with economy. There is one special feature worth noting about the outer ring of forts, of which this is one. These works are intended for the artillery fight only, their main armament being four 6-in. guns (in pairs) and three 6-in. howitzers, all in cupolas. The armament for immediate defence is trifling, consisting of only two 87-mm. guns and a machine-gun. There is no provision for infantry defence. The ditch has no escarp or counterscarp, and is flanked by counterscarp galleries at the salient.

It is usual in the case of works so slightly organized for their own defence, and intended only for the long-range artillery fight, to withdraw them somewhat from the front line. The Danish engineers, however, have not hesitated to put these works in the very front line, some 2000 metres in front of the permanent intermediate batteries. The object of this is to force the enemy to establish his heavy artillery at such long ranges that it will be able to afford little assistance to the trench attack of the infantry. The intermediate batteries, being withdrawn, are comparatively safe. They therefore do not require expensive protection, and can reserve their strength to resist the advance of the attack. The success of this arrangement will depend on the fighting strength of the cupolas under war conditions; and what that may be, war alone can tell us.

In the details of these works, besides the bold cutting down of defensive precautions, we may note the skilful and economical use of materials in the casemates to diminish the thickness of concrete required. The roofs of the casemates are stiffened underneath with steel rails, and steel lathing is used to prevent lamps of concrete from falling on the occupants. The living casemates look out on the gorge, showing plenty of light and air, while the magazines are under the cupolas.

The forts above described are all armed with a view to their taking an important part in the distant artillery fight. The next type to be considered (fig. 51) is selected mainly because it is a good example of the use of concealed flanking batteries, known on the continent as batteries traditoires, which seem to be growing in popularity.

This design by Colonel Voordeijn of the Dutch engineers has a
FORTIFICATION AND SIEGECRAFT

medium armament, which is not intended for the artillery duel, but to command the immediate front of the neighbouring forts and the intervals. The fort is long and narrow, with small casemate accommodation. It contains eight 4.7-in. guns. Two of these are in a cupola concealed from view, though not protected, by a bank of earth in front. The other six are in an armoured battery behind the cupola. It may be remarked that as the cupola gets no real protection from the covering mass of earth, it would be better to be able to utilize the fire of its guns to the front. The batterie tradition, if properly protected, would be very difficult to silence, and its flanking fire would probably be available up to the last moment. There is very much to be said both for and against the policy of so emplacing the guns. The immediate defence of the work, with the aid of a broad wet ditch, is easy; but the great mass of concrete, which is intended to form an indestructible platform and breastwork for the infantry, would seem to be a needless expense.

Fig. 52, designed by the Austrian lieutenant field-marshal Moritz Ritter von Brunner (1839-1904), is selected as a type of the intermediate fort which is intended only to be a strong point in the infantry line of defence between the main forts. It has a protected armament, but this, which consists only of four small Q.F. guns in cupolas, is for its own defence, and not to take part in the artillery duel. There is also a movable armament of four light Q.F. guns on wheels, for which a shelter is provided between the two observatory cupolas. The garrison would be a half company of infantry, for whom casemates are provided in the gorge. The gorge ditch is flanked by a casemate, but there is no flank defence for the front ditch. This is defended by a glacis parapet. At the bottom of the ditch is a wire entanglement and the glacis slope is planted with thorns. The thickness of concrete on the casemates is 2 metres (6 ft. 7 in.). This is a strong and simple form of infantry work, but considering its rôle it appears to be needlessly expensive.

From Brilmont's Progrès de la défense des États, &c., by permission of Commandant G. Moïus.

FIG. 50.—Fort Lyngby, Copenhagen.
Fig. 53 is an Italian type of barrier fort in mountainous country. A powerful battery of eight medium guns protected by a Gruson shield commands the approach. The fort with its dwelling casemates is surrounded by a deep ditch flanked by counterscarp galleries. There are certain apparent weaknesses inherent in the type, but the difficulties of the attack in such country and its limitations must be borne in mind.

Modern Details of Protection and Obstacle.—After considering the above types of fort, it will be of use to note some of the details in which modern construction has been modified to provide against the increasing power of artillery.

The penetration of projectiles varies according to the nature of the soil—the lighter the better for protection. Sand offers the greatest resistance to penetration, clay the least. Since, however, the penetration of heavy shells fired from long ranges with high elevation may be 20 ft. or more in ordinary soil, we can no longer look to earth alone as a source of protection against bombardment. Again a moderate quantity of earth over a casemate increases the explosive effect of a shell by "tamping" it, that is by preventing the force of the explosion from being wasted in the open air.

We find therefore that in most modern designs the tops of casemates are left uncovered, or with only a few inches of earth over them, in which grass may be grown for concealment.

For the materials of casemates and revetment walls exposed to fire, concrete (q.v.) has entirely replaced masonry and brickwork, not because of its convenience in construction, but because it offers the best resistance. The exact composition of the concrete is a matter that demands great care and knowledge. It should be, like an armour plate, hard on the surface and tough within. The great thickness of 10 ft. of concrete for casemate arches, very generally prescribed on the continent in important positions, is meant to meet the danger of several successive shells striking the same spot. To stop a single shell of any siege calibre in use at present, 5 ft. of good concrete would be enough. A good deal is expected from the use of "reinforced concrete" (that is concrete strengthened by steel) both for revetment walls and casemates.

Parapets are frequently made continuous or glacis-wise, that is the superior slope is prolonged to the bottom of the ditch so that the whole rampart can be swept by fire from the defenders from the crest, and there is no dead ground in front of it. It is also common to build the crest of the parapet in solid concrete, with sometimes a concrete banquette, so that bombardment shall not destroy the line the defenders have to man in repelling an assault. This concrete parapet may be further reinforced by hinged steel bullet-proof plates, to give head cover; which when not in use hang down behind the crest.

The escarp is falling into disfavour, on account of the great expense of a revetment that can withstand breaching fire. A counterscarp of very solid construction is generally used. It is now and gives cover to a wire entanglement in the ditch. This may be supplemented by a steel unclimbable fence, and by entanglements or thorn plantations on the covered way and the lower slopes of the parapet. Entanglements are attached to steel posts bedded in concrete. The upper parts of revetments and the foundations of walls are protected against the action of shells, that falling steeply might act as mines to overturn them, by thick aprons of large stones. Fig. 54 shows most of these dispositions.

Electric search-lights are now used in all important works and batteries. They are usually placed in disappearing cupolas. They are of great value for discovering working parties at night, and lighting up the foreground during an attack; and since only the projector need be exposed, they are not very vulnerable. Their value, however, must not be over-estimated. The most powerful search-light can in no way compare with daylight as an illuminant, and, like all other mechanical contrivances, they have certain marked drawbacks in war. They may give rise to a false confidence; an important light may fail at a critical moment; and in foggy weather they are useless.

The use of armour (see also Armour-Plates) for coast batteries followed closely upon its employment for ships, for those were the days of short ranges and close fighting, and it seemed natural not to leave the battery in a position of inferiority to
the ship in the matter of protection. In England the coast battery for a generation after the Crimean War was a combination of masonry and iron; and in 1850 Brialmont employed armoured turrets at Antwerp which commanded the Scheldt. For land defence purposes, however, engineers were very slow to adopt armour. Apart from all questions of difficulty of manufacture, expense, &c., the idea was that sea and land fronts were radically different. It was pointed out that a ship gun, fired from an unsteady platform, had not enough accuracy to strike repeated blows on the same spot; so that a shield which was strong enough to resist a single shot would give complete protection. A battery on a land front, on the other hand, was exposed to an accurate fire from guns which could strike successive blows on the same spot, and break down the resistance of the strongest shield. But in time continental opinion gradually began to turn in favour of iron protection. Practical types of disappearing and revolving cupolas were produced, and many engineers were influenced in their favour by the effect of the big high-explosive shell. Eventually it was argued that, after all, the object of fortification is not to obtain a resisting power without limit, but to put the men and guns of a work in an advantageous position to defend themselves as long as possible against a superior force; and that from this point of view armour cannot but add strength to defensive works.

The question has of course long passed beyond the stage of theory. Practically every European state uses iron or steel casemates and cupolas. German, Danish, Italian and other types of forts so armed have been shown. Recent French types have not been published, but it is known that cupolas are employed; and Velichke, the Russian authority, long an uncompromising opponent of armour, in the end changed his views. These countries have had to proceed gradually, by improving existing fortresses, and with such resources as could be spared from the needs of the active armies. Among the smaller states Rumania and Belgium have entered most freely into the new way. In England, which is less directly interested, opinion has been led by Sir George Clarke, since the publication in 1850 of his well-known book on fortification. Having witnessed officially the experiments at Bucharest in 1855 with a St Chamond turret and a Gruson cupola, he expressed himself very strongly against the whole system. Besides pointing out very clearly the theoretical objections to it, and the weak points of the constructions under experiment, he added: “The cost of the French turret was about £10,000 exclusive of its armament, and for this sum about six movable overbank guns of greater power could be provided.” In view of the weight that belongs of right to his criticisms it is as well to point out that while this remark is quite true, yet the six guns would require also six gun detachments, with arrangements for supply, &c.; a consideration which alters the working of this apparently elementary sum. The whole object of protection is to enable a few men and guns successfully to oppose a larger number.

At the time when Sir George Clarke’s first edition came out, such extravagances were before the public at Mougin’s fort; “a mastless turret ship,” as he called it, “buried up to the deck-level in the ground and manned by mechanics.” Such ideas tended to throw discredit on the more reasonable use of armour, but whether the system be right or wrong, it exists now and has to be taken account of. Nowhere has it been applied more boldly than in Rumania. The defences of Bucharest (designed by Brialmont) consist of 18 main and 18 small forts, with intermediate batteries. The main forts are some 4500 yds. apart, and 11,000 to 12,000 yds. from the centre of the place. The typical armament of a main fort is six 6-in. guns in three cupolas (one for indirect fire), two 8·4-in. howitzers in cupolas, one 4·7-in. howitzer in a cupola, six small Q.F. guns in disappearing cupolas. The total armament of the place (all protected) is eighty-six 6-in. guns, seventy-four 8·4-in. howitzers, eighteen 4·7-in. howitzers, 137 small calibre Q.F. guns in disappearing cupolas, 476 small calibre Q.F. guns in casemates for flanking the ditches. The “Sereth Line” will be described later.

Different Forms of Protection: Casemate, Cupola, &c.—The broad difference between casemates or shielded batteries and turrets and cupolas is that the former are fixed while the latter revolve and in some cases disappear. The casemate thus has the disadvantages that the arc of fire of the gun, which has to fire through a fixed embrasure or port-hole, is very limited, and that the muzzle of the gun and the port-hole, the weak points of the system, are constantly exposed to the fire of the enemy. The advantage of the casemate lies in its comparative cheapness and the greater strength of a fixed structure. It is well suited for barrier forts (fig. 53) and other analogous positions; and the Italians amongst other nations have so employed it at such places as the end of the Mont Cenis tunnel. Steel and iron casemates are also useful as caissons for ditch flanking (fig. 55).

Turrets and Cupolas.—The difference between a turret and a cupola is that the former is cylindrical with a flat or nearly flat top and presents a vertical target; while the latter is a flattened
done, the vertical supports of which are entirely concealed. The
turret appears to be little used. The object of both forms is at
once to give an all-round arc of fire to the guns and to allow of
the weak point of the structure, the port-hole and muzzle of
the gun, being turned away from the enemy in the intervals of
firing. Both usually emerge from a mass of concrete, which is
strengthened round the opening by a collar of chilled cast iron
about 12 to 15 in. thick.

There are four types of cupolas, viz. (a) Disappearing, (b)
Oscillating, (c) Central pivot, (d) On roller rings.

(a) Disappearing cupolas are used chiefly for small quick-firing
guns, on account of the expense of the various systems. They
can be used for medium guns. The details of the best foreign
systems are secret. (b) The oscillating turret is a Mougin
type, in which the turret is supported in the centre by a knife-edge
on which it can swing. The oscillation is controlled by powerful
springs. The effect of it is that after firing, the front of the cupola
with the port-hole swings downwards under cover, and is held there
until the gun is ready to fire again. (c) Schumann’s centre pivot is
understood to be approved in Germany. It has been adopted in
Rumania and Belgium for howitzer cupolas. It is only suitable for
a single piece; $d$ is strong and steady—the best cupola for coast
batteries; $c$ and $d$ are best for rapid fire because they can be loaded
without lowering. They are suited for long guns.

The following types are illustrated as being generally representative
of the different classes of cupola.

Fig. 56 is a section of Messrs Krupp’s typical cupola for one 6-in.
gun. The shield is of nickel steel, the collar of cast steel. A small
space is left between the cupola and its collar to prevent the possi-
bility of the shield jamming after being damaged. The guns are
muzzle-pivoting and are thickened out near the muzzle by the addition
of a ring, so as to close the port as much as possible. The recoil
is controlled within narrow limits both to economize space and to
prevent the smoke from the muzzle from getting into the cupola.
To facilitate the elevation and depression of the gun (with muzzle
pivotings the breech has of course to be moved through a much larger
arc than with ordinary mountings) it is balanced by a counterweight.
The cupola rests on a roller ring and is traversed by a winch. It can
be turned through a complete circle in about one minute.

Fig. 57 shows a Schumann shielded mortar (sphere-mortar,
Kugelmörser). In this case it will be observed that the cupola is
replaced by an enlargement of the encircling collar; and the mortar
(6.4-in. calibre) is enclosed in a sphere of cast iron, so as to close
completely the opening of the collar in any position.

Fig. 58 shows a Gruson cupola for one 4.7-in. Q.F. howitzer.

Fig. 59 shows a disappearing turret for an electric light projector.
Fig. 60 shows a Krupp transportable cupola for a 57-cm. gun.
This is drawn on a four-wheeled carriage, and when coming into
action slides on rollers on to a platform in the parapet. It weighs
about 23 tons, and with carriage and platform about 4 tons.

From Leithner’s Beständige Beschießungen.

The mechanism of these cupolas is for the most part simpler than it
appears. Counterweights and hand winches are much in use for the
lighter natures of guns. The armoured of course keeps pace
with improvements in manufacture. The chilled cast iron first
made popular by the Gruson firm is now little used except for such
purposes as the collar round a cupola. wrought iron, steel and
compound plates for the tops of cupolas have all been tried, the most
recent Krupp-Gruson designs being of nickel steel.

The sighting in some cases may be done by sights on the gun, with
suitable enlargements in the port-hole; in others by sights affixed to the cupola
itself (which of course can give horizontal direction only); in others training
and elevation are given in accordance with the readings on electric dials, or instruc-
tions by telephone or speaking tube. There is of course nothing unreasonable
in this in the case of indirect fire guns and howitzers, for if not firing from
cupolas they would be behind the shelter of some wood or
quarry.

Schumann’s System: “Armoured
Fronts.” — Lieut.-Colonel Maximilian
Schumann (1827-1896) of the Prussian
engineers, who took a very prominent part
in the design and advocacy of armoured
defences, eventually produced a
system which was used by some
forts and relied on the fire of protected
guns. It consists of several lines of bat-
teries for Q.F. guns and howitzers in
cupolas. He considered that such bat-
teries would be able to defend their own
front, and the infantry garrison was not
to be called into action except in the
case of the enemy breaking through at
some point of the line.

This system was actually adopted by
Rumania (1889-1899) for the Sereth Line.
There are three routes by which the
Russians can enter the country across the
Sereth river: through Focshani, Nemo-
loasa and Galatz. These three
routes are barred by bridge-heads, those
at Focshani, the most important, being
on the left bank of the Milkov, a tributary
of the Sereth.

The Focshani works consist of 71
batteries arranged on a semicircular front about 12 in. long and
from 8,000 to 10,000 yds. in advance of the bridges. The batteries
are placed in three lines, which are about 500 yds. apart, and are
subdivided into groups. The normal group consists of 5 batteries,
of which 3 are in the first line, 1 in the second, and 1 in the third.
The first-line batteries each contain five small Q.F. guns in travelling
cupolas. The second-line batteries, each six small Q.F. guns in disappearing cupolas. The third-line batteries have one 120-mm. gun in a cupola, and two 210-mm. spherical mortars with Gruson shields. The immediate defence of the batteries consists of a glacis planted with thorn bushes and a wire entanglement.

The fortification of these three bridge-heads are said to have cost about £1,100,000. But the system of "armoured fronts" is never likely to be reproduced, having been condemned by all authoritative continental opinion. Its defects have been summarized by Schroeter as follows: weakness of artillery at long ranges, want of security against a surprise rush, the neglect of the use of infantry in the defence, and the difficulty of command. This last is the most serious of all. It is indeed difficult to conceive that any one should expect half-a-dozen expert gunners, each shut up in an iron box with a gun, to stop the rush of a thousand men, even by day. But imagine the feelings of the gunner on the night of a big attack, alone in his box, his nerves already strained by a preliminary bombardment and nights of watching. He hears the sounds of battle all around; he knows nothing of the progress of the attack, but expects everything, and feels every moment the door of his box being opened and the bayonet entering his buck. No wise commander would submit his troops to such a test.

Sir George Clarke and Unarmoured Systems.—Before leaving the subject of fortresses it is necessary to consider the ideas of those who, while recognizing the necessity for places permanently organized for defence, prefer to treat them more from the point of view of perfected field defence. It is to the credit of English military science that Sir George Clarke may be taken as the representative of this school of thought. His study of fortification, as he tells us, began with a history of the defence of Plevna (q.v.). He was led to compare the resistance made behind extemporized defences at such places as Sevastopol, Kars and Plevna, with those at other places fortified in the most complete manner known to science. From this comparison he drew the conclusion that the true strength of fortification does not depend on great masonry works intricately pieced together at vast expense, but on organization, communications and invisibility. In his 1907 edition he says:

"Future defences will divide themselves naturally into the following categories: (1) Permanent works wholly constructed in peace time and forming the key points of the position. (2) Gun emplacements, magazines and shelters for men in rear of the main line, all concrete structures and platforms to be completed, though some earthwork may be left until the position is placed in a state of defence. (3) Field works, trenches, &c., guarding the intervals between the permanent defences in the main line, or providing rear positions. These should be deliberately planned in time of peace ready to be put in hand at short notice. The essence of a well-fortified position is that the weapons of the defender shall obtain the utmost possible scope of action, and that those of the attacker shall have the minimum chances of effecting injury."

Since Sir George Clarke published his first edition in 1890 continental ideas have expanded a good deal. The foregoing statement as to the three categories of defences would be accepted anywhere now: the differences of opinion come in when we reach the stage of classifying under the first head the permanent works to be constructed in peace time. In most countries these would include forts with guns for the artillery duel, forts with safety armaments, fixed batteries with or without armour, and forts for infantry only. Sir George Clarke will have no armour for guns except in certain special cases of barrier forts. Heavy guns and howitzers requiring permanent emplacements (concrete platforms, &c.) must either be well concealed or be provided with alternative positions. The only permanent works which he admits are for infantry. They are redoubts of simple form intended for 350 or 400 men, with casemate accommodation for three-fourths of that number. Fig. 61 shows the design—two rows of casemates, one under the front parapet, one under a parados; frontal musketry defence; obstacle consisting of entanglements, mines, &c., with or without escarp and countergarde.

"The intervals (he says) between the infantry redoubts may be about 2500 yds.; but this will necessarily depend upon the conformation of the ground. Where there are good artillery positions falling within the sphere of protection of the redoubts, large intervals will be permissible. Thus, in the case of an extended line of defence where the ground offers marked tactical features, the idea of a continuous chain of permanent works may be abandoned in favour

---

**Fig. 60.** Transportable Cupola for 57-cm. Gun (Friedr. Krupp A.G.).
of groups of redoubts guarding the artillery positions. In this case, the redoubts in a group might be distributed on a curve bent back in approximately horse-shoe form."

The keystones of the close defence of the fighting line in future will undoubtedly be these infantry redoubts, and therefore it is of great interest to compare with the above types two studies put forward by Schroeter (Die Festung in der heutigen Kriegführung), one in his first edition in 1898 (fig. 62), and the other in the second in 1905 (fig. 63). In both these the defensive arrangements are merely trenches of field profile with entanglements, the command and the obstacle being less than in Sir George Clarke's work; and it will be noticed that in the 1905 type, published after the Russo-Japanese War, the plan is much less simple and arrangements for close flanking defence have been introduced. But these works of Schroeter's are merely infantry supporting points in a line which contains forts of the triangular type with guns, and armoured batteries, as well as a very complete arrangement of field defences and communications; while Sir G. Clarke's redoubts are the only permanent works giving casemate protection in the front line.

The comparative merits of either design for an infantry redoubt are not of much importance. It is agreed that the main line of defence must consist of a more or less continuous line of field defences and obstacles, and that at some points in the line there should be infantry supporting points with bomb-proof protection capable of resisting big shells. The open question is, what additional works, if any, are required for the artillery, whether for the medium and heavy guns that will take part in the "artillery duel," or for the lighter nature's that will help in the close fight and defence of the intervals. Is it best for the defenders to rely on armoured protection or on concealment for his guns?

Official opinion outside England has certainly sanctioned armour, since all over the continent it is to some extent adopted in practice. National practice is usually based on the advice of the most distinguished officers of the day, and therefore it is unsafe to condemn it hastily. Sir George Clarke and those who are with him—and they are many, both in Great Britain and abroad—object entirely to armour. He says (Fortification, ed. 1907, p. 96): "The great advantage possessed by the attack in all ages has been the employment of a mobile artillery against armaments cribbed, cabined and confined by fortification. It is necessary to perpetuate this advantage." Of course the effect of long-range weapons, in increasing the length of front that can be held by a given force, has given much greater
The freedom of action to the defence and this should be taken full advantage of. The argument as to the vulnerability of shielded guns is not at present strong. Sir George says (ib. p. 94), "If the high angle fire is ever to find a favourable opportunity, it will surely be against a cupola, the site of which can generally be determined with accuracy." On the other hand he says (p. 90), "During the long and costly experiments carried on at Bucharest in 1885-1886, 164 rounds were fired from the Krupp 21 cm. mortar at targets of about 40 sq. metres area "(about 430 sq. ft.) "without obtaining a single hit. The range was 2700 yds.; the towers were built upon a level plain; the shooting conditions were ideal, and the fall of each shell was telephoned back to the firing point; but it must have been evident to the least instructed observer that to attempt to group 6 or 8 shells on an invisible area 2 metres square would have been absolutely futile." These facts are added to prove that it is not necessary to give great thickness to concrete casemates, to resist successive bursts of shells in the same place; but surely they are equally applicable to cupolas. Again (p. 252), "The experience gained at Port Arthur was not altogether encouraging as regards the use of high angle fire. The Russian vessels in the harbour were sunk by opening their sea-valves... Fire was subsequently directed upon them from 11 in. howitzers at ranges up to about 7500 yds. This was deliberate practice from siege batteries at stationary targets, but the effect was distinctly disappointing." The cupolas therefore can hardly be considered ideal targets: and the probability is that they would hold their own against both direct and indirect fire for a long time. There are other advantages, and stronger arguments against the general use of them, all of which are clearly set forth by Sir George Clarke.

The worst objections to the cupola are the military disadvantages of isolation and immobility, and the multiplication of mechanical arrangements. For a successful round from a disappearing cupola, the elevating and traversing arrangements, the elevating and loading gear of the gun, and the telephone communication, must all be in good order. At night the successful co-operation of the searchlight is also in many cases necessary.

The teaching of history is all against immobile mechanical defences. Initiative, surprise, unforeseen offensive action, keeping the besieger in ignorance of the dispositional dispositions of the garrison, and of what progress he is making: all these, with their influence on the morale of both sides, tend towards successful defences and do not point towards the use of armour. It may further be said that the use of armour as a general rule is unnecessary, because a concealed battery is a protected one; and with the long ranges now usual for heavy guns and howitzers, there is not generally much difficulty about concealment.

In the opinion, however, of the present writer an exception must be made for guns intended to flank the line of defence, which would generally need bomb-proof over-head cover. Further, when we leave theory and come to the consideration of actual problems of defence, it will often be found that it is necessary to place guns in certain positions where good concealment cannot be got. In such cases some form of protection must be given if the guns are to engage the concealed batteries of the attack.

III. THE ATTACK OF FORTRESSES

In considering the history of siegcraft since the introduction of gunpowder, there are three main lines of development to follow, viz. the gradually increasing power of artillery, the systematizing of the works of attack, and in recent times the change that has been brought about by the effect of modern small-arm fire.

Cannon appear to have been first used in sieges as mortars, to destroy hoardings by throwing round stones and barrels of burning composition. Early in the 15th century we find cannon throwing metal balls, not only against hoarding and battlement, but also to breach the bases of the walls. It was only possible to work the guns very slowly, and archers or crossbowmen were needed in support of them, to drive the defenders from the crenellations or loopholes of the battlements. At that period the artillerists were in place of the medieval siege engines and in much the same manner. The guns of the defence were inaccurate, and being placed high on the walls were made ineffective by bad mountings, which did not allow of proper depression. The besieger therefore could place his guns close to the walls, with only the protection of a few large gabions filled with earth, set up on the ground on either side of the muzzle.

In the course of the 15th century the power of artillery was largely increased, so that walls and gates were destroyed by it in an astonishingly short time. Three results shortly followed.
The guns of the defence having gained equally in effectiveness, greater protection was needed for the attack batteries; bastions and outworks were introduced to keep the besieger at a distance from the inner walls; and the walls were sunk in ditches so that they could only be breached by batteries placed on the edge of the glacis.

Early in the 16th century fortresses were being rapidly remodelled on these lines, and the difficulties of the attack were at once very much increased. The tendency of the assailants was still to make for the curtain, which had always been considered the weak point; but the besiegers now found that they had to bring their guns right up to the edge of the ditch before they could make a breach, and in doing so had to pass over ground which was covered by the converging fire from the faces of the bastions. Towards the end of the century the attack of the curtain was delayed and the cross-fire over the ground in front increased by the introduction of ravelins.

The slight gabion protection for the siege batteries was at first replaced by strong timber shelters. These were found inadequate; but a still greater difficulty was that of bringing up the siege guns to their positions, emplacing them and maintaining communication with them under fire. In addition to this, the guns of the defence until they could be overpowered (a slow process) dominated a wide belt of ground in front of the fortress; and unless the besiegers could find some means of maintaining a strong guard close to their batteries these were liable to be destroyed by sorties from the covered way.

Gradually the whole problem of siege work centred round the artillery. The besiegers found that they had first to bring up enough guns to overpower those of the defence; then to advance their guns sufficiently from which they could breach the walls; and throughout these operations to protect them against sorties. Breaches once made, the assault could follow on the old lines.

The natural solution of the difficulty of approach to the battery positions was the use of trenches. The Turks were the first to make systematic use of them, having probably inherited the idea from the Eastern Empire. The soldiers of Christendom, however, strongly disliked digging, and at first great leaders like Bayard and Montluc had themselves to use pick and shovel, to give their men an example. In due course the necessity of the trenches was recognized, but the soldiers never took kindly to them, and the difficulty was dealt with in a manner reminiscent of the feudal ages, by impressing large bodies of peasantry as workmen whenever a siege was in contemplation.

Through the 16th and most of the 17th century, therefore, we find the attack being conducted by means of trenches leading to the batteries, and supported by redoubts often called "places of arms" also made by trench work. During this period the result of a siege was always doubtful. Both trenches and batteries were arranged more or less at haphazard without any definite plan; and naturally it often happened that offensive action by the besieged against the trenches would disorder the attack and at times delay it indefinitely. Fig. 64, taken from a late 17th-century print by de Fer of Paris, gives a good idea of the general practice of that day when Vauban's methods were not yet generally known.

Another weak point about the attack was that after the escarp walls had been strengthened to resist artillery fire as has been described, there was no clear idea as to how they should be breached. The usual process was merely an indiscriminate pouding from batteries established on the crest of the glacis. Thus there were cases of sieges being abandoned after they had been carried as far as the attempt to breach. It is in no way strange that this want of method should have characterized the attack for two centuries after artillery had begun to assert its power. At the outset many new ideas had to be assimilated. Guns were gradually growing in power; sieges were conducted under all sorts of conditions, sometimes against medieval castles, sometimes against various and widely differing examples of the new fortification; and the military systems of the time were not favourable to the evolution of method. It is the special feature of Vauban's practical genius for siege warfare that he introduced order into this chaos and made the issue of a siege under normal conditions, a mere matter of time, usually a very short time.

The whole of Vauban's teaching and practice cannot be condensed into the limits of this article, but special reference must be made to several points. The most important of these is his general arrangement of the attack. The ultimate object of the attack works was to make a breach for the assaulting columns. To do this it was necessary to establish breaching batteries on the crest of the glacis; and before this could be done it was necessary to overpower the enemy's artillery. This preliminary operation is nowadays called the "artillery duel." In Vauban's day the effective range of guns was 600 to 700 yds. He tells us that it was customary to establish batteries at 1000 yds. from the place, but that at that range they did little more than make a great deal of noise. The first object of the attack, therefore, after the preliminary operations of investment, &c., had been completed, was to establish batteries within 600 or 700 yds. of the place, to counter-batter or enfilade all the faces bearing on the front of attack; and to protect these batteries against sorties. After the artillery of the defences had been subdued—if it could not be absolutely silenced—it was necessary to push trenches to the front so that guns might be conveyed to the breaching positions and emplaced there in batteries. Throughout these processes it was necessary to protect the working parties and the batteries against sorties.

For this purpose Vauban devised the Places d'armes or lignes parallèles. He tells us that they were first used in 1673 at the siege of Maestricht, where he conducted the attack, and which was captured in thirteen days after the opening of the trenches. The object of these parallels was to provide successive positions for the guard of the trenches, where they could be at hand to repel sorties. The latter were most commonly directed against the trenches and batteries, to destroy them and drive out the working parties. The most vulnerable points were the heads of the approach trenches. It was necessary, therefore, that the guard of the trenches should be in a position to reach the heads of the approaches more quickly than the besieged could do so from the covered way. This was provided for as follows.

The first parallel was usually established at about 600 yds. from the place, this being considered the limiting range of action.
of a sortie. The parallel was a trench 12 to 15 ft. wide and 3 ft. deep, the excavated earth being thrown forward to make a parapet 3 or 4 ft. high. In front of the first parallel and close to it were placed the batteries of the "first artillery position."

While these batteries were engaged in silencing the enemy's artillery, for which purpose most of them were placed in prolongation of the faces of the fortress so as to enfilade them, the "Approach Trenches" were being pushed forward. The normal attack included a couple of bastions and the ravelin between, with such faces of the fortress as could support them; and the approach trenches (usually three sets) were directed on the capitals of the bastions and ravelin, advancing in a zigzag so arranged that the prolongations of the trenches always fell clear of the fortress and could not be enfiladed.

Fig. 65, taken from Vauban's *Attack and Defence of Places*, shows clearly the arrangement of trenches and batteries.

After the approach trenches had been carried forward nearly half-way to the most advanced points of the covered way, the "second parallel" was constructed, and again the approach trenches were pushed forward. Midway between the second parallel and the covered way, short branches called *Demi-parallels* were thrown out to either flank of the attacks: and finally at the foot of the glacis came the third parallel. Thus there was always a secure position for a sufficient guard of the trenches. Upon an alarm the working parties could fall back and the guard would advance.

Trenches were either made by *common trenchwork*, *flying trenchwork* or *sap*. In the first two a considerable length of trench was excavated at one time by a large working party extended along the trench: flying trenchwork (formerly known as *flying sap*) being distinguished from common trenchwork by the use of gabions, by the help of which protection could be more quickly obtained. Both these kinds of trenchwork were commenced at night, the position of the trench having been previously marked out by tape. The "tasks" or quantities of earth to be excavated by each man were

so calculated that by daybreak the trench would afford a fair amount of cover. Flying trenchwork was generally used for the 2nd parallel and its approaches, and as far beyond it as possible. In proportion as the attack drew nearer to the covered way, the fire of the defenders' small-arms and wall-pieces naturally grew more effective, though by this time most of their artillery would have been disembowelled by the fire of the siege batteries. It therefore became necessary before reaching the 3rd parallel to have recourse to *sapping*.

Sapping required trained men. It consisted in gradually pushing forward the end of a narrow trench in the desired direction. At the sap-head was a squad of sappers. The leading man excavated a trench 1 ft. 6 in. wide and deep. To protect the head of the trench he had a shield on wheels, under cover of which he placed the gabions in position one after another as the sap-head progressed. Other men following strengthened the parapet with fascines, and increased the trench to a depth of 3 ft., and a width of 2 ft. 6 in. to 3 ft. Fig. 66, taken from Vauban's treatise on the attack, shows the process clearly. The sap after being completed to this extent could be widened at leisure to ordinary trench dimensions by infantry working parties.

As the work at the sap-head was very dangerous, Vauban encouraged his sappers by paying them on the spot at 60 francs per day, increased rapidly in proportion to the risk. He thus stimulated all concerned to do their best, and reckoned that under average conditions he could depend on a rate of progress for an ordinary sap of about 50 yds. in 24 hours.

It is interesting to compare the more recent method of sapping with that above described (fig. 67 taken from the *Instruction in Military Engineering*, 1868). It is no longer possible to place gabions in position at the sap-head under fire. Accordingly the leading sapper excavates to the full depth of 4 ft. 6 in., and the rate of progress is retarded proportionately, so that an advance of only 15 to 30 yds. in 24 hours can be reckoned on instead of 50. The head of the sap is protected by a number of half-filled sandbags, which the leading sapper throws forward as he goes on.

The nearer the approaches drew to the covered way, the more oblique became the zigzags, so that little forward progress was made in proportion to the length of the trench. The approaches were then carried straight to the front, by means of the "double sap," which consisted of two single saps worked together with a parapet on each side (fig. 68). To protect these from being enfiladed from the front, traverses had to be left at intervals, usually by turning the two saps at right angles to right or left for a few feet, then forward, and so on as shown in fig. 69, the distance apart of these traverses being of course regulated by the height from which the enemy's fire commanded the trench.

The later stages in the attack are illustrated in fig. 70. From the third parallel the attack was pushed forward up the glacis by means of the double sap. It was then pushed right and left along the glacis, a little distance from the crest of the covered way. This was called "crowning" the covered way,
and on the position thus gained breaching batteries were established in full view of the escarp. While the escarp was being breached, if it was intended to use a systematic attack throughout, a mine gallery (see Mining below) was driven under the covered way and an opening made through the counterscarp into the ditch. The sap was then pushed across the ditch, and if necessary up the breach, the defenders' resistance being kept under by musketry and artillery fire from the covered way. The ravelin and bastions were thus captured successively, and where the bastions had been re-trenched the same methods were used against the retrenchments.

Vauban showed how to breach the escarp with the least expenditure of ammunition. This was done by making, with successive shots placed close together (which was feasible even in those days from a position so close as the crest of the covered way) horizontal and vertical cuts through the revetment wall. The portion of revetment enclosed by the cuts being thus detached from support was overthrown by the pressure of the earth from the rampart. Ricocet fire was also the invention of Vauban. He showed how, in enfilading the face of a work, by using greatly reduced charges a shot could be made to drop over the crest of the parapet and skim along the terreplein, dis-mounting guns and killing men as it went.

The constant success of Vauban must be ascribed to method and thorough organization. There was a deadly certainty about his system that gave rise to the saying "Place assiégé, place prise." He left nothing to chance, and preferred as a rule the slow and certain progress of saps across the ditch and up the breach to the loss and delay that might follow an unsuccessful assault. His contemporary and nearest rival Coehoon tried to shorten sieges by heavy artillery fire and attacks across the open; but in the long run his sieges were slower than Vauban's.

So much a matter of form did the attack become under these conditions, that in comparing the supposed defensive powers of different systems of fortification it was usual to calculate the number of days that would be required in each case before the breach was opened, the time being measured by the number of hours of work required for the construction of the various trenches and batteries. It began to be taken as a matter of course that no place under any circumstances could hold out more than a given number of days; and naturally, when the whole question had become one of formula, it is not surprising to find that places were very often surrendered without more than a perfunctory show of resistance.

The theory of defence at this time appeared to be that since it was impossible to arrest the now methodical and protected progress of the besiegers' trenches, no real resistance was possible until after they had reached the covered way, and this idea is at the root of the extraordinary complications of outworks and multiplied lines of ramparts that characterized the "systems" of this period. No doubt if a successor to Vauban could have brought the same genius to bear on the actual defence of places as he did on the attack, he would have discovered that the essence of successful defence lay in offensive action outside the body of the place, viz. with trench against trench. For want of such a man the engineers of the defence resigned themselves contentedly to the loss of the open ground outside their walls, and relied either upon successive permanent lines of defence, or if these did not exist, upon extemporized retrenchments, usually at the gorge of the bastion.

It is curious that such experienced soldiers as most of them were should not have realized the fatal effect upon the minds of the defenders which this almost passive abandonment of line after line must needs produce. Even a civilian—Machiavelli—had seen into the truth of the matter years before, when he said (Treatise on the Art of War, Book vii.): "And here I ought to give an advice... to those who are constructing a fortress, and that is, not to establish within its circuit fortifications which may serve as a retreat to troops who have been driven back from the first line... I maintain that there is no greater danger for a fortress than rear fortifications whither troops can retire in case of a reverse; for once the soldier knows that he has a secure retreat after he has abandoned the first post, he does in fact abandon it and so causes the loss of the entire fortress."

It must, however, be remembered that in those days when soldiers were mostly of a separate or professional caste, the whole thing had become a matter of business. Fighting was so much regulated by the laws and customs of war that men thought nothing of giving up a place if, according to accepted opinion, the enemy had advanced so far that they could no longer hope to defend it successfully. Once this idea had set in it became hopeless to expect successful defences, save now and then when some officer of very unusual resolution was in command. This is the real reason for the feeble resistance so often offered by fortresses in the 17th and 18th centuries, which has been attributed to inherent weakness in fortifications.

Custom exacted that a commandant should not give up a place until there was an open breach or, perhaps, until he had stood at least one assault. Even Napoleon recognized this limitation of the powers of the defence when in the later years of his reign he was trying to impress upon his governors the importance of their charge. The limitation was perfectly unnecessary, for history at that time could have afforded plenty of instances of places that had been successfully defended for many months after breaches were opened, and assault after assault repulsed on the same breach. But the same soldiers of the 17th and 18th centuries who had created this artificial condition of affairs,
established it by making it an understood thing that a garrison which surrendered without giving too much trouble after a breach had been opened should have honourable consideration; while if they put the besiegers to the pains of storming the breach, they were liable to be put to the sword.

It has been necessary to dwell at some length on the siegecraft of Vauban and his time, not merely for its historical interest, but because the system he introduced was practically unaltered until the end of the 19th century. The sieges of the Peninsular War were conducted on his lines; so was that of Antwerp in 1830; and as far as the disposition of siege trenches was concerned, the same system remained in the Crimea, the Franco-German War and the Russo-Turkish War. The sieges in the Napoleonic wars were few, except in the Iberian peninsula. These last differed from those of the Vauban period and the 18th century in this, that instead of being deliberately undertaken with ample means, against fortresses that answered to the requirements of the time, they were attempted with inadequate forces and materials, against out-of-date works. The fortresses that Wellington besieged in Spain had rudimentary outworks, and escarpments that could be seen and breached from a distance. At that time, though the power of small arms had increased very slightly since the last century, there had been a distinct improvement in artillery, so that it was possible to breach a visible revetment at ranges from 500 to 1000 yds. Wellington was very badly off for engineers, siege artillery and material. Trench works could only be carried out on a small scale and slowly. Time being usually of great importance, as in the first two sieges of Badajoz, his technical advisers endeavoured to shorten sieges by breaching the escarpment from a distance—a new departure—and launching assaults from trenches that had not reached the covered way. Under these circumstances the direct attacks on breaches failed several times, with great loss of life. Wellington in one or two earlier despatches reflected on his engineers for not establishing their batteries on the crest of the cliffs. The failures are, however, clearly due to attempts to push sieges to a conclusion without proper preparation.

So much has been written of late years in criticism of the fortification to what may be called the Vauban period that it is important to note what were the preparations considered necessary for a siege of going out to meet the besieger, with counter trench and counter mine. This lesson has increased in value for us in proportion to the increased power of the rifle.

In comparing the resistance made behind the earthworks of Sevastopol with the recorded defences of permanent works, it is essential to remember that the conditions there were quite abnormal. Sir John Jones has told us what the relative forces of besiegers and besieged should be, and the necessary preponderance of artillery force to make the defences a failure. The following is his advice:

"The siege corps should be sufficiently strong—(1) To invest the fortress completely, and maintain the investment against all the efforts of the garrison. (2) If a regular siege is contemplated, to execute and guard all the siege works required for it. Complete investment may sometimes be impossible, but experience has repeatedly shown that the difficulties of a siege are enormously increased if the garrison are able to draw fresh troops and supplies from outside, and to rid themselves of their sick and wounded," (Lewis). Again as regards artillery: "In a regular attack, where every point is gained inch by inch, it is impossible to succeed without overwhelming the defensive artillery;" and "It is useless to attempt to sap near a place till its artillery fire is subdued ..." (Jones).

These conditions were so far from being fulfilled at Sevastopol that (a) there was no investment—in fact the Russians came nearer to besieging the Allies; (b) the Russians had in guns almost throughout; (c) the Russian force in and about Sevastopol was numerically superior to that of the Allies. We must add to this that Toulcbeben had been able to get rid of most of his
FORTIFICATION AND SIEGECRAFT

[ATTACK]

would be greater than ever when the field works were backed by permanent works, good communications and the resources of a fortress. One thing was obvious—namely, that as long as the artillery of the place, of even the smallest calibres, remained unsubdued, the difficulty of trenchwork and sapping would be enormously increased, and no one seemed to have formed a clear conception of how that difficulty was to be met. A lecture delivered in Germany about 1890 is worth quoting as a fair example of the vagueness of idea then prevailing: "For the attack, the following is the actual procedure: Accumulation and preparation of material for attack before the fortress: advance of attacking artillery, covered by infantry. Artillery duel. Throwing forward of infantry: destruction of the capability for defence of the position attacked; when possible by long-range artillery fire, otherwise by the aid of the engineers. Occupation of the defensive position. Assault on the inner lines of the fortress." That seemed quite a simple prescription, but the necessary drugs were wanting. And even since Port Arthur great uncertainty as to the future of the attack remains.

Modern artillery has much simplified the construction of siege batteries. Formerly siege batteries and rampion batteries opposed each other with direct fire at ranges not too long for the unaided human eye, and the shells, travelling with low velocity, hit into the parapets, and, exploding, produced their full effect. Accordingly the task of the gunners was, by accurate fire, to destroy the parapets and embrasures and to disconnect the guns. The parapets of siege batteries were therefore made from 18 to 30 ft. thick, and the construction of such batteries, with traverses, &c., involved much work. The height of parapet necessary for proper protection being 7 ft. 6 in. to 8 ft., a great deal of labour could be saved by sinking the gun-platforms about 4 ft. below the surface level, but of course this was only possible where rock or water were not near the surface.

The effect of modern projectiles was to reduce the thickness of earth necessary for parapets. High velocity projectiles are very easily deflected upwards by even a slight bank of earth. This is
especially the case with sand. Loose earth is better than compacted earth, and clay offers the least resistance to penetration. These facts were taken note of in England more than on the Continent in the design of instructional siege batteries.

The sieges of the modern period may be further vastly simplified by the long ranges at which artillery will fight in future. It will as a rule be possible to place howitzer batteries in such positions that even from balloons it will be difficult to locate them, and even the heaviest guns may be screened from observation. This renders parapets unnecessary, and probably no more protection will be used than light splinter-proof screens to stop shrapnel bullets or fragments of concrete shells. Moreover batteries can be constructed at leisure and by daylight.

The most important point about the modern battery is the gun platform for the larger natures of guns and howitzers. These require very large and strongly built platforms in the form of detached and always an extended and deep drainage system. It would not for many years, the French practice of using high front lines, but in Russia the practice was abandoned. The engagement at Port Arthur, however, at Port Arthur made concrete platforms for 11-inch howitzers. It may be remarked that difficulties which loom largely in peace are often overcome easily enough under the stress of war.

Another gain to the attack is in connection with magazines. The old powder magazines were particularly dangerous adjuncts to batteries, and had to be very carefully bomb-proofed. Such propellants as cordite, however, are comparatively safe.

The question of magazine location is of more importance than it has ever been. Leaving out of the question the bringing up of supplies from the base of operations, the task of distribution at the front is a very large one. The Paris siege manoeuvres of 1894 furnished an actual test on this point. It was at Maex, 10 m. from the 1st artillery position, and the average distance from the 1st artillery position to the principal fort attacked was 5000 yds. The conclusion was that 150 batteries covered 10,000 yds. There were 24 batteries in the 1st artillery position; say 100 guns, spread over a front of 4000 yds. To connect Meaux with the front, the French laid some 30 m. of narrow-gauge railway largely along existing roads, single, with numerous branches and sidings. They ran 11 regular trains to the front daily and half-a-dozen supplementary. The amount of artillery material sent up was over 5000 tons, without and 100 vessels would require a little time. They were also made on transport for other purposes. For instance, one complete bakery train was sent up daily. The amount of ammunition sent up would be limited only by the power of transporting it. A siege train of 100 pieces could probably dispose of from 300 to 1000 tons of ammunition a day, at the maximum rate of firing.

But the most important question affecting the sieges of the future (putting aside accidental circumstances) will be the communication of the ground. Assuming that local conditions do not specially favour the artillery of either side, it is highly probable that the artillery duel will result in a deadlock. If it can be shewn that there is an advisability of the defence from the 1st or distant artillery position (which, whether they are in cupolas or in concealed positions, will in any case be an extremely difficult task), it will be necessary for the besieging forces to fix on points of intersection for those that offer better positions for fire and observation. In doing this they will have to face the defenders' infantry, entrenched, backed by their unsilenced guns, and having secure places of assembly from which to deliver counter-attacks. The distance to which they can work forward and establish themselves under these conditions will depend on the ground. It will then be for the engineers to cross the remaining space by sap. This, under present conditions, will be a tedious process, and may even take long enough to cause the failure of the siege.

As to the manner of the sap, it will certainly be "deep," as long as the length of the artillery position. When the 4 ft. 6 in. sap already described was first introduced, it was known as a "deep sap"; but the sieges of the future will probably necessitate a true deep sap, that is one in which the whole of the necessary cover is got below the level of the earth.

Such a sap may consist of an open trench, about 6 ft. deep, the whole of the excavated earth being carried away through the trench to the rear; or a blinded trench, covered in as it progresses by splinter-proof timbers and earth; or a tunnelled trench, leaving a foot or so of surface earth undisturbed. In either case nothing should be visible from the front to attract artillery fire. As the sap is constructed it may be used as a temporary magazine, in places, to give command over the foreground for the rifles of the guard of the trenches.

The third sap will have to be pushed up quite close to the defenders' trenches and obstacles. After that further progress must either be made by mining, or as seems very probable, by getting the better of the defenders in a contest with shells from short-range mortars. The latter is a comparatively easy business which lent itself to the defensive methods of the time, so in the future the detached forts and supporting points in the girdle of a fortress will be sited where smooth and gentle slopes of ground give the utmost opportunity to the defenders' fire, and the least chance of concealment to the enemy. There will be considerable space left free between them, and they will be at the same altitude as when the existence of a precipitous hill was the raison d'être of the castle. In some places, as at Port Arthur, the whole country-side may be reason of its steep and broken slopes be covered to the point of making assault through every point from difficulties to account. But wherever it is possible the defender will provide for a space of 1000 yds. or so, swept by fire and illuminated in front of his lines. That space will have to be crossed by sap, and even the imagination to realize how great the task will be for the besieger.

There are other modern methods of siege warfare to be noticed, but the most important, which is the effective use of balloons; but the use of these in war is unlikely to correspond to peace expectations. They must be kept at a considerable distance from the enemy's guns, a distance which will increase as the war goes on; besides, they cannot be shot down, they can observe usefuly is limited, so is the observers' power to search out hidden objects behind vertical screens. Thus, suppose a captive balloon at a height of 2000 ft., and distance 400 yds. from an enemy's howitzer battery: and suppose the battery placed behind a steep hill-side or a grove of trees, at such a distance that a shell fired with 30° elevation can just clear this screen. The line of sight from the observer to the battery is inclined to the horizontal at 3°, but this is, or roughly 10°. It is obvious, therefore, that the observer cannot see the battery.

It is also possible that the balloon may be used to assist the batteries by marking the effects of their fire. For this to be done on any practical scale a balloon would be required for each battery: that is, for 100 guns, some 20 or 25 balloons. These would require an equal number of balloonists and their officers. The movement of such a balloon would depend upon the weather, and the work of observation would not be possible, except for a very short time of the day.

Telephones and all other means of transmitting intelligence rapidly are now of the utmost importance to both attack and defence. Maps marked with numbered squares are necessary for directing artillery fire; and the organization in every branch will have to be better results than ever before, and the question of communication and transport from the base of supplies right up to the front needs detailed study, in view of the great weight of ammunition and supplies which will have to be transported. The use of light mortars for the trenches, introduced by Cochoomo and revived with exasperated means at Port Arthur, needs great attention. It may be prophesied that the issue of siege batteries in the future, when skillfully conducted on both sides with sufficient resources, will depend mainly on the energy of the defenders in trench work, on mining and countermining in connexion with the trenches, and on the use of light mortars made to throw large charges of high explosive for short distances with great accuracy.

For a brief narrative of the siege of Port Arthur in 1904, one of the most celebrated of modern sieges as regards its epic interest, and its military importance, the reader is referred to the article Russo-Japanese War.

DEFINITIONS.—The following definitions may be useful, but have no connection with the evolution of the attack, to which this section is mainly devoted.

Investigation.—This most necessary, almost indispensable operation of every siege consists in surrounding the fortress about to be besieged, so as to cut off its communications with the outside world. Preliminary investment which is carried out by cavalry and light troops before the arrival of the besieging force, consists in closing the roads as to to put out batteries and reinforcements. Close investment should be of such a character as to prevent any sort of communication, even by single messengers or spies. The term "blockade" is sometimes loosely used instead of investment.

Contravallation.—The term "circumvalation" or "contravallation" of Circassia, was a place of importance in the history of the event. "Contravallation" was a line of parapet which the besieger made outside the investing position, in his own front line, to resist a direct attack by a relieving army. The line of contravallation was the line of parapet and trench sometimes made by the besieger all round the town he was attacking, to check the sorties of the garrison.

Observeing Force.—When circumstances make the reduction of a particular fortress in the theatre of operations unnecessary a force is often detached to "observe" it. The duty of this force will be to watch the garrison and prevent any hostile action such as raids or cutting off communications. It is also armed with a heavy artillery battery.

Bombardment.—This operation, common to all ages, consists in a general (sometimes an indiscriminate) fire against either the whole rounds of shell, or a part covered by the attack. In ancient and medieval times the effect of a bombardment—whether of ordinary missiles, of incendiary projectiles, or of poisonous matters tending to breed pestilence—upon a population closely crowded within the walls was a fearful thing. In the modern age, however, the purpose of the bombardment is to reduce the fortress by breaking its walls down and by the damage to it which results. It is the destruction of the fortress which is aimed at; the process of bombardment is a rough and ready way of achieving this end. In the modern age it is not often practised; the efforts of the besieger are directed towards the capture of the fortress by siege rather than by the destruction of its walls by bombardment.
IV. MILITARY MINING

It has been noted already that mining is one of the most ancient resources of siege warfare. The use of gunpowder in mining operations dates from the end of the 15th century. When Shakespeare makes Fluellen say, at Henry V.'s siege of Harfleur, "th'ath'senary is digg himself four yards under the countermines; I think 'a will pow up all, if there is not better directions," he is anticipating the development of siegcraft by nearly 100 years. Pedro di Navarro, a Spanish officer, is credited with the first practical use of explosive mines. He employed them with great success at the siege of Naples in 1503; and afterwards, when rebuilding the Castello Nuovo after the siege, was probably the first to make permanent provision for their use in countermines. Countermining had been a measure of defence against the earlier methods of attack-mining; the object being to break into the besiegers' galleries and fight hard to hand for the possession of them. When the explosive mine was introduced, it became the object of the defenders to establish their countermines near the besiegers' galleries and destroy them by the effect of the explosion. In the 200 years or so that have passed this branch of warfare has changed less than any other. Methods of mining have not advanced much, and the increased power of high explosives as compared with gunpowder has its least advantage in moving masses of earth.

When a besieger has arrived by means of trenches within a certain distance of the enemy's works without having subdued their fire, he may find that the advance by sap becomes too slow and too dangerous. He can then advance underground by means of mine galleries, and by exploding large charges at the heads of these galleries can make a series of craters. These craters are then occupied by infantry, and are connected with each other and with the parallel in rear by trenches, thus forming a new parallel. If not interfered with by the defenders the besieger can advance in this way until he reaches the counterscarp. His mines will now be turned to a new purpose, viz. to breach the counterscarp and afterwards the escarp. This is done by placing suitable charges at intervals behind the scars in such a height above the foundations that the pressure of the earth above the mine will more than counterbalance the resistance of the masonry.

But if the defenders are active, they will countermine. There is as a general rule this broad difference between the mines of the defence and those of the attack, that the defenders do not wish the surface of the ground broken, lest increased opportunities of getting cover should be offered to the besiegers. The object of the defence, therefore, is to destroy the besiegers' galleries without forming craters, and for this purpose they generally endeavour to get under the attack galleries. The defenders may, however, wish, if the opportunity is allowed them, to explode mines under the attack parallels, in which case there is of course no objection to disturbing the surface.

"At the commencement of the subterranean war the main object of the defence is to force the besieger to take to mining operations as early as possible, as it is a tedious operation and will prolong the siege. Every endeavour must be made to push forward countermines so as to meet and check the attack. On the approach of the operation it is necessary to add regular intervals to suspend all work for some minutes at a time, closing doors of communication and employing experienced listeners at the heads of the countermines. This matter is a most important one, as a premature explosion of the defender's mines is a double loss to the defender, a loss of a mine and an advantage to the enemy in more than one way. As soon as the doomed mines of the besieger have been stopped heavy fire should be brought to bear on the craters, and if possible sorties should be made to prevent the enemy occupying them. At the same time every effort should be made underground to surround the galleries, and as it were isolate, the craters so as to prevent the besieger making a new advance from them. The efforts of the attack at this stage will probably be directed to the formation of what are called "Boule shafts" (i.e. shafts partially lined in which charges are hastily fired with little or no tamping) and to meet these in time the defender may resort to the use of boring tools, and so place charges somewhere in advance of the heads of the counter-

mines. His great object must be to prevent as long as possible the besieger from getting underground again; and these occasions, when the power of resistance is temporarily equal to, if not greater than, that of the attack, should be made the most of by the defence." (Lewis, Text-book of Fortification, 2nd. 1893.)

The defence has the advantage, in the case of fortresses, of being able to establish beforehand a system of countermine galleries in masonry. Many systems have been worked out for this purpose. A good typical arrangement is that of General Marescot, published in 1799, shown in fig. 72.

From Textbook of Fortification, by permission of the Controller H.M. Stationery Office.

FIG. 72.

The main galleries (those running out in a straight line from the counterscarp gallery c to three of the points a) fall gently to the front to a depth of 30 or 40 ft. below the surface—the deeper they are the less they will suffer from the enemy's mines. Branch galleries (marked b & d) run obliquely upward from them to right and to left, leading to the mines, which are placed at various depths, according to circumstances.

Two main points must be observed in any system of countermines: the branch galleries must run obliquely forward, so as not to present their sides to the action of the enemy's mines; and the distance between the ends of the branches from adjacent main galleries should be such that the enemy cannot pass between them unheard. This distance will vary with the nature of the soil, but may be taken roughly as 20 yds. A convenient size for main galleries is 6 ft. high by 3 ft. wide: branch galleries may be 5 ft. by 3 ft. When the enemy is approaching, other branch galleries, called listeners, will be pushed out from main
and branch galleries. The section to fig. 1 of fig. 72 shows openings left for the purpose.

Another use of mines in defence is in connexion with breaches. A permanent arrangement for this purpose, by General Dufour, is shown in fig. 72. Yet another use, on which much ingenuity was expended in the 18th century, is to extemporize retrenchments.

The charges of mines depend of course upon the effect which is desired. When the charge is strong enough to produce a crater, the radius of the circular opening on the surface of the ground is called the radius of the crater. The line drawn from the centre of the charge to the nearest surface, which is expressed in feet, is called the line of least resistance (L.L.R.). When a mine produces a crater the diameter of which is equal to the line of least resistance, it is called a one-lined crater; when the diameter is double the L.L.R., a two-lined crater and so on. Common mines are those which produce a two-lined crater. Over-charged mines produce craters greater than two-lined, and undercharged mines less. A camouflage does not produce a crater; it is used when the object is to destroy an enemy’s gallery without breaking the surface. Fig. 73 shows sections of the different kinds of mines, with their different kinds of mines.

**Action of a Common Mine**

**Crater Charge**

```
Crater Charge
3 lined 1077 lbs. (3-05 ft.)
4 lined 2021 lbs. (6-90 ft.)
5 lined 4174 lbs. (9-60 ft.)
6 lined 7907 lbs. (12-90 ft.)
7 lined 11589 lbs. (15-30 ft.)
```

**Probable spheroids of rupture for overcharged Mines**

**Fig. 73.—Mines.**

craters and the effect they will produce downwards and horizontally in ordinary earth.

Consideration of this figure will show that it is impossible to place a long charge at such a depth below the surface that it will destroy all galleries of the enemy within a considerable radius, without much disturbing the surface of the ground.

Bored mines, which have been alluded to above, are a comparatively recent innovation. When the enemy is heard at work in one of his galleries and his position approximately determined by the sound, it is necessary to drive a branch gallery with all speed in that direction, and when it has advanced as far as appears necessary, to load, tamp and discharge a mine before the enemy can fire his own mine. This is one of the most delicate and dangerous operations of war, and success will fail to those who are at the same time most skilful and most determined. The work can be hastened and made less dangerous as follows: Instead of driving a branch gallery, a hole several inches in diameter is bored in the required direction. With suitable tools there is no difficulty in driving a straight bore hole 30 ft. or 60 ft. long. A small charge of high explosives is then pushed up to the end of the borehole and fired. This forms a small camouflet chamber by compressing the earth around it. Into this chamber the charge for the mine is passed up the borehole. No tamping of course is required.

**Calculation of Charges.**—The quantity of powder required for a charge is expressed in lbs. in terms of L.L.R., and the following formulae are used:

\[ I = \text{L.L.R. in ft., } r = \text{radius of crater in ft., } c = \text{powder charge in pounds, } s = \text{variable dependent on the nature of the soil.} \]

For a common mine \( c = \frac{5}{10} I^2 \)

For an overcharged mine \( c = \frac{5}{10} I^2 - 9(r-1)^2 \)

For an undercharged mine \( c = \frac{5}{10} I^2 - 9(r-1)^2 \)

The values to be given to \( s \) are:

<table>
<thead>
<tr>
<th>Nature of Soil</th>

Military mining is carried on by means of vertical shafts and horizontal or inclined galleries. When the soil is very stiff, very little or even no lining is required for shafts and galleries; but usually they have to be lined either with cases or frames.

Cases make a complete lining of 2 in. planking. Frames are used at intervals of 4 or 5 ft. to support a partial lining of planks. Cases are of course preferable in other respects; but in ordinary soil they take up more timber.

There are two kinds of gallery in ordinary use in the British service, namely the common gallery whose interior dimensions with cases are 5 ft. 6 in. X 2 ft., and the branch gallery which is 4 ft. X 2 ft. The shaft has about the same dimensions as a branch gallery. Formerly it was sometimes necessary in the systematic attack of a fortress to get guns down into the ditch. For this purpose a ‘great gallery’ was used, 6 ft. 6 in. in height and 6 ft. 8 in. wide, internal dimensions.

Miners’ Tools.—These are few and simple. The pick and shovel differ from the ordinary types in having rather shorter handles suitable for working in limited space in which they are used. There is also a brush-pick, an implement with a straight handle and a pointed shovel head 6 in. long and 3 in. wide. The miner’s truck, used for drawing the earth from the end of the gallery to the bottom of the shaft, is a hollow wooden truck holding about 2 cub. ft. of earth. Formerly the noise of the wheels of the truck passing over the uneven wooden floor of the gallery was very liable to be heard by the enemy. To obviate this they now have leather tyres and should run on batters nailed to the floor. The miner’s bucket is a small canvas bucket with a couple of ropes attached, by which the earth can be drawn up the shaft. Nowadays, however, the truck itself has chains attached to it, by which it is drawn up, with the aid of a windlass, to the surface. By this method more earth can be taken up in one lift, and time and labour are not wasted in transferring the contents of the truck to the bucket.

**Ventilation** is an important point. The breath of the miners and the burning of their candles (when electric light is not available) vitiates the air in the galleries; so that even in clean ground a gallery should not be driven more than 60 ft. without providing some means of renewing the air. This is usually done by forcing fresh air, by means of a pump or bellows, through a flexible hose to the head of the gallery. Where the galleries have been fired close by there is great danger from poisonous gases filtering through the soil into the gallery. This difficulty is nowadays met by the use of special apparatus, such as helmets into which fresh air is pumped, so that the wearers can breathe the air of the outside at all times. Ventilation can also be assisted by boring holes vertically to the surface of the ground.

Where a point has been reached at which it is proposed to fire a mine, a chamber just large enough to hold the charge is cut in the
side of the gallery. The object of this is to keep the charge out of the direct line of the gallery and thus increase the force of the explosion. The charge may be placed in canvas bags, barrels or boxes, precautions being taken against damp.

The filling of the gallery is of great importance, for if the mine is not exploded with success, not only is valuable time lost, which may give the enemy his opportunity, but it will probably be necessary to dismantle the mine and re-arrange the operation attended by considerable danger.

The loading of the mine should therefore be done by the officer in charge with his own hands. He has to work in a very cramped position, sometimes in the dark, and with elementary skill. Of course no naked lights can be allowed near powder. Everything should therefore be prepared beforehand to facilitate the loading of the mine and placing of the fuze. At Chatham a 1000 ft. long mine was loaded in 30 minutes. The powder was put up the gallery by hand in sandbags, and emptied into a box of the required size.

When firing (see below) is employed, the officer who loads the mine must be careful to see that it is so arranged as to make firing certain, and that the leads passing out of the gallery are not liable to damage in the process of tamping.

Firing.—This operation consists in filling up the head of the gallery solidly, for such a distance that there shall be no possibility of the charge wasting its force along the gallery. The distance depends on the charge used and the velocity of the shot. For a charge of 3 lbs. it would extend to about 7 L.R. from the charge, when the tamping is of earth in sandbags; for a 3-lined crater, to about 2 L.R. Tamping can be improved by jamming pieces of timber into any part of the gallery or gallery, or other similar materials, before firing.

Explosives.—The old-fashioned gunpowder of the grazed black variety is still the best for most kinds of military mines. Pellet and prism powders do not give good results, presumably because their action is so slow that some of the gases of explosion can escape through the pores of the earth. High explosives, with their quick shattering and rendering effect, are little more effective than gunpowder in actually moving the materials of the earth. More can be given off much more poisonous fumes than gunpowder. Some recent high explosives, however, have been specially designed to be comparatively innocuous in this respect.

Some instructions have been given above for the calculation of charges. It will, however, simplify matters for the reader to record some actual instances of charges fired both in peace and war.

In the matter of scientific experiment we find Vauban as usual leading the way, and in the following results among others were obtained by him at Tournay in 1686 and 1696: A charge of 152 lbs. placed 13 ft. below the surface produced a crater of 13 ft. radius (a two-lined crater, or "common mine"). Galleries were destroyed at distances equal to the L.R. in both horizontal and vertical directions. Double the charge, placed at double the depth, i.e., 324 lb. with an L.R. of 27 ft. made no crater, but like the first destroyed galleries below it and on each side at distances equal to the L.R. A charge of 325 lb. with L.R. of 57 ft. made a two-lined crater and destroyed a gallery, horizontally.

Bernard Forest de Belidor, a French engineer, made many experiments at La Fère about 1732, and 20 years later, as general officer and inspector of fortifications, continued them on a large scale. His experiments were directed towards destroying an enemy's galleries at greater distances than had hitherto been supposed possible, by means of very large charges (in proportion to the L.R.) which he called "exaggerated charges". He tested them with a charge of 5400 lb. of powder placed only 15 ft. 9 in. below the surface; damaged a gallery distant 65 ft. horizontally. The radius of the crater was 15 ft.

At Frederick the Great's siege of Schweidnitz in 1762 some very large charges were exploded. One of them, of $400 lb. with an L.R. of 16 ft. 3 in., made a crater of 42 ft. 3 in. radius. Readers of Carlyle's Frederick may recall his description of the contest of the rival engineers on this occasion.

At Graudenz in 1862 (experiments) a charge of 1031 lb. of powder placed 10 ft. deep, untamped, in a vertical shaft, made a crater of 15 ft. 6 in. radius. A charge of 474 lb. of guncotton, calculated as being equivalent to the above charge of powder and placed under the same conditions, made a crater of 14 ft. radius. The absence of tamping in both cases of course placed the gunpowder at a disadvantage.

The most interesting mine ever fired was that at the siege of Petersburg in the American Civil War, in June 1864. The circumstances were all abnormal, and the technical worked in the history of fortifications (for the curious) is well worth perusal. No mining tools or materials, and no military miners were available; and one had any confidence in the success of the attempt except its originator, Lieut.-Colonel Plemont, a mining engineer by profession, his regiment which was recruited from a mining population, and General Burnside the corps commander. The opposing entrenchments were 130 yds. apart. The mine was started behind the Federal lines and driven a distance of 510 ft. till it came under the field redoubt in the Confederate lines. There two branches were made right and left, each about 38 ft. long, and in them eight mines were started. The mines were fired, but they failed, and an officer and a sergeant volunteered to enter the gallery to seek the cause of the failure. A destructive spike in two lengths of fuze was thus discovered and repaired. At the second attempt the mines were fired and with success, and made a gigantic crater 170 ft. long by 60 ft. wide and 30 ft. deep. The occupants of the redoubt, at least several hundred men (they have been stated at 1000), were blown up and mostly killed. The assault which followed, however, failed completely, for want of organization. The infantry was drawn up in readiness to advance, but no outlets had been provided from the parallel, and this and other like assumptions crushed the Southern hopes, and gave the defending artillery a moment's respite. Thus the assailants gained the crater but could not advance beyond it in face of the defenders' fire, nor could they establish themselves within it, on its steep clay sides, for want of entrenching tools. With no further prospects forward in support, but being in many cases of inferior quality, they could not be induced to go forward, and hurried in disorder in the advance overwhelmed crater. Over 1000 of the Federals were captured when the Confederates retook the crater by a counter-attack and the total loss of the Federals in the attack was nearly 4000.

The wars of the last generation have done little or nothing to advance the science of military mining, but a good deal has been done in peace to improve the means. Electric lighting and electric firing of mines will be a great help; modern drilling machines may be used to go through rock; ventilating arrangements are much improved; and the use of bored mines is sure to have great developments. The Russo-Japanese War taught us new in mines warfare, and as to the effects of mines, but the siege of Port Arthur had this moral among others; just as in future, in the frontal attack of positions, trench must oppose trench, so in fortress warfare mines will be more necessary than ever. It appears that they will be essential to destroy both the ditch-flanking arrangements of forts and the escarp or other permanent obstacle beyond the ditch.

V. FIELD FORTIFICATION

Field Fortifications, now more often spoken of as field defences, are those which are constructed at short notice, with the means locally available, usually when the enemy is near at hand. Subject to the question of time, a very high degree of strength can be given to them, if the military situation makes it worth while to expend sufficient labour. A century or more ago, the dividing line between permanent and field fortification was very rigidly drawn, since in those days a high masonry escarp surmounted by a rampart was essential to a permanent fortress, and these that were not thus enlightened. Works without masonry, in other words made as strong as possible with deep ditches and heavy timbers,—such as would require about six weeks for their construction,—were known as semi-permanent, and were used for the defence of places which acquired strategic importance in the course of a war, but were not immediately threatened. The term field fortification was reserved for works constructed of lighter materials, with parapets and ditches of only moderate development. Redoubts of this class required a fortnight at most for their construction.

In modern fortification if cupolas and deep revetted ditches were essential to permanent defences, the dividing line would be equally clear. But as has been shown, this is not universally admitted, and where the resources exist, the use of our present
means of construction, such as steel joists, railway rails, reinforced concrete and wire, in conjunction with the defensive power of modern fire-arms, makes it possible to extemporize in a very short time works having much of the resisting power of a permanent fortification. Furthermore, such works can be expanded from the smallest beginnings; and, if the site is not too exposed, in the presence of the enemy.

Field fortification offers, as regards the actual constructions, a very limited scope to the engineer; and a little consideration will show that its defensive possibilities were not greatly affected by the change from machine-thrown projectiles to those fired by rude smooth-bore guns. There is therefore nothing in the history of this branch of the subject that is worth tracing, from the earliest ages to about the end of the 18th century. One or two points only are noticed. The use of obstacles is probably one of the earliest measures of defence. Long before missile weapons had acquired such an importance as to make it worth while to seek shelter from them, it would obviously have been found desirable to have some means of checking the onrush of an enemy physically or numerically superior. Hence the use by savage tribes, to this day, of pits, pointed stakes hidden in the grass, entanglements and similar obstacles. In this direction the ages have made no change, and the most highly civilized nations still use the same obstacles on occasion.

Another use of field defences common to all ages is the protection given by rough earthworks to the enemy's lines of advance. The enemy, operating against an enemy more numerous but inferior in arms and discipline. In daylight such an enemy is not feared, but at night his numbers might be dangerous. Hence the Roman practice of making each foot-soldier carry a couple of stakes for palisades; and the simple defence of a thorn zariba used by the British for their camps in the Sudan.

Palisades and trenches, abatis and sharpened stakes have always been used. Except wire, there is practically no new material. As to methods, the laagers of the Boers are preceded by the wagons. When the Hussars were advanced by similar arrangements of British or Assyrian war chariots; and so in almost every direction it will be found that the expedient of to-day has had its forerunners in those of the countless yesterdays. The only really marked change in the arrangements of field defences has been caused not by gunpowder but by quick-firing rifled weapons. For that reason it is worth while to consider briefly what were the principles of field fortification at the end of the 18th century. That period has been chosen because it gives us the result of a couple of centuries of constant fighting between the disciplined and armed forces of the field armies. The field defences of the 19th century are transitional in character. Based mainly on the old methods, they show only faint attempts at adaptation to new conditions, and it was not till the end of the century that the methods now accepted began to take shape.

The essential elements of fieldworks up to the time of the Peninsular War were command and obstacle; now they are protection and concealment.

The command and obstacle were as necessary in the days of smooth-bore muskets and guns as in those of javelins and slings. With the Hussars could get close up to a work without serious loss, and attack in close order, the defenders needed a really good obstacle in front of them. Moreover, since they could not rely on their fire alone to repulse the attack, they needed a two-deep line, with reserves close at hand, to meet it with the "arme blanche." For this purpose a parapet 7 or 8 ft. high, with a steep slope, perhaps palisaded, up which the attackers must climb after passing the obstacle, was excellent. The defenders after firing their last volley could use their bayonets from the top of the parapet with the advantage of position. The high parapet had also the advantage that the attackers could not tell what was going on inside the redoubt, and the defenders were sheltered from their fire as well from view until the last moment.

The strength of a fortified line in the 18th century depended principally on its redoubts. Lines of shelter trenches had little power of defence at the time, unless they held practically as many men as would have sufficed to fight in the open. Obstacles on the other hand had a greater value, against the inelastic tactics of the time, than they have now. A good position therefore in a parapet which offered good fire-positions for field guns and plenty of facilities for creating obstacles. Strong redoubts which could resist determined assaults; good obstacles in the intervals, guns in the redoubts to sweep the intervals, and troops in formed bodies kept in reserve for counter-strokes—these were the essentials in the days of the smooth-bore.

The redoubts were liable to a heavy cannonade by field-guns before the attack. To withstand this, the parapets had to be made of a suitable thickness—from 4 or 5 ft. upwards—according to the time available, the resisting nature of the soil, and the severity of the bombardment expected.

The whole of the earth for the parapet was as a rule obtained from the ditch, in order to make as much as possible of this obstacle. The garrison in all parts of the interior of the redoubt were to be sheltered, if possible, from the enemy's fire, and with this object great pains were bestowed on the principle of "defilade." The object of defilade, which was a great fetish in theoretical works, was so to arrange the height of the parapet with reference to the terreplein of a work that a straight line (not, be it observed, the trajectory of the projectiles) passing from the muzzle of a musket or gun on the most commanding point of the enemy's position, would cut the parapet after it had been advanced forward. If this were clear and the ground did not exceed the head of a defender standing in any part of the work. This problem of defilade became quite out of date after the development of time shrapsnel, but was nevertheless taught with great rigour till within the last twenty years.

The sectional area of the ditch was calculated so that with an addition of about 10% for expansion it would equal that of the parapet. If a wider and deeper ditch was considered necessary, the surplus earth could be used to form a glacis.

The interior of the redoubt had to afford sufficient space to allow it, with these obstacles that the garrison might develop better tactics and fire-positions. The earthworks on the plateau, which had been sometimes a matter of some difficulty if a small irregularly shaped work had to contain a strong garrison. Consideration of the plan and sections of these works will show that the banquette for infantry with its slopes, and the gun platforms, took off a good deal from the interior space within the crest-line. Guns were usually placed at the salients, where they could get the widest field of fire. They were sometimes placed on the ground level, firing through embrasures in the parapet, and sometimes on platforms so as to fire over the parapet (en barbette).

In the same way as for fortresses, immense pains were taken to elaborate theoretically the traces of works. A distinction was made between forts and redoubts, the former being those which were arranged to flank their own ditches, while the redoubts did not. Redoubts again were classed as "closed," those which had an equally strong defence all round; and "half-closed," those which had on a small or timber stockade for the gorge or rear faces. Open works (those which had no gorge defence) were named according to their trace, as redans and lunettes. A redan is a work with two faces making a salient angle. It was frequently used in connexion with straight lines of trench or breastwork. A lunette is a work with two faces, usually forming an obtuse angle, and two flanks.

The forts described in the text-books, as might be expected, were designed with great ingenuity, with bastioned or demi-bastioned fronts, star traces, and so forth, and in the same books intricate calculations were entered into to balance the remblai and déblai, that is, the amount of earth in the parapets with that excavated from the ditches. In practice such niceties of course disappeared, though occasionally when the ground allowed of it star forts and bastioned fronts were employed.

On irregular ground the first necessity was to fit the redoubt to the ground on which it stood, so as to sweep the whole of the foreground, and this was generally a sufficiently difficult matter without adding the complications of flanking defences. Sir John Jones, speaking of the traces of the several works in the Torres Vedras lines, says:
FORTIFICATION AND SIEGECRAFT [FIELD FORTIFICATION]

"The redoubts were made of every capacity, from that of fig. 74 a, limited by want of space on the ground it occupied to 50 men and two pieces of artillery, to that of fig. 74 b, for 500 men and six pieces of artillery. The importance of the object to be attained being the only guide in forming the dimensions. Many of the redoubts first thrown up, even some of the smallest, were shaped like stars, under the idea of procuring a flank defence for the ditches; but this construction was latterly rejected, it being found to cut up the interior space, and to be almost fallacious with respect to flank defence, the breadth of the exterior slopes being in some cases equal to the whole length of the flanks so obtained. Even when, from the greater size of the work, some flanking fire was thus gained, the angle formed by the faces was generally so obtuse that it demanded more coldness in the defenders than ought reasonably to be expected to aim along the ditch of the opposite face: and further, this construction prevented the fire of the work being more powerful in front than in rear.

In order to decide on the proper trace of a work, it is necessary to consider whether its object be to prevent an enemy establishing himself on the ground on which it is to be placed, or whether it be to insure a heavy fire of artillery on some other point in its vicinity. In the first case every consideration should be sacrificed to that of adding to its powers of self-defence by flanks or other expedients. In the second, its powers of resistance are secondary to the establishment of a powerful offensive fire and its trace cannot be too simple. Latterly, the shape of the redoubts was invariably that most fitted to the ground, or such as best carried the enfilade fire or musketry plunge of neighbouring heights, care being taken to present the front of fire deemed necessary towards the pass, or other object to be guarded; and such will generally be found the best rule of proceeding.

This recommendation, however, is not intended to apply to isolated works of large dimensions, and more particularly to those considered the key of any position. No labour or expense should be spared to render such works capable of resisting the most furious assaults, either by breaking the parapet into flanks, or forming a flank defence in the ditch; for the experience gained in the Peninsula shows that an unflankd work of even more than an ordinary field profile, if skilfully and determinedly assaulted, will generally be carried. Nor does the serious evil of curtailing the interior space, which renders breaks in the outline so objectionable in small works, apply to works of large dimensions. Under this view the great work on Monte Agraca (fig. 75) must be considered as very defective, the flank defence being confined to an occasional break of a few feet in the trace, caused by a change of direction in the contour of the height, whilst the interior space is more than doubly sufficient for the number of its allotted garrison to encamp.

Interior and other defences. This work, however, had some of its salient points cut off by earthen lines of parapet, steeply revetted externally, and so traced as to serve for traverses to the interior. It had also three or four small enclosed posts formed within it; and the work at Torres Vedras (fig. 76) had each of its salient points formed into an independent post. These interior defences and retrenchments were intended to guard against a general panic amongst the garrison, which would necessarily be composed in part of indifferent troops, and also to prevent the loss of the work by the entry of the assailants at any weak or ill-fortified point. Such interior lines to rally on are absolutely essential to the security of a large field-work. They serve as substitutes for a blockhouse or tower, placed in the interior of all well-constructed permanent earthen works, and merit far more attention than they generally receive.

The small circular windmills of stone, which were frequently found occupying salient knolls readily converted into admirable interior posts of that nature. The profile of the several works varied on every face and flank, according to its liability to be attacked or cannonaded; the only general rule enforced being that all ditches should be at least 15 ft. wide at top and 10 ft. in depth, and the crest of the parapet have at least 8 ft. command over the crest of the countercarp. No parapet exceeded 10 ft. in thickness, unless exposed to be severely cannonaded, and few more than 6 or 8 ft.; and some, on high knolls, where artillery could not by any possibility be brought against them, were made of stone or rubble less than 2 ft. in thickness, to gain more interior space, and allow full liberty for the use of the defenders' bayonets.

Fig. 76 gives two typical sections of these works.

The works of Torres Vedras have been chosen for illustration because they offer very good historical examples, and also because of the value of the critical remarks of Sir John Jones, who as a captain was the engineer in charge of their construction. At the same time it must be remembered that they differ from ordinary field-works in having an unusual degree of strength, plenty of time and civilian labour having been available for their construction. In this respect they approximate more to semi-permanent works, the main reason why they did not receive under the circumstances a greater development of ditch and parapet being that in addition to the large number of works required, much labour was expended in abatis, inundations, scarping hill-sides and constructing roads.

Some further remarks of Sir John on the situations of the works are very instructive:

"Many of the redoubts were placed on very elevated situations on the summit of steep hills, which gave them a most imposing..."
appearance; but it was in reality a defect ... for the fire of their artillery on the object to be guarded became so plunging as to lose half its powers; the musketry could not be made to scour the face of the work, &c. and during the night both arms became of most uncertain effect.

"The dominating situation of the redoubts, however, gave confidence to the young troops which composed their garrisons, protected them from a cannonade, and screened their interior from musketry, unless fired at a high angle, and consequently at random. These considerations perhaps justify the unusually elevated sites selected for most of the redoubts on the lines, though they cannot induce an approval of them as a general measure."

The chief principle of the period was thus that the redoubts were the most important features of lines of defence, and that they combined physical obstacle and protection with good musketry and artillery positions. The value of concealment was not ignored, but it was as a rule subordinated to other considerations.

The principles of this time remained unaltered until after the Crimean War. In the American Civil War the power of the rifle began to assert itself, and it was found that a simple breastwork defended by a double rank of men could protect itself by its fire against an ordinary assault. This power of the rifle gave greatly enhanced importance to any defences that could be hastily extemporized behind walls, hedges or any natural cover. About the period of the Franco-German War other considerations came in. The increased velocity of artillery projectiles reduced in some ways their destructive effects against earth parapets, because the shell had an increasing tendency to deflect upwards on striking a bank of loose earth. Also the use of shrapnel made it impossible for troops to find cover in the terrepin of a work some distance behind the parapet.

These considerations, however, were not fully realized at that time. The reason was partly a want of touch between the engineers and the non-technical branches of most armies, and partly that original writers from the Napoleonic wars to the present day have been more occupied with the primary question of the value of field defences as a matter of tactics than with their details considered from the standpoint of fortification. There was also an influential school of writers who declared against all defences, as being injurious to the offensive spirit so essential to success. Those writers who treated of the arrangements of defences devoted themselves to theoretical details of trace quite after the old style; discussing the size and shape of typical redoubts, their distance apart and relation to lines of trenches, &c. The profiles—the thick parapet with command of 7 ft. or more, the deep ditch, and the inadequate cover behind the parapet—remained as they had been for a century.

The American Civil War showed the power of rifles behind slight defences. A parapet in 1866 is as formidable to-day as it was in the beginning of the century. It protected the great resisting power of extemporized lines; but more than that, we begin to find new arrangements for protection against shell fire (see plans and sections in Green's The Russian Army and its Campaign in Turkey). The trace of the works and the sections of parapet and ditch suggest Torres Vedras; but a multiplication of interior traverses and splinter-proof shelters show the necessity for a different class of protection. The parapet was designed according to the old type, for want of a better; the traverses and shelters were added later, to meet the necessities of the case. The Turks also used two or three tiers of musketry fire, as for instance one from the crest of the glacis, one from the parapet, and one from a traverse in rear of it. This, however, is a development which will not be necessary in future, thanks to magazine rifles.

From 1877 to 1899 the efficiency of rifles and guns rapidly increased, and certain new principles, causing the field defences of the present day to differ radically from those of the 18th century, remained to be developed. These may be considered under the following heads: the principle of penetration required, the diminished need of obstacle, and the adaptation of works to ground.

The principle that thickness of parapet is no longer required, to resist artillery fire, was first laid down at Chatham in 1896. The distance at which guns now engage makes direct hits on parapets comparatively rare. Further, a shell striking near the crest of a parapet may perhaps kill one man if he is in the way, and displace a bushel of earth. That is nothing. It is the contents of the shell, whether shrapnel or explosive, that is the source of danger and not the shell itself. Thus the enemy's object is to burst his common shell immediately behind the parapet, or his shrapnel a short distance in front of it, in order to get searching effect. If it follows that a parapet is thick enough if it suffices to stop rifle bullets, since the same thickness will a forijor keep out shrapnel bullets or splinters of shell. For this purpose 3 ft. is enough.

Real protection is gained by a trench close in rear of the parapet, deep enough to give shelter from high angle shrapnel, and narrow enough to minimize the chance of a common shell dropping into it. This protection is increased by frequent traverses across the trench.

The most essential point of all is concealment. In gaining this we say good-bye finally to the old type of work. Protection is now given by the trench rather than the parapet; command and the ditch-obstacle (which furnished the earth for the high parapet) are alike unnecessary. Concealment can therefore be studied by keeping the parapet down to the lowest level above the surface from which the foreground can be seen. This may be 18 in. or less.

The need of obstacle, in daylight and when the defenders are not abnormally few, has practically disappeared. For night work, or when the assailant is so strong as to be able to force home his attack in face of protected rifle fire, what is needed is not a deep ditch immediately in front of the parapet, difficult to climb, but also difficult to flank, but an obstacle that will detain him under fire at short range. It may be an entanglement, an abatis, an inundation: anything that will check the rush and make him move slowly.

In the adaptation of works to ground, the governing factor is the power of the rifle in frontal defence. We have seen that in Peninsula times great reliance was placed on the flanking defence of lines by guns in redoubts. Infantry extended behind a simple line of trench could not resist a strong attack without such obstacles; these have been hitherto necessary as an obstacle. This being so, the enemy's artillery seeks to locate the trenches and to cover them with a steady hail of shells, so as to force the defenders to keep down under cover. If they can succeed in doing this, it is possible for the attacking infantry to advance, and the artillery fire is kept up until the last moment, so that the attack may have the narrowest possible space to cover after the defenders have manned their parapets and opened fire. Fig. 78 shows the action of various natures of projectiles.

From Mil. Engineering, by permission of the Controller of H.M. Stationery Office.

FIG. 78.—Effect of Projectiles.

We need not here discuss the rôle of the defenders' artillery in replying to that of the enemy and playing on the attack; nor for the moment consider how far the defence of the trenches while under artillery fire can be made easier by overhead cover. The main question is—what is, in view of the nature of the attack,
the best disposition of lines of trench; and do they require the addition of redoubts?

The most important point, with the object of protection, is that the trenches must not become conspicuous; this is the best defence against artillery. With the object of resistance by their own fire they must have a good view, or, as it is generally described, *no dead ground* in front of them. For this purpose 300 or 400 yds. may be enough if the ground is even and affords no cover.

This necessity for invisibility, together with the shallowness of the zone that suffices for producing a decisive fire effect, has of late years very much affected the choice of ground for a line of trenches.

For a defensive position on high ground, it was usually laid down until the South African War that a line of trenches should be on the "military crest" ([fr créte militaire]), i.e., the highest point on the hill from which the whole of the slopes in front can be seen. Thus in the three sections of ground shown in fig. 79 it would be at a, b and c respectively. The simplicity of this provision made it attractive and it came to be rather abused in the text-books. There were, even before the improvements in artillery, objections to it. The fire of the trenches was generally found to be at a disadvantage because the lines of sight would be found at very different elevations on different parts of the line, so that by a strict adherence to the rule some of the trenches would be placed near the top of the hill, and some in dangerous isolation near the bottom. Moreover a rounded hill has no military crest.

Further, we have to consider nowadays not only the position of the fire-trenches, but also of supports, reserves, and artillery, and the whole question is extremely difficult.

For instance, considering the sections alone, as if they did not vary along the line, the positions at a and b, fig. 79, are bad because they are on the sky-line and therefore a good mark for artillery. That at c is specially bad because the slope in front is so steep that the defenders would have to expose themselves very much to fire down it, and the artillery fire against them can be kept up until the very last moment. The position c has the advantage of not being on the sky-line, but the position of the supports in rear is exposed.

Such a position as that at d, fig. 80, is good, but protected or concealed communications must be made for the supports coming from c over the brow of the hill.

Another possible position for the infantry line is at f, fig. 81, with the guns on the high ground behind. A ground like this might easily be concealed from the enemy's artillery.

The drawback is that no retirement up the exposed slope would be possible for them, except at night. The fire from f will be grazing, which will be a great advantage as compared with the plunging fire that would be obtained from a position up the hill.

It is idle, however, to give more than the most cursory consideration to sections of imaginary positions. It is only by actual practice on the ground that skill can be attained in laying out positions, and only a trained soldier or a good eye can succeed in it. Briefly, the advantages of view and position given by high ground must be paid for in some degree by exposure to the enemy's artillery; and at least as much consideration—possibly as much labour—must be given to communications with the fire-trenches and the trenches themselves. Irregular ground simplifies the question of concealment but also gives cover to the enemy's approach. The lie of the ground itself dictates the position of the trenches subject to the pre-dispositions of the responsible officer. On flat featureless ground the general trace of the trenches should be irregular. This makes a more difficult target for artillery, and affords a certain amount of covering or blanking fire, which is a very great advantage. Of course care should, however, be taken not to expose the trenches to oblique or enfilade fire; or at least to protect them, if so exposed, by traversing.

Concealment of trenches is generally attempted by covering the freshly turned earth of the small parapets with sods, leafy branches or grass. In this connexion it should be remembered that after a day or two cut leaves and grass wither and may become conspicuous against a green surface. Where the ground is so even that a good view of the foreground is possible from the surface level, the trench may be made without a parapet; but this entails great labour in removing and disposing of the excavated earth. A common device is to conceal the parapet as well as possible and to make a dummy trench some distance away to draw fire.

Besides the direct concealment of trenches, care must be taken that the site is not conspicuous. Thus a trench should not be placed along the meeting line of two different kinds of cultivation, or along the edge of a belt of heather on a hillside, or where a difference of gradient is sharply defined; or where any conspicuous landmark would help the enemy's artillery to get the range.

Trenches are broadly distinguished as "fire trenches" and "cover trenches," according as they are for the firing line or supporting troops. The following simple types are taken from the 1908 edition of *Military Engineering* (part 1): "Field Defences."

Fig. 82 is the most common form of fire trench, in which labour is saved by equalising trench and parapet. This would take 14 to 2 hours in ordinary soil. Fig. 83 shows the same trench improved by 2 or 3 hours' more work. Fig. 84 shows a fire trench without parapet, with cover trench and communication.

The addition of a loophole of sand-bags, sodded on the top for concealment (called *head-cover*), gives increased protection, but at the cost of greater prominence for the parapet (fig. 85). Overhead cover can only be provided in fire trenches by giving the parapet still greater height and it is not usually done. Portions of the trench not used for firing can, however, be given splinter-proof protection by putting over them branches or bundles, covered with a few inches of earth or by boards, or sheets of corrugated iron, if they can be had. A better plan when time permits is to provide cover trenches immediately behind and communicating with the fire trench.

The question of redoubts has been vexed one for years; partly they were thought to be unnecessary in view of the resisting power of a line of trenches, but chiefly because the redoubt was always imagined as one of the older type, with a high conspicuous parapet. Of course a redoubt of such a nature would be readily identified and made untenable. But the idea of a redoubt does not necessarily imply command. Its object is that it shall be capable of all-round defence. There can be no doubt that as there is always a possibility of lines being pierced somewhere, it is desirable, unless the whole line is to be thrown into confusion, to have a force back, to have some point at which the defenders can maintain themselves. This is not possible unless at such points there is provision for defence towards both flanks and rear, that is to say, when there are redoubts, which can hold on after certain portions of the line have been lost and thereby can localize the enemy's success and simplify
the action of supporting troops. In order that redoubts may exercise this function, all that is necessary is that their defenders should be able to see the ground for a furlong in front of them in every direction. Their parapets, therefore, need be in no way more conspicuous than those of the neighbouring fire trenches, and in that case there is no fear of their drawing special attention from the enemy's artillery. Whatever theories may have been put forward on the subject, in practice they are constantly used, and in the Russo-Japanese War, where the experience of South Africa was already available, we find them in the fighting lines on both sides.

In order that redoubts may exercise this function, all that is necessary is that their defenders should be able to see the ground for a furlong in front of them in every direction. Their parapets, therefore, need be in no way more conspicuous than those of the neighbouring fire trenches, and in that case there is no fear of their drawing special attention from the enemy's artillery. Whatever theories may have been put forward on the subject, in practice they are constantly used, and in the Russo-Japanese War, where the experience of South Africa was already available, we find them in the fighting lines on both sides.
The commonest forms of obstacle now used are abatis and wire entanglements. Fig. 93 shows a well-finished type of abatis. The poles are spiked and represented, and the butts are buried and pegged firmly down. Wire entanglement may be added to this with advantage. An abatis should be protected from artillery fire, which is sometimes done by placing it in a shallow excavation with the earth thrown up in front of it.

Obstacles.

From M.I. Engineering, Field Defences, by permission of the Controller H.M. Stationary Office.

Fig. 93.—Abatis.

Wire may be used as a high or low entanglement or as a fence or trip wire or concealed obstacle. The usual form of high wire entanglement consists of several rows of stout stakes 4 or 5 ft. long, driven firmly into the ground about 6 ft. apart, and connected horizontally and diagonally with barred wire.

Palisades are still used, and need no description. They were formerly often made bullet-proof, but this is no longer possible. Fraises are seldom heard of now, though they may appear occasion-ally in a modified form. They were much used in connexion with deep ditches, and are palisades placed so as to project horizontally from the escarp, or sloping failure in the bottom of the ditch. Military pits both deep and shallow (the latter, shown in fig. 95, called trous de loup) are much used, and were formerly, because the obstacle is hardly worth the labour expended on it.

Fig. 94.—Crows’ Feet.

Fig. 95.—Plan and section of Trou de loup.

however, were employed in the Russo-Japanese War. Crows’ feet, formerly much used as a defence against cavalry, are practically obsolete. They consisted of four iron spikes joined together at their bases in such a manner that however they were thrown down one point would always be pointing upwards (fig. 94). Chevaux de frise (g.2) were formerly a much-used type of obstacle.

The best obstacle is that which can be made to fulfil a given object with the least expenditure of time and labour. From this point of view barbed wire is far the best. Its chief advantages is that it gives no cover whatever to the enemy.

Fougasses have always for convenience been classed as obstacles. A fougasse is a small powder box buried at the bottom of a dipping pit. Over the powder is a wooden shield, 3 or 4 in. thick, and over the shield a quantity of stones are piled. The illustration, fig. 96, gives a clear idea of the arrangement. A fougasse of this form, charged with 80 lb. of powder, will throw 5 tons of stone over a surface 160 yds. long by 120 wide. They may be fired by powder hose, fuse or electricity. Their actual effect is very often a matter of chance, but the moral effect is usually considerable.

Dams are most effective obstacles, when circumstances allow of their use. They are constructed by military engineers as small temporary dams would be in civil works.

A most important question, especially in connexion with obstacles, is that of lighting up the foreground at night. Portable electric searchlights are most valuable, especially for detecting the enemy’s movements at some distance; but their use will naturally always be restricted. Star shells and parachute lights fired from guns are not of much use for the immediate foreground, and do not burn very long. They were formerly chiefly of use in siege works, to light up an encamped working parties. Germany has introduced lightbombs fired from pistons, which will probably have a considerable future.

Various civilian forms of signal-light would be very useful to illuminate obstacles, but cannot well be carried in the field. Bonfires are very useful when material is available. They require careful treatment, e.g., they must be so arranged that they can be lighted instantaneously (they may be lighted automatically, by means of a trip wire and a fuse); they must give a bright light at once (this can be ensured with shavings or straw sprinkled with petroleum; they must be firmly built so that the enemy cannot destroy them easily; and if possible there should be a screen arranged behind them so that they may not light up the defence as well as the attack.

Blockhouses are familiar to the public from the part they played in the South African War of 1899-1902. In the old-fashioned permanent fortification they are kept in such positions as re-entering places of arms and built of masonry. Stone blockhouses have long been used in the Blaek for fortifying outposts; they are sometimes built cruciform, so as to get some flank of defence. In the form of barrel- or log-cabins they have played a great part in warfare between pioneer settlers and savages.

From M.I. Engineering, Field Defences, by permission of the Controller H.M. Stationary Office.

Fig. 96.—Fougasse.

In the 19th century blockhouses were usually designed to give partial protection against field artillery; the walls being built of two thicknesses of logs with earth between them, the roof flat and covered with 2 or 3 ft. of earth, and earth being piled against the walls up to the loopholes. Now they are employed only in positions where it is not likely that artillery will be brought against them; but they may be made tenable for a while even under artillery fire if they are surrounded by a trench and parapet.

Blockhouses are especially useful for small posts protecting such points as railway bridges, which the enemy may attempt to destroy by cavalry raids. The essential feature is a bullet-proof loop-holed wall, arranged for all-round fire with enough interior space for the garrison to sleep in. The roof may be simply waterproof. Some arrangement for storing water must be provided. Circular blockhouses were very popular in South Africa. They were made of sheets of corrugated iron fastened 6 in. apart on a wooden framework, the space between the sheets being filled with small stones. The loop-holes were made of sheet-iron frames inserted in the walls.

Fig. 97 shows a section of one of these blockhouses.

By permission of the Controller H.M. Stationary Office.

Fig. 97.—Blockhouse, South Africa, 1900-1902.

The defence of woods was formerly an important branch of field defences. Abatis and entanglements could readily be extemporized, trunks of trees made strong breastworks, and the wood concealed the numbers of the defenders. A wood was therefore generally considered a useful addition to a line of defence.

It was customary to hold the front edge of the wood, the irregularities of the outline being utilized for frontal and flanking fire, while obstacles were dispensed some 300 yds. in front. In a carefully prepared position, clearings would be made parallel to the front and some distance back from it, for support positions, and great attention was paid (in theory at least) to clearing communications, erecting siege-works, &c., so that the defending troops might move freely in any desired direction.

Woods, however, had their inherent drawbacks. The ground is hard to dig, clearing involves great labour; and communication, at the best, is cramped. Nowadays a wood can hardly be considered a strong defensive element in a line. The front of it is an excellent ranging mark for artillery, and positions within the wood are not easily made, because of the difficulty of trenching, and the fact that no reasonable amount of timber will make a breastwork proof against the modern bullet. Once an enemy gets a footing within a wood, the position is more favourable to offensive than to defensive action. If a wood has to be occupied in a line of defence, it is probable that in most cases the rear edge or a line slightly behind it would be the best to fortify, though the front edge would no doubt be held by the fighting line at the outset.

The defence of villages is another question which has been much affected by recent improvements in artillery. Formerly villages were very important adjuncts to a line of defence, and strong points for a detached force to hold. There were indeed always drawbacks. The preparations for defence entitled
CONCLUSION

FORTIFICATION AND SIEGECRAFT

A good deal of labour, and the defending force was scattered in houses at distances, that control and united action were difficult. But the value of the defence was enhanced by its being, on the whole, a success—great—and sometimes even decisive—that villages were occupied as a matter of course. This is certainly now changed, but precisely to what extent this is attributable to the impossibility of the European war. A village under fire is not now an ideal defensive position. A single sharpnel penetrating the outer wall may kill all the members of a family, a single field-howitzer shell may practically ruin a house or a tower. The house or the tower may (without any preliminary labour at all) give very good protection against shell fire to troops behind them. Further, the value of the defence is not diminished by the fact that the attack has been immediately repulsed. It is so great that the ruins of walls and houses occupied at the right moment may prove an impregnable stronghold. This class of fighting, however, does not properly come under the present heading. For the details of the defence of walls, houses, &c., see the official Milt. Engineering (1908).

Entrenching under Fire.—Progress in this direction has been due in large part to the unexpected rise of an instrument invented to produce a tool that shall weigh nothing, go easily in the pocket, and be available as a pick, shovel, saw, hand-axe or corkscrew. A tool that will serve more than one use is seldom satisfactory for any.

The object of entrenching under fire is to enable attacking infantry, when their advance is checked by the enemy’s fire, to maintain the ground they have won by extemporizing cover where none exists. The need of this was first felt in the American Civil War and, indeed, so small a distance as 22 in. long and weighing only 1 lb. was introduced by Brigadier-General H. W. Bemham into the Army of the Potomac. Since that time a great number of patterns have been tried, including shovels of various kinds, spades of various kinds, some of them soldierly and some of them used by the Russian, the American, and the Japanese. The Austrian form of this tool is a rectangular spade with handle. The length over all is a little less than 20 in. The blade is 8 in. long by 6 wide. One side of it has a saw edge, and the other a cutting edge. For carriage, the blade is enclosed in a leather case, which is strapped to the pack or the waist-belt. In the British army the Wallace combined pick and shovel was used for some time, but was eventually dropped. There was always great doubt whether the utility of a portable entrenching tool such as this could be realized in the field, and whether a soldier would carry it. It was, however, established the necessity of it, and also the fact that it must generally be used lying down. For this purpose and convenience in carrying it on the person, a very light short-handled tool is required. The soldier lying down cannot attempt to dig a trench, but can make a little hole by his side as he lies, and put the earth in front of his head. A method introduced by the Japanese is that at each check in the advance the lines should form squares, and the lines fore and aft and the supporting lines in succession should improve the cover thus commenced. The general remarks on the few things that soldiers dislike more, in the way of training, than trenchwork. For men unused to it, it is tiring and tedious work, and it is difficult for them to realize its importance. At the same time it is a commonplace of war that no new men can be as rapidly trained as old. The new men require a rather longer time than the old to learn to use the tools and to get the knack of the job. The modern soldier lives in a field force. As a result, his equipment is simpler and lighter than that of the old soldier. The modern soldier grows his own food, and so the discomfort of the attack. This growth is much less, and the equipment of the field force has developed as the modern soldier grows more able to take care of himself, and his equipment has developed as that one force should succeed in surrounding another stronger than itself, and by entrenching prevent the latter from breaking out and compel its surrender.

VI. CONCLUSION

In tracing the history of the science of fortification and in outlining the practice of our own time it has been necessary to dwell chiefly on the material means of defence and attack. The human element has had to be almost ignored. But more comes in the paradox, that the material means are after all the least important element of defence. Certainly it is inconceivable that the designer of a fortress should not try to make it as strong as is consistent with the object in view and the means at his disposal. And yet while engineers in all ages have sought changes for strength and refinements of strength, the fact remains that the best defences recorded in history owed little to the builder’s art. The splendid defence in 1667 of Candia, whose equestrian, of early Italian design, was already obsolete but whose capture cost the Turks 100,000 men; the three years defence of Ostend in 1601; the holding of Arcot by Clive, are instances that present themselves to the memory at once. The very weight of the odds against them sometimes calls out the best qualities of the defenders, and the most when at his best is worth many times more than the rampart behind which he fights. But it would be a poor dependence deliberately to make a place weak in order to evoke these qualities. One cannot be sure that the garrison will rise to the occasion, and the weakness of the place has very often been found an excuse for giving it up with little or no resistance.

Very much depends on the governor. Hence the French saying, “tand vaut l’homme, tant vaut la place.” Among modern men we think of Todleben (not governor, but the soul of the garrison), at Sevastopol, Fenwick Williams at Kas, Denfert-Rochereau at Belgrad, Pasha at Plevna. The spirit and the genius of the 16th and 17th centuries offer many instances in which the event turned absolutely on the personal qualities of the governor; in some cases distinguished by courage, skill and foresight, in others by incapacity, cowardice or treachery. The reader is referred to Carnot’s Défense des places fortes for a most interesting summary of such cases, one or two of which are quoted below.

Naarden was besieged by the prince of Orange in September 1673, and defended by Philippe de Proces, sieur Dupas. The duck of Luxembourg visited the place some hours before it was invested, and arranged with Dupas to relieve him as soon as he had collected his cavalry. But the governor lost his head when he saw the enemy encamped round the place, and surrendered it before he had even lost the covered way. He was subsequently tried by a council of war and sentenced to be degraded before the troops and imprisoned for life. The reason the court gave for not condemning him to death was that they could find no regulation which would enable a man to lose life for being a coward. (At that period the decapitation of individuals was the only way of showing that they had failed in their duty was not uncommon.) This man, however, was not wanting in physical courage. He was in prison at Grave when it was besieged a year later, obtained leave to take as a volunteer in the defence, fought well and was killed. A similar case occurred in the English Civil War. In 1645 the young governor of the royal port at Bletchington House was entertaining a party of ladies from Oxford, when Cromwell appeared and summoned him to surrender. The attacking force had no firearms more powerful than a carbine, but the governor, terrified by Cromwell’s personality, yielded. Charles I., who was usually merciful to his officers, caused this governor to be shot.
alluded to as questions recognized, but many commanders retained it.

The gallant Marshal d'Essé, who feared nothing but the idea of dying in his bed, was lying ill at his country house when he was seized by the king. He was ordered to take command at Thérouanne, then threatened by Charles V., and made his farewell with these words, which remind us somewhat of Grenville: "Sire, je m'y en vais donc de bon et loyal cœur; mais j'ai oublie que la place est mal entourée, non pas seulement pourvue de palies, de tranches, ni de hottes pour remplacer et remuer la terre; mais lors, quand entendez que Thérouanne est prise, dites hardiment que d'Essé est guéri de sa jaunisse et mort." And he made good his word, for he was killed at the breach by a shot from the arquebus of a Spanish soldier.

Sometimes the ardour of defence inspired the whole body of the inhabitants. Fine examples of this are the defence of Rochelle (1627) and Saint-Jean de Lône (1636), but these are too long to quote. We may, however, mention Livron, which is curious. In 1574 Henry III. sent one of his favourites, Saint Lary Bellegarde, against the Huguenots in the Dauphiné. Being entrusted with a good army, this gentleman hoped to achieve some distinction. He began by attacking the little town of Livron, which had no garrison and was defended only by the inhabitants. But he was repulsed in three assaults, and the women and children conceived such a horror of Sir John Jones's doing, that if he had been commanding a fortress on British soil he would not have thought resistance hopeless as long as there was anything whatever left to defend. The reason why these two men of similar temper are found in opposition is quite simple. When Carnot wrote, the French army occupied most of the important fortresses of Europe, and it was to the interest of the emperor that if attacked they should be held to the last moment, in order to cause the enemy as much delay and loss as possible. Jones, on the other hand, was one of the engineers who had been brought up by the tradition of his profession, and his arguments were prompted by sympathy for his own countrymen whose lives were sacrificed by the prolongation of such resistance.

A century has passed since Carnot and Jones wrote, and the ideas in which they had been educated were those of the pre-Napoleonic era. In the 18th century fortresses were many, good roads few, and campaigns for the most part leisurely. To the European nations of that time, inheritors of a perennial state of war, the idea of concentrating the national resources on a short and decisive campaign had not occurred. The knock-out blow had not been invented. All these conditions are now so changed that new standards must be and indeed have been set up, both for the defence of places and the general employment of fortification.

As regards the conduct of the defence, the massacre of a garrison as a penalty for holding out too long would meet with no sympathy in the present day. On the other hand, the issue of modern wars is worked out so rapidly that if a fortress is well defended, with the advantage of the present weapons, there is always a chance of holding out till the close of the war. If the place is worth holding, it should as a rule be held to the bitter end on the chance of a favourable turn in affairs; moreover, the maintenance of an important siege under modern conditions imposes a severe strain on the enemy and immobilizes a large number of his troops.

In concluding this article some elementary considerations in connexion with the use of permanent defences may be noticed, though the general question of strategic fortification is outside its scope. The objects of fortification differ, as has been shown, from age to age. In former times the chief object was to support the attacks of invaders. Norwegians might find their refuge tower essential, later, a robber-king might look on his castle as so much capital invested; a wealthy medieval town might prove the value of its walls more than once in a generation; a country without a standing army might gain time for preparation by means of fortresses barring the roads across the frontier. But how does the question stand to-day among European countries which can mobilize
The use and abuse of fortresses.

Fortresses do not decide the issue of a campaign; they can only influence it. It is better, therefore, to put all the money the fortress would have cost, and all the man-power that its maintenance implies, into the increase and equipment of the active army. For the fate of the fortress must depend ultimately on the result of the operations of the active armies. Moreover, the very assumption that resources on both sides are equal means that the nation which has spent money on permanent fortifications will have the smaller active army, and therefore condemns itself beforehand to a defensive rôle.

This general negation is only useful as a corrective to the tendency to over-fortify, for such a case cannot occur. In practice there will always be occasion for some use of fortification. A mountain range may lend itself to an economical defence by a few men and some inexpensive barrier forts. A nation may have close to its frontier an important strategic centre, such as a rail head, which makes the position of the frontier fortifications important, which must be protected. In such a case it may be necessary to guard against accidents by means of a fortress. Again, if one nation is admittedly slower in mobilization than the other, it may be desirable to guard one portion of the frontier by fortresses so as to force invasion into a district where concentration against it is easiest.

As for the defence of a capital, this cannot become necessary if it stands at a reasonable distance from the frontier until the active armies have arrived at some result. If the fighting strength has been destroyed by destroying its means of transport, then it is time to consider other positions. In any case, it is not only better, but safer, to have a capital so situated that it cannot be reached unless by the destruction of means of transport.

The case of a weak country with a powerful and aggressive neighbour is in a different category. If she stands alone she will be eaten up in time, fortifications or no fortifications; but if she can reckon on assistance from outside, it may be worth while to expend most of the national resources on permanent defences.

These hypothetical cases have, however, no value, except as illustrations to the most elementary arguments. The actual problems that soldiers and statesmen have to consider are too complex to be dealt with in generalities, and no mere treatise can supply the place of knowledge, thought and practice.

FORTLAGE, KARL (1806–1881), German philosopher, was born at Osnabrück. After teaching in Heidelberg and Berlin, he became professor of philosophy at Jena (1846), a post which he held till his death. Originally a follower of Hegel, he turned to Fichte and Beneke (q.v.), with whose insistence on psychology as the basis of all philosophy he fully agreed. The fundamental idea of his psychology is impulse, which combines representation (which presupposes consciousness) and feeling (i.e. pleasure). Reason is the highest thing in nature, i.e. is divine in its nature, God is the absolute Ego and the empirical egos are his instruments. Fortlage's chief work is: Genetische Geschichte d. Philosoph. seit Kant (Leipzig, 1852); System d. Psych. als empirische Wissenschaft (6 vols., Leipzig, 1855); Dorstung und Kritik der Beweise für das Dasein Gottes (Heidelberg, 1849); Beiträge zur Psych. als Wissensch. (Leipzig, 1875).

FORT LEE, a borough of Bergen county, New Jersey, U.S.A., in the N.E. part of the state, on the W. bank of the Hudson river, opposite the northern part of New York City. Pop. (1905) 3433; (1910) 4472. It is connected with the neighbouring towns of Jersey City and Elizabeth by electric and suburban railways, of which it is a residential suburb. The main part of the borough lies along the summit of the Palisades; north of Fort Lee is an Interstate Palisades Park. Early in the War of Independence the Americans erected here a fortification, first called Fort Constitution but later renamed Fort Lee, in honour of General Charles Lee. The name of the fort was subsequently applied to the village that grew up in its vicinity. From the 15th of September until the 20th of November 1776 Fort Lee was held by Gen. Nathanael Greene with a garrison of 3500 men, but the capture by the British of Fort Washington on the opposite bank of the river and the crossing of the Hudson by Lord Cornwallis with 5000 men made it necessary for Greene to abandon this post and join Washington in the famous "retreat across the Jerseys." An attempt to recapture Fort Lee was made by General Anthony Wayne in 1780, but was unsuccessful. On the site of the fort a monument, designed by Carl E. Tefft and consisting of heroic figures of a Continental trooper and drummer boy, was erected in 1908. The borough of Fort Lee was incorporated in 1904.

FORT MADISON, a city and the county-seat of Lee county, Iowa, U.S.A., on the Mississippi river, in the S.E. corner of the state, and about 20 m. S.W. of Burlington. Pop. (1890) 7901; (1900) 9278, of whom 1025 were foreign-born; (1910) 8767; (1920) 8900. Fort Madison is served by the Atchison, Topeka & Santa Fé (which has repair shops here) and the Chicago, Burlington & Quincy railways. The city has various manufactures, including canned goods, chairs, paper and farm implements; the value of its factory product in 1905 was $2,378,802, an increase of 99.8% over that of 1900. Fort Madison is the seat of one of Iowa's penitentiaries. A stockade fort was erected on the site in 1832, but it was burned in 1833. The town was permanently settled in 1833, Fort Madison was laid out as a town in 1836, and was chartered as a city in 1839.

FORTROSE ('Gaelic for Tros, "the wood on the promontory"'), a royal and police burgh, and seaport of the county of Ross and Cromarty, Scotland. Pop. (1901) 1770. It is situated on the south-eastern coast of the peninsula of the Black Isle, 8 m. due N.E. of Inverness, 26½ m. by rail. It is the terminus of the Black Isle branch of the Highland railway; there is communication by steamer with Inverness and also with Fort George, 2½ m. distant, by ferry from Chanonry Ness. Fortrose consists of the two towns of Rosemarkie and Chanonry, about 1 m. apart, which were united into a free burgh by James II. in 1455 and created a royal burgh in 1590. It is a place of considerable antiquity, a monastery having been established in the 6th century by St Moluag, a friend of Columba's, and St Peter's
church built in the 8th century. In 1124 David I. instituted
the bishopric of Ross, with its seat here, and the town acquired
some fame for its school of theology and law. The cathedral
is believed to have been founded in 1330 by the countess of Ross
(her canopied tomb, against the chancel wall, still exists) and
finished in 1485 by Abbot Fraser, whose previous residence at
Melrose is said to account for the Perpendicular features of his
portion of the work. It was Early Decorated in style, cruciform
in plan, with bold red sandstone, but all that is left are the
south aisles of the nave and the chancel, with the chapter-house,
two-storeyed structure, standing apart near the north-eastern
corner. The cathedral and bishop’s palace were destroyed by
order of Cromwell, who used the stones for his great fort at
Inverness.

Anchorage of the port survives in the bell of 1460. These
ruins form the chief object of interest in the town, but
other buildings include the academy and the Black Isle com-

bination poorhouse. The town is an agricultural centre of
some consequence, and the harbour is kept in repair. Rosemarkie,
in the churchyard of which is an ancient Celtic cross, is much
resorted to for sea-bathing, and there is a golf course in Chanonry
Ness. The burgh belongs to the Inverness district group of
parliamentary burghs.

FORT SCOTT, a city and the county-seat of Bourbon county,
Kansas, U.S.A., on the Marmaton river, about 100 m. S.
of Kansas City, Missouri. Pop. (1860) 5372; (1869) 11,945;
(1900) 10,322, of whom 1205 were negroes; (1910 census)
10,463. It is the point of intersection of the Kansas City, Fort
Scott & Memphis (St. Louis & San Francisco system),
the Missouri, Kansas & Texas, and the Missouri Pacific railways,
and has in consequence a large traffic. The city is built on a
rolling plain. Among its institutions are an Epworth house
(1899), Mercy hospital (1886), the Goodlander home, and a
Carnegie library. Near the city there is a national cemetery.
Fort Scott is in the midst of the Kansas mineral fields, and its
trade in bituminous coal is especially important. Building
stones, cement rock, clays, oil and gas, lead and zinc are also
found in the neighbourhood. An excellent white sulphur water
is procured from artesian wells about 800 ft. deep, and there is
a mineral-water bath house. The city is also a trading centre
for a rich farming region, and is a horse and mule market of
considerable importance. Among its manufactures are mat-
tresses, syrup, bricks, pottery, cement and foundry products.
In 1905 the total value of the city’s factory product was
$1,340,026, being an increase of 85% since 1900. The city
owns and operates its waterworks. The fort after which the
city was named was established by the Federal government in
1822, at a time when the whole of eastern Kansas was still parcellled
out among the Indian tribes; it was abandoned in 1855. The
town was platted in 1857, and Fort Scott was chartered as a
city in 1880.

FORT SMITH, a city and the county-seat of Sebastian county,
on the extreme W. border of Arkansas, U.S.A., lying about
440 ft. above sea-level, on the S. bank of the Arkansas river,
at its junction with the Poteau, and at the point where the
Arkansas breaks through the Boston mountains. Pop. (1890)
11,311; (1900) 11,587, of whom 2497 were of negro descent and
684 foreign-born; (1910 census) 21,975. Transportation
is afforded by river and by railways. The Arkansas, San
Francisco, the St. Louis, Iron Mountain & Southern, the
Arkansas Central, the Fort Smith & Western, the Midland Valley
and the Kansas City Southern. A belt line runs the business
centre of the city facilitates freight transfers. Some of
the business streets are unusually broad, and the streets in the
residential district are well shaded. Fort Smith is the business
centre of a fine agricultural country and of the Arkansas coal
and natural gas region. It has extensive wholesale and retail
merchandise, and a large miscellaneous trade, partly in its own
manufactures, among which are cotton and timber products,
chairs, mattresses and other furniture, wagons, brooms and
bricks. In 1905 the total value of the factory product was
$2,339,045, an increase of 66-4% since 1900. The public
schools have a rich endowment: the proceeds of lands (about
200 acres) once belonging to the local military reservation,
which—except the part occupied by a national cemetery—was
given by Congress to the city in 1884. Near the centre of the
city are a Catholic academy, convent and infirmary; and there
is a Carnegie library. A United States army post was established
here in 1617; the town was laid out in 1621; and the county
was created in 1851. Fort Smith was incorporated as a town
in 1846, and was chartered as a city in 1845. All transportation
was by river and wagon until 1866, when the railway was
completed from Little Rock. The military post, in earlier years
the chief depot for the western forts, was abandoned in 1871.
During the Civil War Fort Smith was strongly in sympathy with
the Confederacy. The fort was seized by state troops in April
1861, and was reoccupied by the Union forces in September
1863. There was considerable unrest due to border “bush-
whacking” throughout the war, and several skirmishes took
place here in 1864. The area of the city was more than doubled
in 1905.

FORTUNATIANUS, Atilius, Latin grammarian, flourished
in the 4th century a.D. He was the author of a treatise on
metre, dedicated to one of his pupils, a youth of senatorial rank,
who desired to be instructed in the Horatian metres. The manu-

script opens with a discussion of the fundamental ideas of
metre and the chief rules of prosody, and ends with a detailed
analysis of the metres of Horace. The chief authorities used
were Caesius Bassus and the Latin adaptation by Juba the
grammarian of the Teukô of Heliodorus. Fortunatianus being a
Greek name in the African provinces, it is probable that the
author was a countryman of Juba, Terentianus Maurus and
Victorinus.

Editions of the Ars in II. Kell, Grammatice Latinii, vi., and separately
by him (1885).

FORTUNATUS, the legendary hero of a popular European
chap-book. He was a native, says the story, of Samugata
in Cyprus, and meeting the goddess of Fortune in a forest received
from her a purse which was continually replenished as often as
he drew from it. With this he wandered through many lands,
and at Cairo was the guest of the sultan. Among the treasures
which the sultan showed him it was an old necklace, but which
had the power of transporting its wearer to any place he desired.
Of this he feehoniously possessed himself, and returned to
Cyprus, where he led a luxurious life. On his death he left the
FORTUNATUS—FORT WAYNE

purse and the hat to his sons Ampredo and Andelosia; but they were jealous of each other, and by their recklessness and folly soon fell on evil days. The moral of the story is obvious: men should desire reason and wisdom before all the treasures of the world. In its full form the history of Fortunatus occupies in Karl Simrock's Die deutschen Volksbücher, vol. iii., upwards of 158 pages. The scenes are continually shifted—from Cyprus to Flanders, from London, from London to France, and a large number of secondary characters appear. The style and allusions indicate a comparatively modern date for the authorship; but the nucleus of the legend can be traced back to a much earlier period. The stories of Jonathas and the three jewels in the Gesta Romanorum, of the emperor Frederick and the three precious stones in the Cento Novelle antiche, of the Mazin of Khorassan in the Thousand and one Nights, and the flying scaffold in the Bahar Danush, have all a certain similarity. The earliest known edition of the German text of Fortunatus appeared at Augsburg in 1509, and the modern German investigators are disposed to regard this as the original form. Innumerable versions occur in French, Italian, Dutch and English. The story was dramatized by Hans Sachs in 1555, and by Thomas Dekker in 1600; and the latter's comedy appeared in a German translation in Englische Komödien und Tragödien, 1620. Ludwig Tieck has utilized the legend in his Phantasus, and Adelbert von Chamisso in his Peter Schlemil!; and Ludwig Uhland left an unfinished narrative poem entitled "Fortunatus and his Sons." The German painters' most remarkable Fortunatus and his stöhne, eine Zauber-Tragödie, von Thomas Decker, mit einem Anhang, &c. (Berlin, 1819); Joseph Johann Görres, Die deutschen Volksbücher (1807).

FORTUNATUS, VANENIUS HONORIUS CLEMENTIANUS (530-609), bishop of Poitiers, and the chief Latin poet of his time, was born next Ceneda in Tresvo in 530. He studied at Milan and Ravenna, with the special object of excelling as a rhetorician and poet, and in 565 he journeyed to France, where he was received with much favour at the court of Sigbert, king of Austrasia, whose marriage with Brunhild he celebrated in an epikhalamium. After remaining a year or two at the court of Sigbert he traveled in various parts of France, visiting persons of distinction, and composing short pieces of poetry on any subject that occurred to him. At Poitiers he visited Queen Radegunda, who lived there in retirement, and she induced him to prolong his stay in the city indefinitely. Here he also enjoyed the friendship of the famous Gregory of Tours and other eminent ecclesiastics. He was elected bishop of Poitiers in 599, and died about 609. The later poems of Fortunatus were collected in 11 books, and consist of hymns (including the Vexilla regis profus), Englished by J. M. Madrazo, a painter, and Alexander of 1870. The royal poet was fond of sonnets, epigrams, poetical epistles, and verses in honour of his patroness Radegunda and her sister Agnes, the abbess of a nunnery at Poitiers. He also wrote a large poem in 4 books in honour of St. Martin, and several lives of the saints in prose. His prose is stiff and mechanical, but most of his poetry has an easy rhythmical flow.

An edition of the works of Fortunatus was published by C. Brower at Fulda in 1663 (2nd ed., Mainz, 1617). The edition of M. A. Lusch (Rome, 1785) was afterwards reprinted in Migne's Patrologiae cursus completus, vol. lxxxvii. See the edition by Leo and Kursch (Berlin, 1856 and 1885). There are French lives by Nisard (1886) and Leroux (1885).

FORTUNE, ROBERT (1833-1880), Scottish botanist and traveller, was born at Kelso in Berwickshire on the 16th of September 1813. He was employed in the botanical garden at Edinburgh, and afterwards in the Royal Horticultural Society's garden at Chiswick, and upon the termination of the Chinese War in 1842 was sent out by the Society to collect plants in China. His travels resulted in the introduction to Europe of many beautiful flowers; but another journey, undertaken in 1848 on behalf of the East India Company, had much more important consequences, occasioning the successful introduction into India of the tea-plant. In subsequent journeys he visited Formosa and Japan, described the culture of the silkworm and the manufacture of rice paper, and introduced many trees, shrubs and flowers now generally cultivated in Europe. The incidents of his travels were related in a succession of interesting books. He died in London on the 13th of April 1860.

FORTUNY, MARIANO JOSE MARIA BERNARDO (1838-1874), Spanish painter, was born at Reus on the 11th of June 1836. His parents, who were in poor circumstances, sent him first to school to the primary school of his native town, where he received some instruction in the rudiments of art. When he was twelve years old his parents died and he came under the care of his grandfather, who, though a joiner by trade, had made a collection of wax figures, with which he was travelling from town to town. In the working of this show the boy took an active part, modelling and painting many of the figures; and two years later, when he reached Barcelona, the cleverness of his handwork made so much impression on some people in authority there that they induced the municipality to make him an allowance of forty-two francs monthly, so that he might be enabled to go through a systematic course of study. He entered the Academy of Barcelona and worked there for four years under Claudio Lorenzale, and in March 1857 he gained a scholarship that entitled him to complete his studies in Rome. Then followed a period of more than two years, during which he laboured steadily at copies of the old pictures to which he had access at Rome. To this period an end was put by the outbreak of the war between Spain and the emperor of Morocco, as Fortuny was sent by the authorities of Barcelona to paint the most striking incidents of the campaign. The expedition lasted for five months only, but it gave him an impression that was powerful enough to affect the whole course of his subsequent development, and to implant permanently in his mind a preference for the glitter and brilliance of African colour. He returned to Spain in the summer of 1860, and was commissioned by the city of Barcelona to paint a large picture of the capture of the camps of Muley-el-Abbas and Muley-el-Hamed by the Spanish army. After making a large number of studies he went back to Rome, and began the composition on a canvas fifteen metres long; but though it occupied much of his time during the next few years, he never finished it. He busied himself instead with a wonderful series of pictures, mostly of great size, in which he showed an astonishing command over vivacities of technique and modulations of colour. He visited Paris in 1868 and shortly afterwards married the daughter of Federico Madrazo, the director of the royal museum at Madrid. Another visit to Paris in 1870 was followed by a two years' stay at Granada, but then he returned to Rome, where he died somewhat suddenly on the 21st of November 1874 from an attack of malarial fever, contracted while painting in the open air at Naples and Portici in the summer of 1874.

The work which Fortuny accomplished during his short life is distinguished by a supersatellite faculty of execution and a marvellous cleverness in the arrangement of brilliant hues, but the qualities of his art are those that are attainable by a master of technical resource rather than by a deep thinker. His insight into subtleties of illumination was extraordinary, his dexterity was remarkable in the extreme, and as a colourist he was vivacious to the point of extravagance. At the same time in such pictures as "La Vicaria" and "Choosing a Model," and in some of his Moorish subjects, "Moors Playing with a Vulture," he showed himself to be endowed with a sensitive appreciation of shades of character and a thorough understanding of the peculiarities of a national type. His love of detail was instinctive, and he chose motifs that gave him the fullest opportunity of displaying his readiness as a craftsman.

See Daviller, Fortuny, sa vie, son œuvre, sa correspondance, &c. (Paris, 1876); C. Yriarte, Fortuny (Artistes célèbres série) (Paris, 1893); (A. L. & L. E.)

FORT WAYNE, a city and the county-seat of Allen county, Indiana, U.S.A., 102 m. N.E. of Indianapolis, at the point where the St. Joseph and St. Mary's rivers join to form the Maumee river. Pop. (1850) 26,880; (1890) 35,353; (1900) 45,115, of whom 6791 were foreign-born; (1910) Census 63,933. It is served by the Cincinnati, Hamilton & Dayton, the Fort Wayne,
FORT WILLIAM—FORT WORTH

Cincinnati & Louisville, the Grand Rapids & Indiana, the Lake Shore & Michigan Southern, the New York, Chicago & St. Louis, the Pennsylvania and the Wabash railways, and also by interurban electric lines. The site of the city is high (about 770 ft. above sea-level) and level, and its land area was in 1906 a little more than 6 sq. m. The streets are laid out on a rectangular plan and bordered by a profusion of shade trees. The city has several parks, including Lawn Park (31 acres), in which there is a monument in honour of Major-General Henry Ware Lawton (1843–1890), who lived in Fort Wayne for a time. Lake Side Park (22 acres), Reservoir Park (13 acres), Piqua Park (1 acre), and Old Fort Park (1 acre), which is on the site of Old Fort Wayne. Educational institutions include the German Concordia Collegium (Lutheran), founded in 1839, and having 220 students in 1908, and the state school for feeble-minded youth (1879). The city has a Carnegie library.

Fort Wayne is one of the most important railway centres in the Middle West, and several railways maintain here their principal car and repair shops, which add greatly to the value of its manufacturing industries; in 1905 it ranked first among the cities in the state in the value of cars constructed and repaired by steam-railway companies. The other manufactories include foundries and manufacturing shops devoted to the production of rolling mills, sash and door, car-wheel, electrical machinery, and woodware factories and flour mills. In 1905 the total value of the factory product of the city was $15,129,562, showing an increase of 34.3% since 1900.

The Miami Indians had several villages in the immediate neighbourhood, and the principal one, Kekionaga (Miami Town or Great Miami Village), was situated on the E. bank of the St Joseph river, within the limits of the present city. On the E. bank of the St Mary's a French trading post was built about 1686. In 1749–1750 the French fort (Fort Miami) was moved to the E. bank of the St Joseph. The English occupied the fort in 1760 and Pontiac captured it in May 1763, after a siege of more than three months. In 1790 the Miami villages were destroyed. In September 1794 General Anthony Wayne built on the S. bank of the Maumee river the stockade fort which was named in his honour, the site of which forms the present Old Fort Park. By the treaty of Greenville, concluded by General Wayne on the 3rd of August 1795, a piece of land 6 sq. m. in area, including the tract of the Miami towns, was ceded to the United States, and free passage to Fort Wayne and down the Maumee to Lake Erie was guaranteed to the people of the United States by the Indians. By the treaty of Fort Wayne, concluded by General W. H. Harrison on the 7th of June 1803, the tract about Vincennes reserved to the United States by the treaty of Greenville was described and defined; by the second treaty of Fort Wayne, concluded by Harrison on the 30th of September 1809, the Indians sold to the United States about 2,000,000 acres of land, mostly S.E. of the Wabash river. In September 1813 Fort Wayne was besieged by Indians, who withdrew on the arrival, on the 11th of September, of General Harrison with about 2700 men from Kentucky and Ohio. The fort was abandoned on the 19th of April 1819 and no trace of it remains. The first permanent settlement here was made in 1815, and the village was an important fur-trading depot until 1830. The opening of the Wabash & Erie canal in 1843 stimulated its growth. A town was platted and was made the county-seat in 1824; and in 1840 Fort Wayne was chartered as a city.

See W. A. Bierce, History of Fort Wayne (1888); John B. Dillon, History of Indiana, from its Earliest Exploration by Europeans to the Close of the Territorial Government in 1816 (Indianapolis, Ind., 1889); and Charles E. Slocum, History of the Maumee River Basin (Defiance, Ohio, 1900).

FORT WILLIAM, the principal town of Thunder Bay district, Ontario, Canada, 426 m. (by rail) E.S.E. of Winnipeg, on the Kaministikwa river, about a mile from Lake Superior. It is the lake terminus of the Canadian Pacific railway, of the new Grand Trunk Pacific railway, and of several steamship lines. Fort Arthur, the terminus of the Canadian Northern railway, lies 4 m. to the N.E. Fort William contains numerous grain elevators, railway repair shops and docks, and has a large export trade in grain and other farm produce. Minerals are also exported from the mining district, of which it is the centre. Industries, such as saw, planing and flour mills, have also sprung up. The population was 4800 in 1901, but has since increased with great rapidity.

FORT WILLIAM, a police burgh of Inverness-shire, Scotland. Pop. (1901) 2087. It lies at the north-eastern end of Loch Linne, an arm of the sea, about 62 m. S.S.W. of Inverness by road or canal, and was, in bygone days, one of the keys of the Highlands. It is 1223 m. N.E. of Glasgow by the West Highland railway. The fort, at first called Kilmallie, was built by General Monk in 1690, to hold the Old Pretender in subjection, and was enlarged in 1690 by General Hugh Mackay, who renamed it after William III., the burg then being known as Maryburgh in honour of his queen. Here the perpetrators of the massacre of Glencoe met to share their plunder. The Jacobites unsuccessfully besieged it in 1715 and 1746. The fort was dismantled in 1860, and demolished in 1860 to provide room for the railway and the station. Amongst the public buildings are the Belford hospital, public hall, court house and the low-level meteorological observatory, constructed in 1897, which was in connexion with the investigation of the Ben Nevis mill, which was opened in 1904. Its great industry is distilling, and the distilleries, about 2 m. N.E., are a familiar feature in the landscape. Beyond the railway station stands the obelisk to the memory of Ewen Macalchan (1775–1822), the Gaelic poet, who was born in the parish. Fort William is a popular tourist resort and place of call for the steamer passing through the Caledonian canal. The town is the point from which the ascent of Ben Nevis—43 m. E.S.E. as the crow flies—is commonly made. At Corpach, about 2 m. N., the Caledonian canal begins, the series of locks between here and Bazavie—within little more than a mile—being known as "Neptune's Staircase." Both the Lochy and the Nevis enter Loch Linne immediately to the north of Fort William. A mile and a half from the town, on the Lochy, stands the grand old ruin of Inverlochy Castle, a massive quadrangular pile with a round tower at each corner, a favourite subject with landscape painters. Close by is the scene of the battle of the 2nd of February 1645, in which Montrose completely defeated the Earl of Argyll. The modern castle, in the Scottish Baronial style, 1½ m. to the N.E. of this stronghold and farther from the river, is the seat of Lord Aboyne and the Duke of Argyll.

FORT WORTH, a city and the county-seat of Tarrant county, Texas, U.S.A., about 30 m. W. of Dallas, on the S. bank of the West Fork of the Trinity river. Pop. (1880) 6663; (1890) 23,076; (1900) 26,688, of whom 1793 were foreign-born and 4249 were negroes; (1910, census) 73,372. It is served by the Chicago, Rock Island & Gulf, the Fort Worth & Denver City, the Fort Worth & Rio Grande, and the St Louis, San Francisco & Texas of the "Frisco" system, the Gulf, Colorado & Santa Fé, the Houston & Texas Central, the International & Great Northern, the Missouri, Kansas & Texas, the St Louis South-Western, the Texas Pacific, and the Trinity & Brazos Valley (Colorado & Southern) railways. Fort Worth is beautifully situated on a level space above the river. It is the seat of Fort Worth University (coeducational), a Methodist Episcopal institution, which was established as the Texas Wesleyan College in 1881, received its present name in 1888, comprises an academy, a college of liberal arts and sciences, a conservatory of music, a law school, a medical school, a school of commerce, and a department of oratory and elocution, and in 1907 had 802 students; the Polytechnic College (coeducational), which was opened in 1890, has preparatory, collegiate, normal, commercial, and fine arts departments and a summer school, and in 1906 had 12 instructors and (altogether) 606 students; the Texas masonic manual training school; a kindergarten training school; St Andrews school (Protestant Episcopal), and St Ignatius Academy (Roman Catholic). There are several good business, municipal and county buildings, and a Carnegie library. On the 3rd of April 1909 a fire destroyed ten blocks in the centre of the city. Fort Worth lies in the
midst of a stock-raising and fertile agricultural region; there is an important stockyard and packing establishment just outside the city; and considerable quantities of cotton are raised in the vicinity. Among the products are packed meats, flour, beer, trunks, crackers, candy, paint, ice, paste, cigars, clothing, shoes, mattresses, woven wire beds, furniture and overalls; and there are foundries, iron rolling mills and tanneries. In 1905 the total value of the city's factory product was $5,688,391, an increase of 62.5% since 1900; Fort Worth in 1900 ranked fifth among the cities of the state in the value of its factory product; in 1905 it ranked fourth. Fort Worth's numerous railways have given it great importance as a commercial centre. The municipality owns and operates the waterworks and the electric-lighting plant.

A military post was established here in 1849, being called first Camp Worth and then Fort Worth. It was abandoned in 1853. A settlement grew up about the fort, and the city was incorporated in 1873. The fort and the settlement were named in honour of General William Jenkins Worth (1794-1849), a native of Hudson, New York, who served in the War of 1812, commanded the United States forces against the Seminole Indians in 1814-1815, served under General Taylor and General Scott in the Mexican War, distinguishing himself at Monterey (where he earned the brevet of major-general) and in other engagements, and later commanded the department of Texas. In 1907 Fort Worth adopted a commission form of government.

**FORTY**, the cardinal number equal to four tens. The word is derived from the O. Eng. *fœvere*, a combination of *fœw* and *ēr*, an old form of *"en*" used as a suffix, cf. Icel. *tía*, Dan. *ti*, ten, and Ger. *vierzig*, forty. The name "The Forty" has been given to various bodies composed of that number of members, particularly to a judicial body in ancient Athens, which tried small cases in the rural districts, and to a court of criminal jurisdiction and two civil appeal courts in the Venetian republic. The French Academy (see Academis) has also been known as "The Forty" or "The Forty Immortals." The period just before the repeal of the corn laws in the United Kingdom is frequently alluded to, particularly by the free trade school, as the "hungry forties"; and the "roaring forties" is a sailor's name for the stormy region between the 40th and 50th latitudes N. and S., but more particularly applied to the portion of the north Atlantic lying between those latitudes.

**FORUM** (Lat. from *foris*, "out of doors"), in Roman antiquity, any open place used, like the Greek *agora*, for the transaction of mercantile, judicial or political business, sometimes merely as a promenade. It was level, open and surrounded by public buildings, banks of law and other public buildings. In the laws of the Twelve Tables the word is used of the vestibule of a tomb (Cicero, *De legibus*, ii. 24); in a Roman camp the forum was an open place immediately beside the praetorium; and the word was no doubt originally applied generally to the space in front of any public building or gateway in Rome (q.v.) itself, however, during the period of the early history, forum was almost a proper name, denoting the flat and formerly marshy space between the Palatine and Capitoline hills (also called Forum Romanum), which was probably even during the republican period, although not the accommodation necessary for such public meetings as could not be held within the area Capitolina. In early times the Forum Romanum was used for athletic games, and over the porticoes were galleries for spectators; there were also shops of various kinds. But with the growth of the city and the increase of provincial business, more than one forum became necessary, and under the empire a considerable number of *civilia* (judicial) and *venta* (mercantile) fora came into existence. In addition to the Forum Romanum, the Fora of Caesar and Augustus belonged to the former class; the Forum Boarium (cattle), Hortii (vegetable), Saeclum (fish), Pisitorium (breads), Vinarium (wine), to the latter. The Fora of Nerva (also called *transitorium* or *pervium*, because a main road led through it to the Forum Romanum), Trajan, and Vespasian, although partly intended to facilitate the course of public business, were chiefly erected to embellish the city. The construction of separate markets was not, however, necessarily the rule in the provincial fora; thus, in Pompeii, at the north-east end of the forum, there was a *macellum* (market), and shops for provisions and possibly money changers, and on the east side a building supposed to have been the booths of the Lucus Satyrorum, a gateway in North Africa (a military colony founded under Trajan) the whole of the south side of the forum was occupied by shops. The forum was usually paved, and although on festive occasions chariots were probably driven through, it was not a thoroughfare and was enclosed by gates at the entrances, of which traces have been found at Pompeii. When the sites for new towns were being selected, that for the forum was in the centre, and the two main streets crossed one another close to but not through it. At Timgad the main streets are some 5 or 6 ft. lower than the forum. The word *forum* frequently appears in the names of Roman market towns; as, for example, in Forum Appii, Forum Julii (Frefius), Forum Livii (Forili), Forum Sempronii (Fosbornre). These fora were distinguished from mere *sici* by the possession of a municipal organization, which, however, was less complete than that of a prefecture. In legal phraseology, which distinguishes the forum communis from the forum privilegium, and the forum generale from the forum speciale, the word is practically equivalent to "court" or "jurisdiction."

**Forum Clodia** at Rome, see Rome: Archaeology, and works quoted.

**FORUM APPII**, an ancient post station on the Via Appia, 43 m. S.E. of Rome, founded, no doubt, by the original constructor of the road. Herace mentions it as the usual halt at the end of the first day's journey from Rome, and describes it as full of boatmen and cheating innkeepers. The presence of the former was due to the fact that it was the starting-point of a canal which ran parallel to the road through the Pompinea Marshes, and was used instead of it at the time of Strabo and Horace (see Apia, Via). It was mentioned also as a halting place in the account of Paul's journey to Rome (Acts xxviii. 15). Under Nerva and Trajan the road was repaired; one inscription records expressly the paving with tiles (replacing the former graveling) of the section from Tripontium, 4 m. N.W., to Forum Appii; the bridge near Tripontium was similarly repaired, and that at Forum Appii, though it bears no inscription, is of the same style. Only scanty relics of antiquity have been found here; a post station was placed here by Pius VI. when the Via Appia was reconstructed.

(T. As.)

**FORUM CLODII**, a post station on the Via Clodia, about 23 m. N.W. of Rome (not 32 m. as in the Antonine Itinerary), and above the western bank of the Lake of Bracciano, and connected with the Via Cassia at Vacanae by a branch road which ran round the N. side of the lake (Ann. Inst., 1859, 43). The site is marked by the church of SS. Marcus, Marcianus and Liberatus, which was founded in the 8th or 9th century A.D. Inscriptions mentioning the Foro-Clodiienses have come to light on the spot; and an inscription of the Augustan period, which probably stood over the door of a villa, calls the place Pauluslyton—a name justified by the beauty of the site. See Notizie degli scavi (1889), 5; D. Vaglietti, *ibid.* (1895), 342.

**FORUM TRAIANI** (mod. Forlione), an ancient town of Sardinia, on the river Tirusus (Tirso), and a station on the Roman road through the centre of the island from Carales to Olbia and Turris Libisonis. Many of its ruins have been destroyed since 1860. The best preserved are the baths, erected over hot mineral springs. The tanks for collecting the water and the large central piscina are noteworthy. The bridge over the Tirso has been to some extent modernized. On the opposite bank are the scanty remains of an amphitheatre. Not far off is a group of nuraghi, of which that of St Barbara in the commune of Villanova Truschiedda is one of the finest.

See Taramelli in *Notizie degli scavi* (1903), 499.

**FOSBROKE, THOMAS DUDLEY** (1770-1842), English antiquary, was born in London on the 27th of May 1770. He was educated at St Paul's school and Pembroke College, Oxford,
graduating M.A. in 1792. In that year he was ordained and became curate of Horsley, Gloucestershire, where he remained till 1810. He then removed to Wallingford, Herefordshire, where he remained till 1830, and afterward as vicar. His first important work, British Monachism (2 vols., 1802), was a compilation, from manuscripts in the British Museum and Bodleian libraries, of facts relating to English monastic life. In 1799 Fosbrook was elected a fellow of the Society of Antiquaries. The work for which he is best remembered, the Encyclopædia of Antiquities, appeared in 1824. A sequel to this, Foreign Topography, was published in 1828. Fosbrook published many other volumes. He died at Wallingford on the 26th of January 1830.

FOSCARI, FRANCESCO (1337–1457), doge of Venice, belonging to a noble Venetian family, and held many of the highest offices of the republic—ambassador, president of the Forty, member of the Council of Ten, inquisitor, procurator of St Mark, avogadore di comun, &c. His first wife was Maria Priuli and his second Maria Nani; of his many children all save one son (Jacopo) died young. But although a capable administrator he was ambitious and adventurous, and the reigning doge Tommaso Mocenigo, when speaking on his death in 1457, described him as one of the successors to the council against electing Foscari, who, he said, would perpetually plunge the republic into disastrous and costly wars. Nevertheless Foscari was elected (1443) and reigned for thirty-four years. In proclaiming the new doge the customary formula which recognized the people's share in the appointment and asked for their approval—the last vestige of popular government—was finally dropped.

Foscari's reign bore out Mocenigo's warning and was full of wars on the terra firme, and through the doge's influence Venice joined the Florentines in their campaign against Milan, which was carried on with varying success for eight years. In 1450 an attempt was made on Foscari's life by a noble to whom he had refused an appointment; and three years later a conspiracy of young bloods to secure the various offices for themselves by illicit intrigues was discovered. These events, as well as the long and expensive wars and the unsatisfactory state of Venetian finances, induced Foscari to ask permission to abdicate, which was, however, refused. In 1444 began that long domestic tragedy by which the name of Foscari has become famous. The doge's son Jacopo, a cultivated and intelligent but frivolous and irresponsible youth, was in that year accused of the serious crime of having accepted presents from various citizens and foreign princes who either desired government appointments or wished to influence the policy of the republic. Jacopo escaped, but was tried in contumacy before the Council of Ten and condemned to be exiled to Napoli di Romania (Nauplia) and to have his property confiscated. But the execution of the sentence was delayed, as he was lying ill at Trieste, and eventually the penalty was commuted to banishment at Treviso (1446). Four years later Ermolao Donato, a distinguished official who had been a member of the Ten at the time of the trial, was assassinated and Jacopo Foscari was suspected of complicity in the deed. After a long inquiry he was brought to trial for the second time, and although all the evidence clearly pointed to his guilt the judges could not obtain a confession from the accused, and so merely banished him to Candia for the rest of his life, with a pension of two hundred ducats a year. In 1456 the council received information from the rector (governor) of Candia to the effect that Jacopo Foscari had been in treasonable correspondence with the duke of Milan and the sultan of Turkey. He was summoned to Venice, tried and condemned to a year's imprisonment, to be followed by a return to his place of exile. His aged father was allowed to see him while in prison, and to Jacopo's entreaties that he should obtain a full pardon for him, he replied advising him to bear his punishment without protest. When the year was up Jacopo returned to Candia, where he died in the following year. Foscari's career was one of most intense sorrow and grief at this bereavement and became quite incapable of attending to business. Consequently the council decided to ask him to abdicate; at first he refused, but was finally obliged to conform to their wishes and resigned on a yearly pension of 100 ducats. Within a few years Pasquale Malipiero was elected in his place and two days later (1st of November 1457) Francesco Foscari was dead.

The story is a very sad and pathetic one, but legend has added many picturesque though quite apocryphal details, most of them to show how the ineptitude of the Venetian authorities, whereas, as we have shown, he was treated with exceptional leniency. The most accurate account is contained in S. Raimondi's Storia documentata di Venezia, lib. x. cap. iv. vol. ii. and x. (Venice, 1842), which contains the original letters and a final dissertation; see also Pasquale I due Foscari (Turin, 1852). Among the poetical works on the subject Byron's tragedy is the most famous (1821), and Rover's poem Ilios (1821), which was entitled I du Foscari.

FOSCOLO, UGO (1778–1827), Italian writer, was born at Zanze in the Ionian Isles on the 26th of January 1778. On the death of his father, a physician at Spalato, in Dalmatia, the family removed to Venice, and in the University of Padua Foscolo prosecuted the studies begun in the Dalmatian grammar school. The fact that amongst his Paduan masters was the abbe Cesarotti, whose version of Ossian had made that work highly popular in Italy, was not without influence on Foscolo's literary work. He was not a man of modern pseudo-Grecian studies, but a student of ancient Greek. His literary ambition revealed itself by the appearance in 1797 of his tragedy Tiziano—a production which obtained a certain degree of success. Foscolo, who, from causes not clearly explained, had changed his Christian name Niccolo to that of Ugo, now began to take an active part in the stormy political discussions which the fall of the republic of Venice had provoked. He was a prominent member of the national committees, and addressed an ode to Napoleon the liberator, expecting from the military successes of the French general, not merely the overthrow of the effete Venetian oligarchy, but the establishment of a free republican government.

The treaty of Campo Formio (11th Oct. 1797), by which Napoleon handed Venice over to the Austrians, gave a rude shock to Foscolo, but did not quite destroy his hopes. The state of mind produced by that shock is reflected in the Letters of Jacopo Ortis (1798), a species of political Werther,—for the hero of Foscolo embodies the mental sufferings and suicide of an undeceived Italian patriot just as the hero of Goethe's places before us the too delicate sensitiveness embittering and at last cutting short the life of a private German scholar. The story of Foscolo, like that of Goethe, had a groundwork of melancholy fact. Jacopo Ortis had been a real personage; he was a young student of Padua, and committed suicide there under circumstances akin to those described by Foscolo. At this period Foscolo's mind appears to have been only too familiar with the thought of suicide. Cato and the many classical examples of self-destruction scattered through the pages of Plutarch appealed to the imaginations of young Italian patriots as they had done in France to those of the heroes and heroines of the Girondin. In the case of Foscolo, as in that of Goethe, the effect produced on the writer's mind by the composition of the work seems to have been beneficial. He had seen the ideal of a great national future rudely shattered; but he did not despair of his country, and sought relief in now turning to gaze on the ideal of a great national poet. At Milan, whither he repaired after the fall of Venice, he was engaged in other literary pursuits besides the composition of Ortis. The friendship formed there with the great poet Parini was ever afterwards remembered with pride and gratitude. The friendship formed with another celebrated Milanese poet soon gave place to a feeling of bitter enmity. Still hoping that his country would be freed by Napoleon, he served as a volunteer in the French army, took part in the battle of the Trebbia and the siege of Genoa, was wounded and made prisoner. When released he returned to Milan, and there gave the last touches to his Ortis, published a translation of and commentary upon Callimachus, commenced a version of the Iliad, and began his translation of Sterne's Sentimental Journey. The result of a memorandum prepared for Lyons, where, along with other Italian delegates, he was to have laid before Napoleon the state of Italy, only proved that the views cherished by him for his
FOSSO—FOSSOMBRONE 731

country were too bold to be even submitted to the dictator of France. The year 1807 witnessed the appearance of his Carne sui nepoti, of which the entire spirit and language may be described as a sublime effort to seek refuge in the past from the misery of the present and the darkness of the future. The mighty dead are summoned from their tombs, as ages before they had been in the masterpieces of Greek oratory, to fight again the battles of their country. The inaugural lecture on the origin and duty of literature, delivered by Foscolo in January 1809 when appointed to the chair of Italian eloquence at Pavia, was conceived in the same spirit. In this lecture Foscolo urged the youth of his country to study the ancient traditions, but in their relation to individual and national life and growth. The sensation produced by this lecture had no slight share in provoking the decree of Napoleon by which the chair of national eloquence was abolished in all the Italian universities. Soon afterwards Foscolo’s tragedy of Ajax was represented but with little success at Milan, and its supposed allusions to Napoleon rendering the author an object of suspicion, he was forced to remove from Milan to Tuscany. The chief fruits of his stay in Florence are the tragedy of Rodelot, an unfinished revision of his Ode to the City of God, and the completion of his work of the Sentimental Journey (1813). His version of Sterne is an important feature in his personal history. When serving with the French he had been at the Boulogne camp, and had traversed much of the ground gone over by Yorick; and in his memoir of Didimo Chierico, to whom the version is ascribed, he throws much curios light on his own character. He returned to Milan in 1813, until the entry of the Austrians; thence he passed into Switzerland, where he wrote a fierce satire in Latin on his political and literary opponents; and finally he sought the shores of England at the close of 1816.

During the eleven years passed by Foscolo in London, until his death there, he enjoyed all the social distinction which the most brilliant circles of the English capital confer on foreigners of political and literary renown, and experienced all the misery which follows on a disregard of the first conditions of domestic economy. His contributions to the Edinburgh and Quarterly Reviews, his dissertations in Italian on the text of Dante and Boccaccio, and still more his English essays on Petrarch, of which the value was enhanced by Lady Dacre’s admirable translations, gave him firm hold on some of Petrarch’s finest poems, heightened his own fame, and made him a man of letters. But his want of care and forethought in pecuniary matters involved him in much embarrassment, and at last consigned him to a prison; and when released he felt bitterly the change in his social position, and the coldness now shown to him by many whom he had been accustomed to regard as friends.

His general bearing in society—if we may accept on this point the testimony of so keen an observer and so tolerant a man as Sir Walter Scott—had unhappily not been such as to gain and retain lasting friendships. He died at Turnham Green on the 10th of October 1827. Forty-four years after his death, in 1871, his remains were brought to Florence, and with all the pride, pomp and circumstance of a great national mourning, found their final resting-place beside the monuments of Macchiaveli and Aliieri, of Michelangelo and Galileo, in Italy’s Westminster Abbey, the church of Santa Croce. To that solemn national tribute Foscolo was fully entitled. For the originality of his thoughts and the splendour of his diction his country honours him as a great classic author. He had assigned to the literature of his nation higher aims than any which it previously recognized. With all his defects of character, and through all his vicissitudes of fortune, he was always a sincere and courageous patriot.

Ample materials for the study of Foscolo’s character and career may be found in the complete series of his works published in Florence by Le Monnier. The series consists of Prose letterarie, (4 vols., 1850); Epistolario (3 vols., 1854); Prato politiche (1 vol. 1855); Poesie (1 vol. 1856); Lettere a Oriis (1 vol. 1858); Saggi di critica storico-letteraria (1st vol. 1859; 2nd vol. 1862). To this series must be added the very interesting work published at Leghorn in 1798, Lettere inedite del Foscolo, del Giordani, e della Signora di Stati, a Vincenzo Monti. The work published at Florence in the summer of 1878, Vida di Ugo Foscolo, di Dellegrino Artusi, throws much doubt on the genuineness of the text in Foscolo’s writings as given in the complete Florence edition, whilst it furnishes some curious and original illustrations of Foscolo’s familiarity with the English language.

FOSS, EDWARD (1787–1879), English lawyer and biographer, was born in London on the 16th of October 1875. He was a solicitor by profession, and on his retirement from practice in 1829, he devoted himself to the study of legal antiquities. His Judges of England (9 vols., 1838–1846) is a standard work, characterized by accuracy and extensive research. Biographia Juridica, a Biographical Dictionary of English Judges, appeared shortly after his death. He assisted in founding the Incorporated Law Society, of which he was president in 1842 and 1843. He died of apoplexy on the 27th of July 1879.

FOSSANO, a town and episcopal see of Piedmont, Italy, in the province of Cuneo, 15 m. N.E. of it by rail, 1180 ft. above sea-level. Pop. (1901) 7606 (town), 1875 (commune). It has an imposing castle with four towers, begun by Filippo d’Acaia in 1314. The cathedral was reconstructed at the end of the 18th century. The place began to acquire some importance in the 13th century. It appears as a commune in 1237, but in 1251 had to yield to Asti. It finally surrendered in 1314 to Filippo d’Acaia, whose successor handed it over to the house of Savoy. It lies on the main line from Turin to Cuneo, and has a branch line to Mondovì.

FOSSANUOVA, an abbey of Italy, in the province of Rome, near the railway station of Sonnino, 64 m. S.E. of Rome. It is the finest example of a Cistercian abbey, and of the Burgundian Early Gothic style, in Italy, and dates from the end of the 12th to the end of the 13th century. The church (1187–1208) is closely similar to that of Casamari. The other conventual buildings are also noteworthy. Thomas Aquinas died here in 1274.

FOSSE (or Foss) WAY, the Early English name of a Roman road or series of roads in Britain, used later by the English, running from Lincoln by Leicester and Bath to Exeter. Almost all the Roman line is still in use as modern road or lane. It passes from Lincoln through Newark and Leicester (the Roman Rotae) to High Cross (Feonume), where it intersects Walling Street at a point often called “the centre of England.” Hence it crosses to Melton-Mowbray, Crewesden, Bath and Helvellyn, crosses the hills near Chard, Axminster and Honiton, and enters Exeter. Antiquaries have taken it farther, usually to Totnes, but without warrant. (See further under ERMINE STREET.) (F. J. H.)

FOSSICK (probably an English dialectical expression, meaning fussy or troublesome), a term applied by the gold diggers of Australia to the search for gold by solitary individuals, in untutored localities or in abandoned diggings. A “fossicker,” or pocket miner, is one who buys up the right to search old claims, in the hope of finding gold overlooked by previous diggers.

FOSSOMBRONE (anc. Forum Sempronii), a town and episcopal see of the Marches, Italy, in the province of Pesaro and Urbino, 11 m. E.S.E. of the latter by road, 304 ft. above sea-level. Pop. (1901) town, 7531, commune, 10,847. The town is situated in the valley of the Metauro, in the centre of fine scenery, at the meeting-point of roads to Pano, to the Furlo pass and Fossato di Vico (the ancient Via Flaminia), to Urbino and to Sinigaglia, the last crossing the river by a fine bridge. The cathedral, rebuilt in 1772–1784, contains the chief work of the sculptor Domenico Rosselli; Rosmini Romano, a richly sculptured arca of 1480. S. Francesco has a lunette by him over the portal. The library, founded by a nephew of Cardinal Passionei, contains some antiquities. Above the town is a medieval castle. There is a considerable trade in silk.

The ancient Forum Sempronii lay about 2 m. to the N.E. at S. Martino al Piano, where remains still exist. It was a station on the Via Flaminia and a municipium. The date of its foundation is not known. Excavations in 1879–1886 led to the discovery of a house and of other buildings on the ancient road (A.)
Fossombroni, Vittorio, Count (1754-1844), Tuscan statesman and mathematician, was born at Arezzo. He was educated at the University of Pisa, where he devoted himself particularly to mathematics. He obtained an official appointment in Tuscany in 1782, and twelve years later was entrusted by the grand duke with the direction of the works for the drainage of the Val di Chiana, on which subject he had published a treatise in 1789. In 1796 he was made minister for foreign affairs, but on the French occupation of Tuscany in 1799 he fled to Sicily. On the erection of the grand duchy into the ephemeral kingdom of Etruria, under the queen-regent Maria Luisa, he was appointed president of the commission of finance. In 1809 he went to Paris as one of the senators for Tuscany to pay homage to Napoleon. He was made president of the legislative commission on the restoration of the grand duke Ferdinand III. in 1814, and subsequently prime minister, which position he retained under the grand duke Leopold II. His administration, which was only terminated by his death, greatly contributed to promote the well-being of the country. He was the real master of Tuscany, and the bases of his rule were equality of all subjects before the law, honesty in the administration of justice and toleration of opinion, but he totally neglected the moral improvement of the people. At the age of seventy-eight he married, and twelve years afterwards died, in 1844.

Fossombroni, A. von Reumont, Geschichte Toscana unter dem Hause Lobkowitz-Habsburg (Gottingen, 1877); Zoli, Storia civile della Toscana (Florence, 1860-1853); Galeotti, Delle Leggi e dell' amministrazione della Toscana (Florence, 1847); Baldasseroni, Leopoldo II. (Florence, 1871); see also under Capponi, Gino; Ferdinand III., of Tuscany, and Leopold II., of Tuscany. (L. V.)

Foster, Sir Clement Le Neve (1824-1904). English geologist and mineralogist, the second son of Peter Le Neve Foster (for many years secretary of the Society of Arts), was born at Camberwell on the 23rd of March 1841. After receiving his early education at Boulogne and Amiens, he studied successively at the Royal School of Mines in London and at the mining college of Freiburg in Saxony. In 1860 he joined the Geological Survey in England, working in the Wealden area and afterwards in Derbyshire. Conjointly with William Topley (1844-1894) he communicated to the Geological Society of London in 1865 the now classic paper "On the superficial deposits of the Valley of the Medway, with remarks on the Denudation of the Weald." In this paper the sculpturing of the Wealden area by rain and rivers was ably advocated. Retiring from the Geological Survey in 1865, Foster devoted his attention to mineralogy and mining in Cornwall, Egypt and Venezuela. In 1872 he was appointed an inspector of mines under the home office for the S.W. of England, and in 1886 he was transferred to the N. Wales district. In 1890 he was appointed professor of mining at the Royal College of Science and he held this post until the close of his life. His later work is embodied largely in the reports of mines and quarries issued annually by the home office. He was distinguished for his extensive scientific and practical knowledge of metallic mining and stone quarrying. He was elected F.R.S. in 1892 and was knighted in 1903. While investigating the cause of a mining disaster in the Isle of Man in 1897 his constitution suffered much injury from carbonic oxide gas, and he never fully recovered from the effects. He died in London on April 4th 1904. He published: On the Stone Mining, 1894 (ed. 5, 1904); and The Elements of Mining and Quarrying, 1903.

Foster, George Eulas (1847- ), Canadian politician and financier, was born in New Brunswick on the 3rd of September 1847, of U.E. Loyalist descent. After a brilliant university career at the university of Brunswick, at Edinburgh and Heidelberg, he returned to Canada and taught in various local schools, eventually becoming professor of classics and history in the local university. In 1883 he became Conservative member for King's County, N.B., in the Dominion parliament, and in 1885 entered the cabinet of Sir John Macdonald as minister of marine and fisheries; in 1888 he became minister of finance, which position he held till the defeat of his party in 1896. A careful and even brilliant financier, and a keen debater, he became known as a strong believer in protection for Canadian industries and in preferential trade within the British empire.

Foster, John (1770-1853), English author and dissenting minister, generally known as the "Essayist," was born in a small farmhouse near Halifax, Yorkshire, on the 17th of September 1770. Partly from constitutional causes, but partly also from the want of proper companions, as well as from the grave and severe habits of his parents, his earlier years were passed in a somewhat gloomy and sombre atmosphere, which was never afterwards wholly dissipated. His youthful energy, finding no proper outlet, developed within him a tendency to morbid intensity of thought and feeling; and, according to his own testimony, before he was twelve years old he was possessed of a "painful sense of an awkward but entire individuality." The small income accruing to Foster's parents from their farm they supplemented by weaving, and at an early age he began to assist them by spinning wool by the hand wheel, and in the fourteenth year of his age, having duties as a "child," he had the "feelings of a foreigner in the place"; and though he performed his monotonous task with conscientious diligence, he succeeded so indifferently in fixing his wandering thoughts upon it that his work never without difficulty passed the ordeal of inspection. He had acquired a great taste for reading, to gratify which he sometimes shut himself up alone in a barn, afterwards working at his loom "like a horse," to make up for lost time. He had also at this period a passion for making pictures with a pen. Shortly after this he went to Bath for the summer, and the result of his stay was "the idea of the Baptist church at Hebden Bridge, with which his parents were connected; and with the view of preparing himself for the ministerial office he began about the same time to attend a seminary at Brearley Hall conducted by his pastor Dr Fawcett. After remaining three years at Brearley Hall he was admitted to the Baptist College, Bristol, and on finishing his course of study at this institution he obtained an engagement at Newcastle-on-Tyne, where he preached to an audience of less than a hundred persons, in a small and dingy room situated near the river at the top of a flight of steps called Puthill Stairs. At Newcastle he only had three hearers at his preaching. Eagerly desiring to be a valuable to the Baptist church at Chichester, but though he applied himself with more earnestness and perseverance than formerly to the discharge of his ministerial duties, his efforts produced little apparent impression, and the gradual diminution of his hearers necessitated his resignation. After employing himself for a few months at Battersea in the instruction of twenty African youths brought to England by Zachary Macanlay, with the view of having them trained to aid as missionaries to their fellow-countrymen, he in 1800 accepted the charge of a small congregation at Downend, Bristol, where he continued about four years. In 1804, chiefly through the recommendation of Robert Hall, he became pastor of a congregation at Frome, but a swelling in the thyroid gland compelled him in 1806 to resign his charge. In the same year he published the volume of Essays on which his literary fame most largely if not mainly rests. The whole work was written in the form of letters addressed to the lady who afterwards married, and consist of four papers,—"On a Man writing Memoirs of himself"; "On Decision of Character"; "On the Application of the Epithet Romantic"; and "On some Causes by which Evangelical Religion has been rendered unacceptable to Men of Cultivated Taste." The success of this work was immediate, and was so considerable that on resigning his charge he determined to adopt literature as his profession.
FOSTER, SIR MICHAEL—FOSTORIA

The Edict Review was the only periodical with which he established a connexion; but his contributions to that journal, which were begun in 1807, number no fewer than 185 articles. On his marriage in May 1808 he removed to Bourn-on-the-Water, a small village in Gloucestershire, where he remained till 1817, when he returned to Downend and resumed his duties to his old congregation. Here he published in 1820 his Essay on Popular Ignorance, which was the enlargement of a sermon originally preached on behalf of the British and Foreign School Society. In 1821 he removed to Stapleton near Bristol, and in 1822 he began a series of fortnightly lectures at Broadmead chapel, Bristol, and in 1825 he afterwards administered as a member of the Wesleyan society. At Robert Hall at Bristol this service was discontinued, as in such circumstances it appeared to Foster to be "altogether superfluous and even bordering on impertinent." The health of Foster during the later years of his life was somewhat infirm, the result chiefly of the toil and effort of literary composition; and the death of his only son, his wife and the greater number of his most intimate friends combined with his bodily ailments to lend additional sombreness to his manner of regarding the events and arrangements of the present world—the visage of death "being almost his "one remaining luminary." He died at his parsonage house on the 4th of October 1864.

The cast of Foster's mind was meditative and reflective rather than logical or metaphysical, and though holding moderately Calvinistic views, his language even in preaching very seldom took the mould of theological forms. Though always retaining his connexion with the Baptist denomination, the evils resulting from organized religious communities seemed to him so great that he came to be "strongly of opinion that churches are useless and mischievous institutions, and the sooner they are dissolved the better." The only Christian observances which he regarded as of any importance were his connexion with worship and the Lord's Supper, and it so happened that he never administered the ordinance of baptism. His cast of thought is largely coloured by a constant reference to the "endless future." He was a firm believer in supernatural appearances, and cherished a longing hope that a ray of light from the other world might sometimes in this way be vouchsafed to mortals. As a writer he was most painstaking and laborious in his choice of diction, and his style has its natural consequent defects, though the result is eloquent in its way.

Besides the works already alluded to, Foster was the author of _Life of H. B. Ives_ (1829); _Life of David Brainerd_ (1811); _Introductory Essay_ to Doddridge's _Rise and Progress of Religion_ (1829); _Observations on Mr Hall's Character as a Preacher_ prefixed to the collected edition of his sermons (1800); _Introduction to a pamphlet on the Scopolium_; _Marchman on the Scaramouche Missionaries_; several political letters to the Morning Chronicle, and contributions to the Edict Review, published posthumously in 2 vols., 1844. _His Life and Correspondence_, edited by J. E. Ryland, was published in 1846.

FOSTER, SIR MICHAEL (1836-1907), English physician, was born at Huntingdon on the 5th of March 1836. After graduating in medicine at London University in 1859, he began to practise in his native town, but in 1865 he returned to London as teacher of practical physiology at University College, where two years afterwards he became professor. In 1870 he was appointed by Trinity College, Cambridge, to its praetorship in physiology, and thirteen years later he became the first occupant of the newly-created chair of physiology in the university, holding it till 1903. He excelled as a teacher and administrator, and had a very large share in the organization and development of the Cambridge biological school. From 1881 to 1903 he was one of the signers of the Royal Society, and in that capacity exercised a wide influence on the study of biology in Great Britain. In 1899 he was created K.C.B., and served as president of the British Association at its meeting at Dover. In the following year he was elected to represent the university of London in parliament. Though returned as a Unionist, his political action was not to be dictated by party considerations, and he gravitated towards Liberalism; but he played no prominent part in parliament and at the election of 1906 was defeated. His chief writings were a _Textbook of Physiology_ (1876), which became a standard work, and _Lectures on the History of Physiology in the 16th, 17th and 18th Centuries_ (1901), which consisted of lectures delivered at the Cooper Medical College, San Francisco, in 1900. He died suddenly in London on the 29th of January 1907.

FOSTER, MYLES BIRKET (1825-1899), English painter, was born at North Shields. At the age of sixteen he entered the workshop of Ebenezer Landells, a wood engraver, with whom he worked for six years as an illustrative draughtsman, devoting himself mainly to landscape. During the succeeding fifteen years he became famous as a prolific and accomplished illustrator, but in 1886 he abandoned illustration for painting, and gained wide popularity by his pictures, chiefly in water colours, of landscapes and rustic subjects, with figures, mainly of children. He was elected in 1860 associate and in 1862 full member of the Royal Society of Painters in Water Colours. His work is memorable for its delicacy and minute finish, and for its daintiness and pleasantness of sentiment.

See Birket Foster, _His Life and Work_ (extra number of the Art Journal) by Marcus B. Huish (1890), an interesting sketch; and _Birket Foster, R.W.S._ by H. M. Cundall (London, 1906), a very complete and fully illustrated biography.

FOSTER, STEPHEN COLLINS (1826-1864), American song and ballad writer, was born near Pittsburg, Pennsylvania, on the 4th of July 1826. He was the youngest child of a merchant of Irish descent who became a member of the state legislature and was related by marriage to President Buchanan. Stephen early showed talent for music, and played upon the fife, the guitar and the banjo; he also acquired a fair knowledge of French and German. He was sent to school in Towanda, Pennsylvania, and later to Athens, Pennsylvania, and when thirteen years old he wrote the song "Sadly to Mine Heart Appealing." At sixteen years old he wrote "Old Thay Lattice," and at seventeen he entered his brother's business house, Cincinnati, Ohio, where he remained about three years, composing meanwhile such popular pieces as "Old Uncle Ned," "O Susannah!" and others. He then adopted song-writing as a profession. His chief successes were songs written for the negro melodists or Christy minstrels. Besides those mentioned the following attained great popularity: "Nelly was a Lady," "Old Kentucky Home," "Old Folks at Home," "Massa's in de Cold, Cold Ground," &c. &c. Many other songs, the composer received considerable sums, "Old Folks at Home," bringing him 500 dollars. For most of his songs Foster wrote both songs and music. In 1850 he married and moved to New York, but soon returned to Pittsburg. His reputation rests chiefly on his negro melodies, many of which have been popular on both sides of the Atlantic and sung in many tongues. "Old Black Joe," the last of these negro melodies, appeared in 1861. His later songs were sentimental ballads. Among these are "Old Dog Tray," "Gentle Annie," "Willie, we have missed you," &c. His "Come where my Love lies Dreaming" is a well-known vocal quartet. Although as a musician and composer Foster has little claim to high rank, his song-writing gives him a prominent place in the modern developments of popular music. He died at New York on the 13th of January 1864.

FOSTORIA, a city, partly in Seneca, partly in Hancock, and partly in Wood county, Ohio, U.S.A., 35 m. S. by E. of Toledo. Pop. (1890) 7705; (1900) 7730 (584 foreign-born); (1910) 9597. It is served by the Baltimore & Ohio, the New York, Chicago & St Louis, the Ohio Central, the Lake Erie & Western, and the Hocking Valley railways, and by two interurban electric lines. The city is situated in a well cultivated region, and in the vicinity. Among the city's manufactures are glass, flour, planing mill products, brass and iron, carriages, barrels, incandescent lamps, carbons, wire nails and fences, automobile engines and parts, railway torpedoes and muslin underwear. The waterworks are owned and operated by the municipality. In 1852, upon the coming of the first settlers, two towns, Rome and Risdon, were laid out on the site of what is now Fostoria. A bitter rivalry arose between them, but they were finally united under one government, and the city thus formed was named in
FOUGÈRE—FOUCHÉ

honour of Charles W. Foster, whose son Charles Foster (1789–
1864), governor of the state from 1830 to 1834, and secretary of
the United States treasury from 1851 to 1853, did much to pro-
mote its growth. Fosteria was chartered as a city in 1854.

FOUGÈRE, Jean Bernard Léon (1810–1868), French
physicist, was the son of a publisher at Paris, where he was born
on the 18th of September 1810. After an education received
chiefly at home, he studied medicine, which, however, he speedily
abandoned for physical science, the improvement of L. J. M.
Daguerre’s photogenic processes being the object to which
he first directed his attention. During three years he was experi-
mental assistant to Alfred Dedron (1801–1878) in his course
of lectures on microscopic anatomy. With A. H. L. Fizeau he
carried on a series of investigations on the intensity of the
light of the sun, as compared with that of carbon in the electric arc,
and of lime in the flame of the oxyhydrogen blowpipe; on the
interference of heat rays, and of light rays differing greatly in
lengths of path; and on the chromatic polarization of light.
In 1849 he contributed to the Comptes Rendus a description of
an electromagnetic regulator for the electric arc lamp, and,
in conjunction with H. V. Regnault, a paper on binocular vision.
By the use of a revolving mirror similar to that used by Sir
Charles Wheatstone for measuring the rapidity of electric
currents, he was enabled in 1850 to demonstrate the greater
velocity of light in air than in water, and to establish that the
velocity of light in different media is inversely as the refractive
indices of the media. For his demonstration in 1851 of the
diurnal motion of the earth by the rotation of the plane of oscilla-
tion of a freely suspended, long and heavy pendulum exhibited
by him at the Pantheon in Paris, and again in the following
year by means of his invention the gyroscope, he received the
Copley medal of the Royal Society in 1855, and in the same year
he was made physical assistant in the important observatory at
Paris. In September of that year he discovered that the force
required for the rotation of a copper disk becomes greater when
it is made to rotate with its rim between the poles of a magnet,
the disk at the same time becoming heated by the eddy or
"Foucault currents" induced in its metal. Foucault invented in
1857 the polarizer which bears his name, and in the succeeding
year devised a method of giving to the speculum of reflecting
telescopes the form of a spheroid or a paraboloid of revolution.
With Wheatstone’s revolving mirror he in 1862 determined
the absolute velocity of light to be 298,000 kilometres (about
185,000 m.), a second, or 10,000 kilom. less than that obtained by previous
experimenters. He was created in that year a member of the
French Academy of Sciences and an officer of the Legion of Honour,
in 1864 a foreign member of the Royal Society of London,
and next year a member of the mechanical section of the
Institute. In 1865 appeared his papers on a modification of
Watt’s governor, upon which he had for some time been exper-
imenting with a view to making its period of revolution constant,
and on a new apparatus for regulating the electric light; and
in the following year (Compt. rend. iii.) he showed how, by
the deposition of a transparently thin film of silver on the outer side
of the object glass of a telescope, the sun could be viewed without
the slightest impression of light. Foucault died of paralysis
on the 11th of February 1868 at Paris. From the year 1845
he edited the scientific portion of the Journal des Débats.
His chief scientific papers are to be found in the Comptes Rendus,
1847–1860.

xxvii. (1869), pp. lxxiii.–lxxxiv.; Lissajous, Notice historique sur la
vie et les travaux de Léon Foucault (Paris, 1875).

FOUCHÉ, Joseph, Duke of Otranto (1759–1820), French
statesman, was born in a small village near Nantes on the 21st
of May 1759. His father, a sea-faring man, destined him for
the sea; but the weakness of his frame and the precocity of his
talents soon caused this idea to be given up. He was educated
at the college of the Oratorians at Nantes, and showed marked
aptitude for studies both literary and scientific. Desiring to
enter the teaching profession he was sent to an institution kept
by brethren of the same order at Paris. There also he made
rapid progress, and soon entered upon tutorial duties at the
colleges of Niort, Saumur, Vendôme, Juilly and Arras. At Arras
he had some dealings with Robespierre at the time of the begin-
nings of the French Revolution (1789).

In October 1790 he was transferred by the Oratorians to
their college at Nantes, owing to irregularities due to his zeal
for revolutionary principles; but at Nantes he showed even
more democratic fervour. His abilities and the zeal with which
he espoused the most subversive notions brought him into
favour with the populace at Nantes; he became a leading
member of the local Jacobin club; and on the dissolution of
the college of the Oratorians at Nantes in May 1792. Fouché gave
up all connexion with the church, whose major vows he had
taken. After the downfall of the monarchy on the 10th of
August 1792, he was elected as deputy for the department of
the Lower Loire to the National Convention which met at the
autumnal equinox and proclaimed the republic. The literary
and pedagogic sympathies of Fouché at first brought him into
touch with Condorcet and the party, or group, of the Girondists;
but their vacillation at the time of the trial and execution of
Louis XVI. (December 1792–January 21, 1793) led him to
espouse the cause of the Jacobins, the less scrupulous and more
thoroughgoing champions of revolutionary doctrine. On the
question of the execution of the king, Fouché, after some pre-
liminary hesitations, expressed himself with the utmost vigour
in favour of immediate execution, and denounced those who
"wavered before the shadow of a king."

The crisis which resulted from the declaration of war by the
Convention against England and Holland (Feb. 1, 1793), and
a little later against Spain, brought Fouché into notoriety as
one of the foremost of the Jacobinical fanatics who then held
power at Paris. While the armies of the first coalition threatened
the north-eastern frontier of France, a revolt of the royalist peasants
of Brittany and in Vendée menaced the Convention on the west.
That body deposed Fouché with a colleague, Villers, to proceed
FOUCHÉ

735
to the west as commissioners invested with almost dictatorial powers for the crushing of the revolt of "the whites." The vigour with which he carried out these duties earned him other work, and he soon held the post of commissioner of the republic in the department of the Nièvre. Together with Chaumette, he helped to initiate the atheistical movement, the founders of which in the autumn of 1793 began to aim at the extinction of Christianity in France. In the department of the Nièvre he ransacked the churches, sent their spoils to the treasury and established the cult of the goddess of Reason. Over the cemeteries, he ordered these words to be inscribed: "Death is an eternal sleep." He also waged war against luxury and wealth, and desired to abolish the use of money. The new cult was inaugurated at Paris at Notre Dame by the strange orgy known as "The Festival of Reason" (November 10, 1793).

Fouché then proceeded to Lyons to execute the vengeance of the Convention on that city, which had revolted against the new Jacobin tyranny. Precluding his work by legal remarkability for its obscene parody of religious rites, he then, along with his colleague, Collot d'Hèrbois, set the guillotine and cannon to work with a rigour which made his name odious. Modern research, however, proves that at the close of those horrors Fouché exercised a moderating influence. Outwardly his conduct was marked by the utmost rigour, and on his return to Paris early in April 1794, he thus characterised his policy: "The blood of criminals fertilises the soil of liberty and establishes power on sure foundations." By that time Robespierre had struck down the other leaders of the atheistical party; but early in June 1794, at the time of the "Festival of the Supreme Being," Fouché ventured to mock at the theistic revival which Robespierre then inaugurated. Sharp passages of arms took place between them, and Robespierre procured the election of Fouché from the Jacobin Club (July 14, 1794). Fouché, however, was working with his customary skill and energy, and along with Tallien and others, managed to effect the overthrow of the theistic dictator on Thermidor 10 (July 28), 1794. The ensuing reaction in favour of more merciful methods of government threatened to sweep away the group of Terrorists who had been mainly instrumental in carrying through the coup d'état of Theodor; but, thanks largely to the skill of Fouché in intrigue, they managed for a time to keep at the head of affairs. Discords, however, crept in which left him for a time almost isolated, and it needed all his ability to withstand the attacks of the moderates. A vigorous attack on him by Boissy d'Anglas, on the 9th of August 1795, caused him to be arrested, but the troubles which ensued in Vendée avverted the doom that seemed to be pending; and he owed his release to the amnesty which was passed on the proclamation of the new constitution of the year 1795.

In the ensuing period, known as that of the Directory (1795-1799), Fouché remained at first in obscurity, but the relations which he had with the communists, once headed by Chaumette and now by François N. ("Graecus") Babeuf (q.v.), helped him to rise once more. He is said to have betrayed to the director Barras the secret of the strange plot which Babeuf and a few accomplices hatched in the year 1796; but recent research has tended to throw doubt on the assertion. His rise from poverty was slow, but in 1797 he gained an appointment for the supply of military matériel, which offered opportunities direct and indirect. After offering his services to the royalists, whose movement was then gathering force, he again decided to support the Jacobins and the director Barras (q.v.). In the coup d'état of Fructidor 1797 he made himself serviceable to Barras, who in 1798 appointed him to be French ambassador to the Cisalpine republic. At Milan he carried matters with so high a hand against the Gallophobes of that government that his actions were disapproved and he himself was removed; but in the confused state in which matters then were, he was able for a time to hold his own and to intrigue successfully against his successor. Early in 1799 he returned to Paris, and after a brief tenure of office as ambassador at The Hague, he became minister of police at Paris (July 20, 1799). The newly elected director, Sève (q.v.), was then in the ascendent and desired to curb the excesses of the Jacobins, who had recently reopened their club. Fouché, casting consistency to the winds, closed the Jacobins club in a manner at once daring and clever. Thereupon he hunted down the pamphleteers and editors, whether Jacobins or royalists, who were obnoxious to the government, so that at the time of the return of Bonaparte from Egypt (October 1799) the Jacobins were one of the most powerful men in France.

Knowing well the unpopularity of the director, Fouché lent himself to the schemes of Bonaparte and Sève for their overthrow. His activity in furthering the coup d'état of Brumaire 18-19 (November 9-10), 1799, procured him the favour of Bonaparte, who kept him in office (v. Napoleon I). In the ensuing period of the Consulate (1799-1804) Fouché behaved with the utmost adroitness. While curbing the royalists and extreme Jacobins who at first alone opposed Bonaparte, Fouché was careful to temper as far as possible the arbitrary actions of the new master of France. In this difficult task he acquitted himself with so much skill as to earn at times the gratitude of even the royalists. Thus, while countermarking a foolish intrigue of theirs in which the duchesse de Guiche was the chief agent, Fouché took care that she should escape. Equally skilful was his action in the affair of the so-called Aréna-Cercaci plot, in which the agents provocateurs of the police were believed to have played a sinister part. The chief "conspirators" were easily ensnared and were executed when the affair of Nivôse (December 1800) enabled Bonaparte to act with rigour. This far more serious attempt (in which royalist conspirators exploded at the Batignolles road, the condemned prisoners, after the cell had been destroyed, made an escape) was soon seen by Fouché to be the work of the royalists; and when the First Consul, eager to entrap the still formidable Jacobins, sought to fasten the blame on them, Fouché firmly declared that he would not only assert but would prove that the outrage was the work of royalists. All his efforts, however, failed to avert the punishment which Bonaparte was resolved to inflict on the leading Jacobins. In other matters (especially in that known as the Plot of the Placards in the spring of 1802) Fouché was thought to have secured the Jacobins concerned from the vengeance of the First Consul. In any case the latter resolved to rid himself of a man who had too much power and too much skill in intrigue to be desirable as a subordinate. On the proclamation of Bonaparte as First Consul for life (August 1, 1802) Fouché was deprived of his office; but the blow was softened by the suppression of the ministry of police and by the attribution of most of its duties to an extended ministry of justice. Fouché also became a senator and received half of the reserve funds of the police which had accumulated during his tenure of office. He continued, however, to intrigue through his spies, whose information was so superior to that of the new minister of police as to render great services to Napoleon at the time of the Cadoudal-Pichegru conspiracy (February-March 1804).

As a result Napoleon, now emperor, brought back Fouché to the re-constituted ministry of police (July 1804); he also later on entrusted to him that of the interior. His work was no less important than at the time of the Consulate. His police agents were ubiquitous, and the terror which Napoleon and Fouché inspired, owing to their proven ability to benefit by plots, partly accounts for the absence of conspiracies after 1804. After Austerlitz (December 1805) Fouché uttered the motto of the occasion: "Sire, Austerlitz has shattered the old aristocracy; the boulevard St Germain no longer conspires."

That Napoleon retained some feeling of distrust, or even of fear, of Fouché was proved by his conduct in the early days of 1808. While engaged in the campaign of Spain, the emperor heard rumours that Fouché and Talleyrand, once bitter enemies, were having interviews at Paris in which Murat, king of Naples, was concerned. At once the sensitive autocrat hurried to Paris, but found nothing to incriminate Fouché. In that year Fouché received the title of duke of Orleans. During the absence of Napoleon in Austria in the campaign of 1809, the British Walcheren expedition threatened for a time the safety of
Antwerp. Fouché thereupon issued an order to the prefects of the northern departments of the empire for the mobilization of 60,000 National Guards. He added to the order a statement in which occurred the words: "Let us prove to Europe that although the genius of Napoleon can throw lustre on France, his presence is not necessary to enable us to repulse the enemy." The emperor's approval of the measure was no less marked than his disapproval of the words just quoted. The next months brought further causes of friction between emperor and minister. The latter, knowing the desire of his master for peace at the close of the year 1809, undertook on his own account to make secret overtures to the British ministry. A little later Napoleon opened negotiations and found that Fouché had forestalled him. His rage against his minister was extreme, and on the 3rd of June 1810 he dismissed him from his office. However, as it was not the emperor's custom completely to disgrace a man who might again be useful, Fouché received the governorship of Rouen.

He went thither, not as governor but as fugitive, for on receiving the emperor's order to give up certain important documents of his former ministry, he handed over only a few, declaring that the rest were destroyed. At this the emperor's anger burst forth again, and Fouché on learning, after his arrival at Florence, that the storm was still raging at Paris, prepared to sail to the United States. Compelled, however, by stress of weather and sickness to put back again, he found a mediator in Elisa Bonaparte, grand duchess of Tuscany, thanks to whom he was allowed to settle at Aix and finally to return to his domain at Château-Céleyran.

In 1813 he sought vainly to turn Napoleon from the projected invasion of Russia; and on the return of the emperor in haste from Smorgoni to Paris at the close of that year, the ex-minister of police was suspected of complicity in the conspiracy of General Malet, which came so strangely near to success. From this suspicion Fouché cleared himself and gave the emperor useful advice concerning internal affairs and the diplomatic situation. Nevertheless, the emperor, still distrustful of the arch-intriguer, ordered him to undertake the government of the Illyrian provinces. On the break-up of the Napoleonic system in Germany in October 1813 Fouché was ordered to repair to Rome and thence to Naples, in order to watch the movements of Murat. Before Fouché arrived at Naples Murat threw off the mask and invaded the Roman territory, whereupon Fouché received orders to return to France. He arrived at Paris on the 10th of April 1814 at the time when Napoleon was being constrained by his marshals to abdicate.

The conduct of Fouché at this crisis was characteristic. As senator he advised the senate to send a deputation to the comte d'Artois, brother of Louis XVIII., with a view to a reconciliation between the monarchy and the nation. A little later he addressed to Napoleon, then at Elba, a letter begging him in the interests of peace and of France to withdraw to the United States. To the new sovereign Louis XVIII. he sent an appeal in favour of liberty and recommending the adoption of measures which would conciliate all interests. It was not successful, but Fouché remained un molested.

This was far from satisfying him, and when he found that there were no hopes of advancement, he entered into relations with conspirators who sought the overthrow of the Bourbon dynasty. Lafayette and Davout were concerned in the affair, but their refusal to take the course desired by Fouché and other bold spirits led to nothing being done. Soon Napoleon escaped from Elba and made his way in triumph to Paris. Shortly before his arrival at Paris (March 19, 1815) Louis XVIII. sent to Fouché an offer of the ministry of police, which he declined, saying, "It is too late; the only plan to adopt is to retreat." He then foiled an attempt of the royalists to arrest him, and on the 23rd of May he received for the third time the portfolio of police. That, however, proved to be only an act of entering into secret relations with Metternich at Vienna, his aim being then, as always, to prepare for all eventualities. Meanwhile he used all his powers to induce the emperor to popularise his rule, and he is said to have caused the insertion of the words "The sovereignty resides in the people; it is the source of power" in the declaration of the council of state. But the autocratic tendencies of Napoleon could scarcely be held in check, and Fouché seeing the fall of the emperor to be imminent, took measures to expedite it and secure his own interests. On the 22nd of June Napoleon abdicated for the second time, and Fouché was next day elected president of the commission which provisionally govern the country. He already was in touch with Louis XVIII., then at Ghent, and was given all the overtures of his agent at Paris. While ostensibly working for the recognition of Napoleon II., he facilitated the success of the Bourbon cause, and thus procured for himself a place in the ministry of Louis XVIII. Even his skill, however, was unequal to the task of conciliating hot-headed royalists who remembered his vote as regicide and his fanaticism as terrorist. He resigned office, and after acting for a brief space as ambassador at Dresden, he retired to Frangy. Finally he settled at Trieste, where he died on the 25th of December 1820. He had accumulated great wealth.

Marked at the outset by fanaticism, which, though cruel, was at least conscientious, Fouché's character deteriorated in and after the year 1794 into one of calculating cunning. The transition represented all that was worst in the life of France during the period of the Revolution and Empire. In Fouché the enthusiasm of the earlier period appeared as a cold, selfish and remorseless fanaticism; in him the bureaucracy of the period 1795-1799 and the autocracy of Napoleon found their ablest representative. Yet an intellectual pride prevented him sinking to the level of a mere intriguer. His relations with Napoleon were marked by a certain aloofness. He multiplied the means of resistance even to that irresistible autocrat, so that though removed from office, he was never wholly disgraced. Despised by all for his turgiversations, he nevertheless was sought by all on account of his cleverness. He repaid the contempt of his superiors and the adulation of his inferiors by a mask of impenetrable reserve or scorn. He sought for power and neglected no means to make himself serviceable to the party whose success appeared to be imminent. Yet, while appearing to be the servant of the victors, present or prospective, he never gave himself to any one party. In this versatility he resembles Talleyrand, of whom he was a coarse replica. Both professed, under all their shifts and turns, to be desirous of serving France. Talleyrand certainly did so in the sphere of diplomacy; Fouché may occasionally have done so in the sphere of intrigue.

Bibliography.—Fouché wrote some political pamphlets and reports, the most important of which are Preface au Journal (Paris, 1798); Réflexions sur l'éducation publique (1793); Rapport et projet de loi relatif aux collèges (1793); Rapport sur la situation de Commune (1793); Lettre aux préfets concernant les prisons, &c. (1801); also the letters of the chevalier de la Tour du Pégaz; and those of the duc de Wellington (1817). The best life of Fouché is that by L. Madelin, Fouché (2 vols., Paris, 1901). The so-called Fouché Memoirs are not genuine, but they were apparently compiled, at least in part, from notes written by Fouché, and are often valuable, though their account of events (e.g. of the negotiations of 1809-1810) is not seldom untrustworthy. For those negotiations see Coquelle, Histoire de l'Angleterre (Paris, 1903, Eng. trans., London, 1904). For the plots with which Fouché had to deal see E. Daudet, La Police et les Chouans sous le Consulat et l'Empire (Paris, 1895); P. M. Desmares, L'histoire de l'Empire, ou guerre entre la police française et les Chouans du Sud (Paris, 1886); E. Picard, Bonaparte et Murat (Paris, 1895); G. A. Thierry, Conspirateurs et gens de police; le complot de libelles (Paris, 1895) (Eng. trans., London, 1903); H. de Wailly, Rapport, Le Duc d'Enghien (Paris, 1888); E. Gerim, Les Conspirateurs militaires sous le Consulat et l'Empire (Paris, 1894). (J. H. K.)

FOUCHER, SIMON (1644-1696), French philosopher, was born at Dijon on the 1st of March 1644. He was the son of a merchant, and appears to have taken orders at a very early age. For some years he held the position of honorary canon at Dijon, but this he resigned in order to take up his residence in Paris. He graduated at the Sorbonne, and spent the remainder of his life in literary work in Paris, where he died on the 27th of April 1696. He was a man who could not prevent Foucher, when tribune of 1789, from being an opponent of Malebranche. His philosophical standpoint was one of scepticism in regard to external perception. He revived the old arguments of the Academy, and advanced them with much ingenuity against Malebranche's doctrine. Otherwise
his scepticism is subordinate to orthodox belief, the fundamental dogmas of the church seeming to him intuitively evident. His object was to reconcile his religious with his philosophical creed, and to remain a Christian without ceasing to be an academician. His writings against Malebranche were collected under the title *Dissertations sur la recherche de la vérité*, 1603.

**FOUCQUET, JEAN, or JEHAN** (c. 1415-1489). French painter, born at Tours, is the most representative and national French painter of the 15th century. Of his life little is known, but it is certain that he was in Italy about 1437, where he executed the portraits of the popes IV. and VII. After returning to France, whilst retaining his purely French sentiment, he graftcd the elements of the Tuscan style, which he had acquired during his sojourn in Italy, upon the style of the Van Eycks, which was the basis of early 15th-century French art, and thus became the founder of an important new school. He was court painter to Louis XI. Though his supreme excellence as an illuminator and miniaturist, of exquisite precision in the rendering of the finest detail, and his power of clear characterization in work on this minute scale, have long since procured him an eminent position in the art of his country, his importance as a painter was only recognized when his portraits and altarpieces were for the first time brought together from various parts of Europe in 1904, at the exhibition of the French Primitives held at the Bibliothèque Nationale in Paris. One of Fouquet’s most important paintings is the diptych, formerly at Notre Dame de Melun, of which one wing, depicting Agnes Sorel as the Virgin, is now at the Antwerp Museum and the other in the Berlin Gallery. The Louvre has his oil portraits of Charles VII., of Count Wilczek, and of Jouvencal de Ursins, besides a portrait drawing in crayon; whilst an authentic portrait from his brush is in the Liechtenstein collection. Far more numerous are his illuminated books and miniatures that have come down to us. The Bretano-Laroché collection at Frankfort contains forty miniatures from a Book of Hours, painted in 1461 for Étienne Chevallier who is portrayed by Fouquet on the Berlin wing of the Melun altarpiece. From Fouquet’s hand again are eleven out of the fourteen miniatures illustrating a translation of Josephus at the Bibliothèque Nationale. The second volume of this MS., unfortunately with only one of the original thirteen miniatures, was discovered and bought in 1903 by Mr Henry Yates Thompson, whose collection it contains. See *Oeuvres de Jehan Fouquet* (Curmer, Paris, 1886-1867); A. de Chameaux and P. Gauchery, *Oeuvres d’art exécutées pour le duc de Berry*; Facsimiles of two histories by Jean Fouquet from vols. i. and ii. of the *Academie des Arts* (London, 1902); Charles Blanc, *Histoire des peintres de toutes les écoles* (introduction); and Georges Lalencetre, *Jehan Fouquet* (Paris, 1902).

**FOUGÈRES,** a town of north-western France, capital of an arrondissement in the department of Ille-et-Vilaine, 30 m. N.E. of Rennes by rail. Pop. (1906) 21,847. Fougeres is built on the summit and slopes of a hill on the left bank of the Nançon, a tributary of the Couesnon. It was formerly one of the strongest places on the frontier towards Normandy, and it still preserves some portions of its medieval fortifications, notably a gateway of the 15th century known as the Porte St Sulpice. The castle, which is situated in the lower part of the town, directly overlooking the Nançon, is now a picturesque ruin, but gives abundant evidence in its towers and outworks of its former strength and magnificence. The finest of the towers was erected in 1242 by Hugues of Lusignan, and named after Mélusine, the mythical foundress of the family. The churches of St. Catherine and St. Augustin both date from the 13th century. An hotel de ville and a belfry, both of the 15th century, are of architectural interest, and the town possesses many curious old houses. There is a statue of General B. de Lari Cosièire (d. 1812), born in the town. Fougeres is the seat of a subprefecture, and has a tribunal of first instance, a chamber of commerce and a communal college. It is the chief industrial town of its department, being a centre for the manufacture of boots and shoes; tanning and leather-dressing and the manufacture of sail-cloth and other fabrics are also important industries. Trade is in dairy produce and in the granite of the neighbouring quarries. Fougeres frequently figures in Breton history from the 11th to the 15th century. It was taken by the English in 1166, and again in 1448; and the name of Surienna, the captor on the second occasion, is still borne by one of the towers of the castle. In 1488 it was taken by the troops of Charles VIII. under In Trémollié. In the middle ages Fougeres was a lordship of some importance, which in the 13th century passed into the possession of the family of Lusignan, and in 1507 was confiscated by the crown and afterwards changed hands many times. In 1793, during the wars of the Vendée, it was occupied by the insurgents.

**FOULÉE, ALFRED JÉRÉS ÉMILE** (1838— ). French philosopher, was born at La Pouize on the 18th of October 1838. He held several minor philosophical lectureships, and from 1864 was professor of philosophy at the lycées of Douai, Montpellier and Bordeaux successively. In 1869 and 1868 he was crowned by the Academy of Moral Science for his work on Plato and Socrates. In 1872 he was elected master of conferences at the École Normale, and was made doctor of philosophy in recognition of his two treatises, *Platonis Hippia Minor sive Socratica contra liberum arbitrium argumenta* et *La Liberté et le déterminisme*. The strain of the next three years' roundabout history his body undermined his health and his eyesight, and he was compelled to retire from his professorship. During these years he had published works on Plato and Socrates and a history of philosophy (1875); but after his retirement he further developed his philosophical position, a speculative eclecticism through which he endeavoured to reconcile metaphysical idealism with the naturalistic and mechanical standpoint of science. In *L'Évolutionnisme des idées-forces* (1890), *La Psychologie des idées-forces* (1893), and *La Morale des idées-forces* (1897), he elaborated his doctrine of idée-forces, or of mind as efficient cause through the tendency of ideas to realize themselves in appropriate movement. Ethical and sociological developments of this theory succeed its physical and psychological treatment, the consideration of the antinomy of freedom being especially important. Foulée's wife, who by a previous marriage was the mother of the poet and philosopher Jean Marie Guyau (1854—1888), is well known, under the pseudonym of "G. Bruno," as the author of educational books for children.

His other chief works are: *L'Idée moderne du droit en Allemagne, en Suisse et en France* (1879); *La Morale temporaire* (1880); La Proposérite sociale et la démocratie (1884); *Critique des systèmes de morale contemporains* (1883); *La Morale, l'art et la religion d'après Guyau* (1889); *L'Avenir de la métaphysique fondée sur l'expérienc*$ (1886); *L'Enseignement au point de vue national* (1891); *Descartes* (1893); L'Émancipation et l'instinct (2nd ed., 1895); *Le Mouvement positiviste et la conception sociologique du monde* (1896); *La Conception de la science moderne* (1896); *La Psychologie du peuple français* (2nd ed., 1898); *La France au point de vue moral* (1900); *L'Équilibre psychologique des peuples européens* (1903); Nietzsche et l'"immoralisme" (1903); *Le Morale* (1905).

**FOULD, ACHILLE** (1800-1867), French financier and politician, was born at Paris on the 17th of November 1800. The son of a rich Jewish banker, he was associated with and afterwards succeeded his father in the management of the business. As early as 1842 he entered political life, having been elected in that year as a deputy for the department of the Hautes Pyrénées. From that time to his death he actively busied himself with the affairs of his country. He readily acquiesced in the revolution of February 1848, and is said to have exercised a decided influence in financial matters on the provisional government then formed. He shortly afterwards published two pamphlets against the issue of paper money, entitled, *Pas d'Assignats* et *Observations sur la question financière*. During the presidency of Louis Napoleon he was four times minister of finance, and took a leading part in the economical reforms then made in France. His strong conservative tendencies led him to oppose the doctrine of free trade, and disposed him to hail the coup d'état and the new empire. On the 25th of January 1852, in consequence of the decree confiscating the property of the Orleans family,
he resigned the office of minister of finance, but was on the same day appointed senator, and soon after rejoined the government as minister of state and of the imperial household. In this capacity he directed the Paris exhibition of 1855. The events of November 1860 led once more to his resignation, but he was recalled to the ministry of finance in November of the following year, and retained office until the publication of the imperial letter of the 15th of January 1867, when Émile de la Bâtie was appointed chief adviser of the empire. During his last tenure of office he had reduced the floating debt, which the Mexican war had considerably increased, by the negotiation of a loan of 300 millions of francs (1865). Foulis, besides uncommon financial abilities, had a taste for the fine arts, which he developed and refined during his youth by visiting Italy and the eastern coasts of the Mediterranean. In 1857 he was made a member of the Academy of the Fine Arts. He died at Tarbes on the 5th of October 1867.

Foulis, Andrew (1712-1775) and Robert (1707-1766), Scottish printers and publishers, were the sons of a Glasgow maltman. Robert was apprenticed to a barber; but his ability attracted the attention of Dr Francis Hutcheson, who strongly recommended him to establish a printing press. After spending 1738 and 1739 in England and France in company with his brother Andrew, who had been intended for the church and had received a better education, he started business in 1741 in Glasgow, and in 1743 was appointed printer to the university. In this same year he brought out Demetrius Phalerus ex eloquio, in Greek and Latin, the first Greek book ever printed in Glasgow; and this was followed in 1744 by the famous 12mo edition of Horace which was long and erroneously believed to be immediate: though the successive sheets were exposed in the university and a reward offered for the discovery of any inaccuracy, six errors at least, according to T. F. Dibdin, escaped detection. Soon afterwards the brothers entered into partnership, and they continued for about thirty years to issue carefully corrected and beautifully printed editions of classical works in Latin, Greek, English, French and Italian. They printed more than five hundred separate publications, among them the small editions of Cicero, Tacitus, Cornelius Nepos, Virgil, Tibullus and Properlius, Lucretius and Juvenal; a beautiful edition of the Greek Testament, in small 4to; Homer (4 vols. fol., 1756-1758); Herodotus, Greek and Latin (9 vols. 12mo, 1761); Xenophon, Greek and Latin (12 vols. 12mo, 1762-1767); Gray's Poems; Pope's Works; Milton's Poems. The Homer, for which Flaxman's designs were executed, is perhaps the most famous production of the Foulis press. The brothers spared no pains, and Robert went to France to procure manuscripts of the classics, and to engage a skilled engraver and a copper-plate printer. Unfortunately he became their admiral for the encouragement of the fine arts; and though one of their chief patrons, the earl of Northumberland, warned them to "print for posterity and prosperity," they spent their money in collecting pictures, pieces of sculpture and models, in paying for the education and travelling of youthful artists, and in copying the masterpieces of foreign art. Their countrymen were not ripe for such an attempt, and the "Academy," not only proved a failure but involved the projectors in ruin. Andrew died on the 18th of September 1775, and his brother went to London, hoping to realise a large sum by the sale of his pictures. They were sold for much less than he anticipated, and Robert returned broken-hearted to Scotland, where he died at Edinburgh on the 2nd of June 1776. Robert was the author of a Catalogue of Paintings with Critical Remarks. The business was afterwards carried on under the same name by Robert's son Andrew.

FOULON, Joseph François (1752-1788), French administrator, was born at Saumur. During the Seven Years' War he was intendant-general of the armies, and intendant of the army and navy under Marshal de Belle-Isle. In 1771 he was appointed intendant of finances. In 1789, when Necker was dismissed, Foulon was appointed minister of the king's household, and was thought of by the reactionary party as a substitute. But he was unpopular on all sides. The farmers-general detested him on account of his severity, the Parisians on account of his wealth accumulated in utter indifference to the sufferings of the poor; he was reported, probably without foundation, to have said, "If the people cannot get bread, let them eat hay." After the taking of the Bastille on the 14th of July, he withdrew to his estate at Vitry and attempted to spread the news of his death; but he was recognized, taken to Paris, carried off with a bundle of hay tied to his back to the hôtel de ville, and, in spite of the intervention of Lafayette, was dragged out by the populace and hanged to a lamp-post on the 22nd of July 1789.

FOUNDATION (Lat. fundatio, from fundare, to found), the act of building, constructing or instituting on a permanent basis; especially the establishing of any institution by endowing or providing it with funds for its continual maintenance. The word is thus applied also to establishments such as a college, monastery or hospital; and the terms "foundation," or "founder," are used of members of such a college or society who enjoy, as fellows, scholars, &c., the benefits of the endowment. Formerly "foundation" also meant the charter or incorporation of any such institution or society, and it is still applied to the funds used for the endowment of such institutions.

The terms "old foundation" and "new foundation" used in connection with the organizing of English cathedral chapters have no reference to the age of the cathedrals. At the time of the Reformation under Henry VIII. the old college chapters were left unchanged, and are referred to as the "old foundations," but the monastic chapters were all suppressed, consequently new chapters had to be formed for their cathedrals and these constitute the "new foundations."

"Foundation" also means the base (natural or artificial) on which any erection is built up; generally made below the level of the ground (see Foundations below). A foundation-stone is one of the stones at the base of a building, generally a corner-stone, frequently laid with a public ceremony to celebrate the commencement of the building. The term is also applied to the ground-work of any structure, such as, in dress-making, the underskirt over which the real skirt is hung, any material used for stiffening purposes, as "foundation muslin or net."

In knitting or crochet the first stitches on to which all the rest are worked are called the "foundation chain." In gem-cutting the "foundation-square" is the first of eight squares round the edges of a brilliant made in bevel planes and from which the angles are all removed to form three-corner facets.

FOUNDATIONS, in building. The object of foundations is to distribute the weight of a structure equally over the ground. In the construction of a building the weights are concentrated at given points on piers, columns, &c., and these foundations require to be spread so as to reduce the weight to an average. In the preparation of a foundation care must be taken to prevent the lateral escape of the soil or the movement of a bed upon sloping ground, and it is also necessary to provide against any damage by the action of the atmosphere. The soils meet with in ordinary practice, such as rock, gravel, clay, sand, or clay, vary as to their capacities of bearing weight. There is no provision in any English building acts as to the load that may be placed on any of these soils, but under the New York Building Code it is provided that, where no test of the sustaining power of the soil is made, different soils, excluding mud, at the bottom of the footings shall be deemed to safely sustain the following loads to the superficial foot:

A comparison of the pressure exerted on an ordinary foundation by the walls of the several thicknesses and heights provided for by the London Building Act of 1894, and a comparison of a few of the principal authorities, will be found useful in helping us to arrive at a decision as to what can safely be allowed. Take as an example a wall of the warehouse class, 70 ft. high, whose section at the base for a height of 27 ft. is 2½ bricks thick (or 22½ in.), and for the same distance in height again is 2 bricks thick (or 18 in.), the remainder to the top being 1½ bricks thick (or 14 in.). The weight of brickwork per foot run of such a wall is 4-05 tons on any area of 3-75 ft. super. of brickwork. According to the act the concrete is to project 4 in. on each side; we have then an additional area of 60 ft. super. to add, thus making the total foundation area of each foot run of wall 4-41 ft. super. to take a weight of 4-05 tons or nearly a ton per foot super (viz. 9 tons).

Another factor must, however, be taken into consideration, viz. the weight distributed from the loaded floor and from the roof. In this case there would be at least six floors, and the entire weight could hardly be taken at less than 6 tons, which would give a total weight of 10-05 tons on an area of 4-41 ft. super, or a load of 2-28 tons per foot super. This is on the assumption that no extra weight has been thrown on the foundations by openings or piers, or by girders, &c., in which case, in addition to the work being executed in cement, the foundations should be increased in area. Piers always involve a greater increase of weight on the foundations, and in very many instances this increase of weight is at least being provided for by increasing the area of the foundations and so reducing the weight per foot super, is only partly met by the improper method of merely increasing the depth of the concrete, while keeping the same projection of concrete round the footings as for the walls. As an example take an iron column to carry a safe load of 80 tons, standing on a York stone template, and in turn supported by a brick pier 22½ in. square. In this case we should have, after allowing for the projection of concrete on either side, an area of 4 ft. 5 in. square, or 19-6 ft. super., and this would give a pressure of 4-1 tons per foot on the foundations, or almost twice as much as in the previous example of a warehouse wall. Here, instead of increasing the depth of the concrete, it would be necessary to increase its width; if it were made 6 ft. square, we should have an area of 36 ft. super. to take the 80 tons, and thus the pressure would only be 2-2 tons per foot, and the cost of the foundation would be much the same.

If we compare a section of wall of the dwelling-house class, as prescribed by the London Building Act, we find that, taking a wall 30 ft. high and having a thickness at base of 22½ in. as for the warehouse wall to which we have referred, we have a wall weighing 3-75 tons per foot super. on an area of 4-41 feet super., or 83 tons per foot without weight of floors and roof as against the 9-ton in the warehouse example. To this must be added the weight of, say, 5 floors and roof at a total of 3 tons per foot run of wall, and we then have an aggregate of 6-75 tons per foot run and 1-50 tons per foot super. as against 2-28 tons in the warehouse class. If we turn from the act to text-books we find that Colonel Seddon in the Aide Memoir gives the load which ordinary foundations will bear as a safe load per foot super. as follows:

<table>
<thead>
<tr>

</tbody>
</table>

Most of the work in London may be classed under one of the latter heads, and according to this table we have, when we erect walls in accordance with the building act, to overload our foundations.

As to the possibility of spreading weights, we have as an example the chimney at Adkin's Soap Works in Birmingham, 312 ft. high, so arranged that its pressure on the foundations is only 1¼ tons per foot super.; also the great St Rolof chimney at Glasgow, which has a pressure of 1¾ tons; the weight of the Eiffel Tower (7500 tons) is so spread over 4 bases, each 130 ft. square, that the pressure is only 177 tons, or 2½ cwt., per foot super. The Tower Bridge has a load of 16 tons per foot on the foundation, or considerably under the weight of a chimney, and yet it is so spread to an actual pressure on the clay foundation of 4 tons. The piers under the Holborn Viaduct have a load of 2½ tons only, those of the Imperial Institute 2½ tons, and those of the destructor cells and chimney shaft at Great Yarmouth 4 tons 6½ cwt. per foot super. From these various examples it would appear that on sound clay or gravel foundation a load of from 2 to 4 tons may be employed with safety.

One of the first and most important requirements in preparing drawings for a large building is to ascertain the nature of the subsoil and strata at different levels over the proposed site, so as to be able to arrange the footings accordingly at the various depths and to decide as to the various forms and methods to be employed. For this purpose trial holes or borings are sunk until a suitable bed or bottom is found, upon which the foundations may be laid. In the case of most buildings the subsoil is found, as often happens near the water side, special foundations must be employed, such as dock, gridiron, cantilever and pile foundations, &c., all of which will be described hereafter. As examples of deep foundations being adopted we may say that the subsoil at London Bridge has been noticed the great depths dug before getting through the made ground: At the Bank of England there were 22 ft. of made ground resting on 4 ft. of gravel. Some of the made ground was of ancient rivers' deposits, the remainder of the gravel deposits of the Thames, and the latter have been found to be soft and dirty; (2) 2 ft. peat clay; (3) 4 ft. grey clay; (4) 3½ ft. peaty bog; (5) 6 ft. running sand; and (7) 4 ft. clean ballast, resting at a depth of 3 ft. below the ground line upon blue clay. A boring at Highbury New Park gave: (1) 2 ft. made ground, (2) 18 ft. loam, (3) 9 ft. sand, (4) 4 ft. peat, and (5) 8 ft. gravel and sand. These examples show that while trial holes should always be made before designing a foundation, to ascertain the nature of the subsoil, care should be taken not to go too deep, otherwise the walls of the Offices of the new admiralty buildings are placed in a dock, built upon the London clay at a depth of 30 ft. in solid concrete 6 ft. thick. At the Hotel Victoria, in Northumberland Avenue (now Euston Road), various, varied, and novel, 38½ ft. made ground clay and gravel mixed, (2) 4 ft. gravel and sand, (3) 6 ft. rising sand; (4) 2 ft. fine ballast, and at a depth of 50 ft. blue clay. At the south end the clay was 43 ft. down and at the north 37 ft. The front wall was constructed on a concrete bed 3 ft. wide. The site was surrounded by a similar wall of concrete about 6 ft. wide, forming a species of boxes, and the whole was covered with a depth of 6 ft. of concrete upon which the walls were raised. The foundation for the Parliament Station for the Houses of Parliament, where the wall which was encountered, was constructed with short piles, 7 or 8 ft. long and 6 in. diam., pointed and placed as close together as possible over the whole foundation, the tops were then sawn off level, and a concrete raft, 7 or 8 ft. thick, was built over the whole area. At the Institution of Civil Engineers, Great George Street, Westminster, the foundations to the two party walls upon each side of the building were carried down about 22 ft. below the pavement level, that on the west side being 22 ft. deep and that on the east side 24 ft.

Under the London Building Act and the model by-laws prohibit the erection of buildings on sites that have been used as "shotts" for faecal matter or vegetable refuse, and in such cases the objectionable material must be removed prior to the commencement of building operations, and the soil from which it was taken filled up with dry brick or other rubbish well rammed. Foundations are usually executed by excavators or navvies, and the tools and implements used are boring rods, level pegs, lines, spirit level, plumb, plumb, various shovels, wheel-barrow, rammer or punner, &c. In digging the ordinary trenches and
foundations, should the ground be loose, plastering and strutting have to be employed. This consists of rough boarding put along the sides of the trenches and wedged tight with wailing pieces and struts; this work is done by navvies. Figs. 1 and 2 show the general forms of plastering and strutting for the different soils.

In very large works of excavation in soft soil a steam digger is used for the bulk of the work. It consists of a large steel bucket with a cutting edge; this is lowered by means of a crane to the depth of excavation, and, on being withdrawn, cuts off a portion of soil which is hauled away in a cart. The work of trimming the excavation to a regular shape must always be done by manual labour.

Concrete for filling in the foundations is usually mixed by navvies; for large works it is sometimes mixed by machinery.

In order that the work of excavating and consolidating the foundations may proceed in a water-logged site, sumps have to be employed, and where the inrush of water is great it is usual to sink a sump hole lower than the depth required for the foundations, and to use a steam pump kept going day and night.

The building act requires as follows in this respect:

"The projection of the bottom of the footings of every wall on each side of the wall shall be at least equal to half the thickness of the wall at its base, unless an adjoining wall interferes, in which case the projection must be omitted where that wall adjoins, and the diminution of the footings of every wall shall be formed in regular offsets and the height from the bottom of each footing to the base of the wall shall be at least equal to two-thirds of the thickness of the wall below the base." (See Brickwork.)

The base of a wall is the thickness above the footing; the footing is the brickwork built directly on the top of the concrete and diminishing in width in every course. Thus: "The projection of the bottom footing to be equal to one-half the thickness of wall on both sides" means that a 13-in.-wall footing would require to have three courses of footings, the bottom one being 27 in. wide. "The height from the bottom of each footing to the base of the wall shall be at least equal to two-thirds of the thickness of the wall below the base." (See Foundation.)

The New York Building Code enters more fully into the requirements for the foundations of walls as regards depth than that in use in London. Section 25, Part 5, requires that every building, except buildings erected upon solid rock, or upon wharves and piers when solid earth or rock is not found. Piles intended to support wall, pier or post, shall be spaced not more than 36 in. nor less than 20 in. on centres; they must be driven to a solid bearing if practicable, and their number must be sufficient to support the superstructure proposed. No pile shall be used of less diameter than 5 in. at the small end and 10 in. at the butt for short piles, or piles 20 ft. or less in length. No pile shall be weighted with a load exceeding 40,000 lb. When a pile is not driven to refusal, its safe sustaining power shall be determined by the following formula: twice the weight of the hammer in tons multiplied by the height of the fall in feet divided by the least penetration of pile under the last blow given to it. This formula is also used for driving piles, &c., and the commissioner of buildings must be notified when the piles are to be driven.

The New York Code, Section 26, further goes on to say that foundations for walls extend to a depth of 4 ft. below the surface of the ground, unless piles are employed. Fig. 1 and 2 show the general forms of footing. Foundation walls built below the curb level or nearest tier of beams to the curb, to serve as supports for the walls, piers, columns, girders, posts or compound beams. These may be brick, stone, Portland cement concrete, iron or steel. If built of rubble stone or Portland cement concrete, they shall be at least 8 in. thicker than the wall above them to a depth of 12 ft. below the curb level, and for every additional foot below the curb, 2 in. more in thickness. If built of brick, they shall be at least 4 in. thicker than the wall next above them to a depth of 12 ft. below the curb level, and for every additional 10 ft. or part thereof deeper, they shall be increased 2 in. in thickness; such footing shall be of stone or concrete, or both, or of concrete and stepped up brickwork of sufficient thickness and area to bear safely the weight to be imposed thereon. If the footing or base course be of concrete, the concrete shall not be less than 12 in. thick; if of stone, the stones shall not be less than 2 x 3 ft.; and at least 8 in. in thickness for walls, and not less than 10 in. in thickness if under piers, columns or posts. The footings for light weights shall be at least 12 in. thinner than the bottom width of walls, and at least 12 in. wider on all sides than the bottom width of said piers, columns or posts. 16 base piles, as under normal strain, shall serve to resist strain on a footing projecting 12 in., the thickness of such footing to be increased so as to carry the load with safety. For small structures and for small piers sustaining light loads the commissioner may, in his discretion, reduce the number of piles or allow a reduction in the thickness and projection specified for footing or base courses. All base stones shall be bedded and laid creosote, edge to edge. If stepped-up footing of brick is used in place of stone, the concrete the offsets if laid in single courses shall not exceed 13 in., or, if laid in double courses, then each shall not exceed 3 in. offsetting the first course of brickwork back one-half the thickness of the concrete base, so as properly to distribute the load to be imposed thereon. It will be seen by the foregoing that the American acts are far more extensive than in London. The London Building Act mentions that the footings of a wall shall rest on solid earth or rock, or upon piles or walls, the weight of which is at least 12 in. wide, and not less than 9 in. in thickness, with a projection at least 4 in. on each side of the lowest course of footings.

Various Types of Foundations.—The most natural foundations for walls are those constructed where the walls are built directly upon the ground; this is only possible where the ground is very hard or consists of rock, and in either of these cases the ground is simply levelled and the building commenced.

The least and most universally recognized method, which might safely be said to be adopted in 3/4 of all modern building, is the system of placing a bed of concrete under the walls, digging trenches where the walls are to come until a solid bottom is reached, and placing the London concrete bed in thus formed trench. The London Building Act requires that the concrete bed shall be at least 4 in. wider than the bottom course of footings on each side of the wall, but it is generally made 6 in. wider on each side and in general circumstances the depth of the concrete is increased from above to 3 ft. where a site is in close proximity to a river or old water-course, &c., where deep basements are excavated, or where the ground lies low, naturally water is met with, and where water be of concrete, safety. If the floors or basements are required to have three courses of footings. These are placed in such positions as to take the weights of the building, and run in and to a depth of 40 ft. more or less as the case may be, and require according to the nature of the ground; and on the tops of these stilts concrete arches or lintels are formed (Fig. 3). As an example of this principle mention may be made of some premises at Stone Street, New York, where a church at South Bermondsey, London, in which concrete piers were sunk at 12 ft. centres apart and 43 ft. square, in pot holes dug out of made ground; then concrete arches were formed over the intervening untrustworthy ground with a minimum thickness of 12 in. or the piers were connected by concrete lintels 3 ft. thick in which the joints were embedded. At Sion College, Victoria Embracement, London, these stilts were used to support a church, concrete stilts or piers 8 ft. square, and going down to the London clay; from the tops of these stilts brick arches were turned, spanning and forming piers, and piers and the intermediate arches were built up to this level.

Pile foundations, used in the case of soft ground, for small works, consist either of stout scaffolding poles or of timbers varying from 6 in. square and 6 ft. long to 10 in. square and 3 ft. long. The ends of these timbers have an iron shoe with a point, so as to be easily driven into the ground, and the tops of the timbers have an iron band round, so that when the timbers are being driven in

---

**Fig. 1.**

**Fig. 2.**

[Image of a foundation structure with relevant details for reading.]
the band prevents them from splitting (fig. 3). The methods of driving these piles are various. The usual plan is to erect a temporary structure, upon one side of which is a guide path faced with sheet-iron so as to give a smooth face. Up and down this guide path a heavy iron weight, called a monkey, is worked; the monkey is hoisted to the top of the guide path by means of a crane worked by hand or steam, and when released descends with a good force, and so drives the piles into the ground. The monkey usually weighs from 2 cwt. to 10 cwt. and is allowed a drop of 15 to 40 ft.

Piles are driven all round under the walls at varying intervals or under piers where the weights of a building are to be concentrated. In the erection of the Chicago public library four Norway pine piles, each with an average diameter of 13 in., were driven to a depth of 52 ft. and loaded with a dead load of 50 to 70 tons per pile for a period of two weeks, and no settlement taking place 30 tons per pile was adopted as a safe load. The following are some examples of loads used in practice: passenger station, Harrison Street, Chicago, piles 50 ft. in length, each carrying 25 tons; elevator, Buffalo, N.Y., piles 20 ft. in length, weight 25 tons; Trinity church, Boston, 2 tons; Schiller building, Chicago, 55 tons per pile, but in this case the building settled considerably. All timber grillage and the tops of all piles should be kept below the lowest water level, and be capped with concrete or stone. In Boston it is obligatory to cap with blocks of granite.

Another form of foundation takes the shape of Portland cement concrete blocks, and is used chiefly for bridges and in marshy land, &c. In some cases cylinders of brickwork are built, and the centres are filled with blocks of concrete and grouted in. The Yarmouth destructor cells and chimney shaft were built in this way; the cylinders were constructed of 9 in. brickwork built in Portland cement, the lower 4 ft. being encased in a wooden drum with cutting edge sunk into the gravel and sand at least 2 ft. The cylinders were sunk by the aid of a grab, the bottom being levelled and the concrete blocks laid by a diver. Use is also made of piles consisting of Portland cement concrete having steel rods embedded in it, and provided with iron shoes and head for driving (fig. 6).

Cast iron screw piles (fig. 7) used in very loose sandy soils, consist of large hollow cast iron columns with flat screw blades cast on the lower ends. The projection of this screw from the pile may vary from 9 in. to 18 in. with a pitch of from one-quarter to one-half of the projection, the blade making a little over one turn round the shaft. For most requirements a diameter of screw from 33 to 43 in. will be found sufficient, a sandy foundation requiring the largest. The lower end of the tube is generally left open, the edge being bevelled and occasionally provided with teeth to assist in cutting into and penetrating the soil.

Another system of piling known as sheet piling (fig. 8), consists in driving piles into the ground at intervals, and between these, also driven into the ground, are timbers measuring 3 in. by 9 in., which form a wall to keep the soft earth up under the building. In this way the earth is prevented from spreading out and so causing the building to settle unevenly. Another kind of foundation, known as plank foundation (fig. 9), consists of elm planks, about 9 in. by 3 in. laid across the trench and spiked together; on the top of these are laid similar planks but at right angles to the last, and upon the platform thus formed the wall is built. This method is used in soft ground.

Caissons are usually employed by engineers for the construction of the foundations of bridge piers, but instances of their use in foundations for buildings are to be found in the American Surety and the Manhattan Life Insurance buildings, New York City. The latter building is 242 ft. high to the parapet and the dome and tower rise 108 ft. higher. The building is carried on 16 solid masonry piers, taken down 54 ft. below the street level to solid rock, and these piers support the 34 cast iron columns upon which the building is erected. The piers to each building were constructed by the pneumatic caisson process (see Caisson). A good plan for foundations when the ground is loose and sandy is to build upon wells of brickwork, a method which has been successfully practised in Madras. The wells are made circular, about 3 ft. in diameter and one brick thick. The first course is laid and cemented together on the surface of the ground when it is dry, and the earth is excavated inside and round about it to allow it to sink. Then another is laid over it and again sunk. The well is thus built downwards. The brickwork is sunk bodily to a depth of 10 ft. or more, according
to building to be erected upon it, and the interior is filled up with rubble work. All the public buildings at Madras were erected upon foundations of this kind. Well foundations were employed under the city hall, Kansas City, and the Stock Exchange, Chicago.

Coffer dams are wooden structures used to keep back the water whilst putting in foundations on the waterside, and are constructed with two rows of timbers, 12 in. square as piles spaced about 6 ft. apart, and filled in between with a double row of 2 in. or 3 in. boards, the space between the rows being packed with clay-puddle (fig. 10). The general rule for the thickness of a coffer dam is to make it equal to the depth of water. An interesting example of a coffer dam is at the Keyham dock extension, where piles varied in length from 65 ft. to 85 ft. They were driven in a double row 5 ft. apart, and over 13,000 were used.

Dock foundations are constructed after the fashion of a large concrete tank, and are adapted to large sites where a difficulty arises as to the ingress of water. They are considered the best method of constructing a building on soft ground and of keeping a building dry (fig. 11). This type of foundation was used at the new colonial office, Whitehall, London, and the new admiralty buildings at St. James's Park, London. A few buildings treated after the style of a dock, but in some instances without the enclosing walls, are the following:

At the admiralty buildings already mentioned a concrete retaining wall completely surrounds the exterior below the ground, and is joined up to the underpinning work; the whole site being covered with concrete 6 ft. thick, a huge tank is formed of an average inside clear depth of 20 ft. in which the basements are built. The new Old Bailey buildings in Newgate Street, London, are constructed on a concrete table 5 ft. thick, as also are the Army and Navy Auxiliary Stores, Victoria Street. At Kennet's Wharf, near Southwark Bridge, a concrete table, 8 ft. thick, was spread all over the site, with an extra thickness under the walls. Foundations formed similarly to dock foundations, but in addition having steel joists and rods inserted in the thickness of the concrete table, to tie the whole together, are known as gridiron foundations.

In the Hennebique concrete system, all beams, &c., are formed with small rods and then surrounded with concrete; it is designed for floors and for spreading the weight of a building over an extended foundation on soft ground.

Where a heavy wall is to be built against an old one and there is not sufficient room for the foundations, the plan is adopted of building pier foundations at some distance from the proposed new wall. On the top of these piers rest cantilevers over steel pin rockers upon cast-iron bedplates; the cantilevers are secured in position against the column, while the other ends go through the full thickness of the new wall. Upon these last ends is placed a steel girder upon which the wall is built. This construction (fig. 12) has been adopted in America, and in the Ritz Hotel, Piccadilly, London.

Another form of cantilever foundations was employed in the case of some premises at Carr's Lane, Birmingham, partly built over the Great Western railway tunnel (fig. 13). In this instance large piers were built below the ground at the side of the tunnel. From the tops of these piers large steel cantilevers were erected projecting over the crown of the tunnel, and on these steel girders were fixed and the building constructed upon them.

In modern Tunis, a section of which city is built on marshy ground, the subsoil is an oozy sediment, largely deposited by the sewage water from the ancient or Arab quarter of the city, which is situated on an adjacent hill. This semi-liquid mud has a depth of about 15 ft. To prepare the soil for supporting an ordinary house, pits from 8 ft. to 10 ft. square are excavated to a depth of about 10 ft., to the level of the ground water. A mixture is made of the excavated oozy mud and powdered fat lime, procured from clinkers and unburnt stone from the lime-kilns, which soon crumbles to fine dust when exposed to the air. The mixture is thrown into pits in layers about 12 in. thick and rammed down for a very long time by specially trained labourers. A gang of 15 or 20 men will work at least 10 or 12 days ramming for the foundations of a moderate-sized house. An extremely hard bed is thus obtained, reaching to within 18 in. of the surface of the ground, and on this artificial bed the foundations of the building are laid. Although this method of construction is crude, it is stated that the practical results are superior to those obtained by using piles, concrete or other recognized methods, and in all cases the cost is much less, for labour is cheap.

A novel and interesting foundation was designed for a signal station at Cape Henlopen, Delaware. This is built on the highest sandhill at Cape Henlopen, so that the observer may have an unobstructed view; it rises about 80 ft. above the level of the sea and is exposed to all winds and weather, while it is absolutely required that it shall stand firmly planted in such a way that even a hurricane shall not shake it or make it tremble, since that would affect the right angle of the telescope in the observatory. The usual mode of securing such a building is by means of a foundation of screw piles or of heavy timber and from the sand; this method, however, has the disadvantage that if the wind shifts the sand away from around the foundation, it becomes undermined and its effect is destroyed. To avoid such an accident, recourse was had to the following design, which was considered at the same time to be cheaper and safer than any other anchorage. The building is entirely of wood; it has a cellar, above which are two rooms one above the other, and the whole is
FOUNDING (from Lat. *fundere*, to pour), the process of casting in metal, of making a reproduction of a given object by running molten metal into a mould taken in sand, loam or plaster from that object. To enable the founder to prepare a mould for the casting, he must receive a pattern similar to the casting required. Some few exceptions occur, to be noted presently, but the above statement is true of perhaps 95% of all castings produced. The construction of such patterns gives employment to a large number of highly skilled men, who can only acquire the necessary knowledge through an apprenticeship lasting from five to seven years. A knowledge of two trades at least is involved in the work of pattern construction—that of the craft itself and that of the moulder and founder. Patterns have to be constructed strongly. They are generally of wood, and they thus require skill in the use of woodworking tools and the making of timber joints, together with a knowledge of the behaviour of timber, &c. Some few patterns are made in iron, brass or white metal alloys. They have to be embedded in a matrix of sand by the founder, and being enclosed, they have to be withdrawn without inflicting any damage in the way of fracture in the sand. Since cast work involves shapes that are often very intricate, including projections and hollow spaces of all forms, it is obvious that the withdrawal of the patterns without entailing tearing up and fracture of the sand must involve many difficult problems that have to be as fully understood by the pattern-maker as by the moulder. It is from this point of view that the work of the pattern-maker should be approached in the first place. No closed mould can possibly be made without one or more joints, for if a pattern is wholly enclosed in a matrix of sand it cannot be withdrawn except by making a parting in the sand, and it is not difficult to conceive that the parting in the pattern might advantageously be made to coincide, either exactly or approximately, with that of the mould. Nor must obstacles exist to the free withdrawal of patterns. They must therefore not be wider or larger in the lower than in the upper parts; actually they are made a trifle smaller or “tapered.” Nor may they have any lateral extensions into the lower sand, unless these can be made to withdraw separately from the main portion of the pattern. Finally, there are many internal spaces which cannot be formed by a pattern directly in the sand, but provision for which must be made by some means extraneous to the pattern, as by cores.

A single example must illustrate the main principles which have just been stated. The object selected is a bracket which involves questions of joints, of cores, of pattern construction and of moulding. The casting, the pattern, and its mould are illustrated. Fig. 1 illustrates in plan the casting of a double bracket, the end elevation of which is seen in fig. 2; the pattern of which presents obvious difficulties in the way of withdrawal from a mould, supposing it were made just like its casting. But if it be made as in fig. 3, with the open spaces A, B, in fig. 2, occupied with core prints, and the pieces A, A in fig. 3 left loosely skewered on, everything will “deliver” freely. Moreover the pattern might be made solidly as shown in fig. 3, or else jointed and dowelled in the plane a-a, as in fig. 4, or along the upper faces of the prints b-b, fig. 3. The

corrugated iron roof conical in shape. The cellar is floored with 3 in. wood, and boarded all round on the inside of the posts. A pit was first dug in the sand about 6 ft. deep and fully 20 ft. wide on the bottom. The cellar sill was laid on this bottom, and the structure built upon it; thus the whole depth of cellar is sunk below the top of the hill or the level of the sand. The cellar was then filled up with sand and packed solid all round, consequently the building is anchored in its place by the load in the cellar, about 100 tons in weight.

The subject of foundations, being naturally of the first importance, is one that calls for most careful study. It is not of so much importance that the ground be hard or even rocky as that it be compact and of similar consistency throughout. It is not always that a site answers to this description, and the problem of what will be the best form of foundation to use in placing a building, more especially if that building be of large dimensions and consequently great weight, on a site of soft yielding soil, is one that is often most difficult of solution. The foregoing article indicates in a brief manner some of the obstacles the architect or engineer is required to surmount before his work can even be started on its way to completion.

(J. Br.)
timber shadings in figs. 3 and 4 illustrate points in the most suitable arrangement of material. The prints are "boxed up." Fig. 4 shows a certain stage of the moulding, in which one half of the pattern has been "rammed" in sand, and turned over in the "bottom box," and the upper half is ready to be rammed in the "top box," with "runner pin" or "pit stick" A, set in place. The lower loose piece has had its skewer removed during the ramming. Fig. 5 illustrates the mould completed and ready for pouring. The boxes have been parted, the pattern has been withdrawn, cores inserted in the impressions left by the prints, vents taken from the central body of sand, the pouring basin made and the boxes coterter together.

Every single detail now briefly noted in connexion with this bracket is applied and modified in an almost infinite number of ways to suit the ever varying character of foundry work. Yet this process does not touch some of the great subdivisions of moulding and casting. There is a large volume of large and heavy work for which complete patterns and core boxes are never made, because of the great expense that would be involved in the pattern construction. There are also some cases in which the methods adopted would not permit of the use of patterns, as in that group of work in which the sand or loam is "swept" to the form required for the moulds and cores by means of striking boards, loam boards, core boards or strickles. In these classes of moulding the loose green sands and core sands are not much used; instead, loam—a wet and plastic sand mixture—is employed, supported against bricks (loam moulds) or against core bars and plates, and hay ropes (loam cores). All heavy marine engine cylinders are thus made by sweeping, and all massive cores for engine cylinders and large pipes, besides much large circular and cylindrical work, as foundation cylinders, soap pans, lead pans, mortar pans, large propeller blades, &c. In these cases the edge of the striking board is a counterpart of the profile of the work swept up. Joints also have to be made in such moulds, not of course in order to provide for the removal of a pattern, but for the exposure turned over into place, and the metal is poured into the space b, b, between the two moulds. There is also a large group of swept-up work which is not symmetrical about a centre of rotation. Then the movements of the sweeping boards are controlled by the edges of "core plates," or of "core irons" (fig. 7). Bend pipes, and the

![Fig. 7](image7.png)

volute casings of centrifugal pumps and pipes, afford examples of this kind. In fig. 7, A is the core iron, held down by weights, and B the "strickle," sweeping up the half bend C, two such halves pasted together completing the core.

Core-making is a special department of foundry work, often involving as much detail as the construction and moulding of patterns. Two perfectly plain boxes are shown in figs. 8 and 9, in both of which provision exists for removing the box parts from the core after the latter has been rammed. Core boxes are jointed and tapered, and often have loose pieces within them, and also prints, into the impressions of which other cores are inserted.

**Founding**

**Core-making.**—There is a development of modern methods of founding which is effecting radical changes in some departments of foundry practice, namely, moulding by machines. The advantages of this method are manifold, and its limitations
are being lessened continually. There are two broad departments between which machine-moulding is divided. One, of less importance, is that of toothed wheels; the other is that of general work, except of a very massive character.

Gear-wheel moulding machines are essentially a special adaptation of the mechanism of the dividing engine, by means of which, instead of using a complete pattern of a toothed wheel, two or three pattern teeth are used, and the machine takes charge of the correct pitching or division of the teeth moulded therefrom, leaving to the moulder the

work only of turning the handle of the division plate, and ramming the sand around the pattern teeth. The result is accurate pitching, and the use of two or three teeth instead of a full pattern, together with any core boxes and striking boards that are necessary for the arms.

The other department of machine moulding includes nearly every conceivable class of work of small and medium dimensions. There are some dozens of distinct types of machines in use, for no one type is suitable for all classes of moulds, while some are designed specially for one or two kinds only.

The fundamental principles of operation are briefly these: The pattern parts constitute, by their method of attachment to a plate or table A (fig. 10), an integral portion of the machine, so that they must partake of certain movements which are imparted to it. Often patterns mounted, as in fig. 10, are moulded by hand, without any aid from a machine, by methods of "plate-moulding." The division of the pattern from the sand is invariably accomplished by a perpendicular movement of a portion of the machine (fig. 11), withdrawing either the pattern from the mould or the mould from the pattern. The important point is that the perpendicular movement is under the coercion of the vertical guides provided in the hand machines, or the hydraulic ram in fig. 11, is free from the unsteadiness which is incidental to withdrawal by the hands of the moulder; and if the machine performed nothing more than this it would justify its existence. Little or no taper is required in the pattern, and the moulds are more nearly uniform in dimensions than hand-made moulds. But there are other advantages. In machine-moulding the joint

faces for parting moulds are produced by the faces of the plates on which the pattern is mounted (figs. 10 and 11), instead of by the hands and trowel of the moulder. When the joint face is of irregular outline, as it often is, this item alone saves a good deal of time, which again is multiplied by the number of moulds repeated, often amounting to thousands. Further, provision is generally made on machine plates for the ingates and runners (fig. 10) through which the metal enters the mould, the preparation of which in hand work occupies a considerable amount of time. Another great advantage applies especially to the case of deep moulds. These give much trouble in hand-moulding in consequence of the liability of the sand to become torn up during the withdrawal of the pattern. But in machine-moulding such patterns are encircled by a plate, termed a "stripping plate," which is pierced to allow the patterns to pass through, and which, being maintained firmly on the sand during the lifting of the pattern, prevents it from becoming torn up. This is not merely a matter of convenience, but is a necessity in numerous instances. The most familiar example is that of the teeth of gear wheels, in which a very slight amount of taper interferes with accurate engagement, and this is representative of many other portions of mechanism. These stripping

plates are of metal, but in order to save the cost of filing them in iron or steel, many are simply made by casting a white metal alloy round the actual pattern itself in the first place, the white metal being enclosed and retained in a plain iron frame which forms the body of the plate. Lastly, many machines, but not the majority, include provision for mechanically ramming the sand around the pattern by power instead of by hand. This is really the least valuable feature of a moulding machine, because it is not applicable to any but rather shallow moulds. It is commonly used for these, but the consistence and homogeneity of a mass of sand round a pattern having deep perpendicular sides can only be ensured by careful hand ramming.

The highest economies of machine-moulding are obtained when (1) several small patterns are mounted and moulded at once on a single plate (fig. 10); (2) when top and bottom parts of a mould are made planished as mentioned in its moulding on different sides, of the pattern; (3) when the machine and pattern details are simplified so much that the labour of trained moulders is displaced by that of unskilled attendants who are taught in a month or two the few simple operations required. That is the direction in which repetitive casting is now rapidly tending.

In fig. 11 A is the plate, which in its essentials corresponds with the plate A in fig. 10, but which in the machine is made to swivel so as to bring each half of the pattern B, B in turn uppermost for ramming in the box parts C, C. The ramming is done by hand, the final squeeze being imparted against the presser D by the action of the hydraulic ram E pushing the plate, mould and box up against D. The plate being then lowered, and turned over, the further descent of the ram withdraws the bottom box from the pattern, which is the stage seen in the illustration. Then the half mould is run away on the carriage it, provided with wheels to run on rails.

Though casting in iron, steel, the bronzes, aluminium, &c., is
FOUNDLING HOSPITALS

originally institutions for the reception of "foundlings," i.e., children who have been abandoned or exposed, and left for the public to find and save. The early history of such institutions is connected with the practice of foundling, in which the practice of infanticide, and in western Europe where social disorder was rife and famine of frequent occurrence, exposure and extensive sales were the necessary means of maintaining the institution. Against these evils, which were noticed by several councils, the church provided a rough system of relief, children being deposited (jactati) in marble shells at the church doors, and tended first by the matricullari or male nurses, and then by the nutricier or foster-parents. But it was in the 7th and 8th centuries that definite institutions for foundlings were established in such towns as Trier, Milan and Montpellier. In the 15th century, Garcia, archbishop of Valencia, was a conspicuous figure in this charitable work, but his fame is entirely eclipsed by that of St. Vincent de Paul, who, in the reign of Louis XIV, with the help of the countess of Joigny, Mme Le Gras and other religious ladies, rescued the foundlings of Paris from the horrors of a primitive institution named La Couche (rue St Landry), and ultimately obtained from Louis XIV, the use of the Bicetre for their accommodation. Letters patent were granted to the Paris hospital in 1670. The HÔtel-Dieu of Lyons was the next in importance. No provision, however, was made outside the great towns; the houses in the cities were overcrowded and administered by laxity; and in 1784 Necker prophesied that the state would yet be enriched by the foundlings. The laws of 1763, which received the sanction of the court, were the necessary means of stemming these evils. Against these, the law of 1811 directed that there should be an asylum and a wheel for receiving foundlings in every arrondissement. The last "wheel," that of Antwerp, was closed in 1860. (See "Institutions de bienfaisance et de protection en Belgique, 1850 à 1860," by M. P. Leloir.)

Italy is very rich in foundling hospitals, pure and simple, orphans and other destitute children being separately provided for. (See "Della carità preventiva in Italia," by Signor Fano.) In Venice, the Soccorso dei Bambini has been a benefit of the hospital, being the result of the instruction of February 1823, the decree of the 4th of March 1825, the law of 1831, and the creation of the Società Nazionale dei Bambini, 1831. In the conduct of the hospital, the number of foundlings is in the hands of the executive committee, formed by the confratelli of the hospital. (See "Institutions de Rome," by Cardinal Morlincini.) In Venice the Casa degli Esposti or foundling hospital, founded in 1436, and receiving 450 children annually, is under provincial administration. The splendid legacy of the last ducat, Ludovico Manin, is applied to the

the 5th of May 1869, the law of the 24th of July 1889 and the law of the 27th of June 1904. These laws carry out the general principles of the law of 7 Frimaire An V., which completely decentralized the system of national poor relief established by the Revolution. The principal objects are to (1) ensure the proper establishment of foundlings, (2) the maintenance of the last-named foundlings in a proper, (3) children abandoned by their parents, (4) ill-treated, neglected or morally abandoned children whose parents have been deprived of their parental rights by the decision of a court of justice, (5) children suffering from diseases of certain crimes, whose parental rights have been delegated by a tribunal to the state. Children classified under 1-5 are termed "enfants soccurs, i.e., children whose parents or relatives are unable, through poverty, to support them; (2) "enfants dépendants, i.e., children under the protection of the state; (3) "enfants en garde, i.e., children who have either committed or been the victim of some felony or crime and are placed under state care by judicial authority. All these children is a departmental (établissement dépositaire), and not a communal institution. The establishment depository usually is usually the ward of an hospital, in which—without the exception of children en déposés—the stay is of the shortest, for by the law of 1904, continuing the principle laid down in 1811, all children under thirteen years of age under the guardianship of the state, except the mentally or physically infirm, are boarded out by the department. They are generally apprenticed to some one engaged in the agricultural industry, and until majority they remain under the guardianship of the administrative commissioners of the department. The state pays a certain amount of money to the employer (domicitaires). Figures show the number of children (exclusive of enfants soccurs) relieved at various periods:

The droit de recette is conceded to the parent on payment of a small fee. The decree of 1811 contemplated the repayment of all expenses by a parent reclaiming a child. The same decree directed a tour or revolving box (Drogeger) to be kept at all hospitals. These were soon discontinued. The "Apostolique de Paris" is managed by a "directeur," appointed by the minister of the interior, and associated with a representative consel of notables. The number of such hospitals is now about 700 beds. There are also in Paris numerous private charities for the adoption of poor children and orphans. It is impossible here to give even a sketch of the long and able controversies which have been conducted in France concerning the legislation of foundling hospitals, the advantages of tours and the system of admission à bureau ouvert, the transfer of orphans from one department to another, the hygiene and care of orphans, and the inspection of nurses, the education and reclamation of the children and the rights of the state in their future. Reference may be made to the works noticed at the end of this article.
support of about 160 children by the "Congregazione di Carità" and about 30 by rich hearts (deputazione fraterna). Austria.—In Austria foundling hospitals occupied a very prominent place in the general instructions by which, rescript dated 16th of April 1781, the emperor Joseph II, issued to the charitable endowments concerning children. The foundling childers are declared to be state institutions. They were accordingly supported by the state treasury under the legal law of 20th October 1848, and the parents had to receive a certificate from the local parishes declaring the child to be "orphan", and the child was then sent to the foundlings' hospital, to which now local institutions, depending on provincial funds, and are quite separate from the ordinary parochial poor institute. Admission is gratuitous when the child is actually found on the street, or is sent by the parents to the hospital a period of four months as nurse or midwife in an asylum, or produces a certificate from the parish priest and "poor-father" (the parish inns are able to the local poor-law administration) that she has no money. In other cases presentation of the child between the ages of one and four months old the child is sent for six or ten years to the houses in the neighbourhood of respectable married persons, who have certificates from the police or the local poor-law administration, and who are inspected by the latter and by a special medical officer. These persons receive a constantly diminishing allowance, and the arrangement may be determined by 14 days' notice on either side. The foster-parents may retain the child in their service or employment till the age of twenty-two, but the true parents may at any time reclaim the foundling on reimbursing the asylum and compensating the foster-parents.

Russia.—Under the old Russian system of Peter I. foundlings were received at the church windows by a staff of women paid by the state. But since the reign of Catherine II. the foundling hospitals have assumed, in the words of the Czarina, "the form of the perekazkas (prykaz obshestvennego pryzrenia)." The great central institutions (Hospitalni Doim), at Moscow and St Petersburg (with a branch at Gatchina), were founded by Catherine. When a child is brought to the hospital a mark is given and, according to the statement of the child's parents, the child may be reclaimed up to the age of ten. The mother may nurse her child. After the usual period of six years in the country very great care is taken with the education, especially of the boys, promising children. The hospital is a valuable source of recruits for the public service. Malthus (The Principles of Population, vol. i. p. 434) has made a violent attack on these Russian charities. He argues that the best course for diminishing the population, and that the best management is unable to prevent a high mortality. He adds: "An occasional child murder from false shame is saved at a price of the sacrifice of some of the best and most useful feelings of the human heart."

It does not appear, however, that the rate of illegitimacy in Russia is comparatively high; it is so in the two great cities. The rights of parents over the children were very much restricted, and those of the government much extended by a ukase issued by the emperor Nicholas in 1817. The most eminent Russian writer on this subject is M. Gourrov. See his Recherches sur les enfants trouvés, and Essai sur l'histoire des enfants trouvés (Paris, 1829).

In America, foundling hospitals, which are chiefly private charities, exist in most of the cities.

Great Britain.—The Foundling Hospital of London was incorporated by royal charter in 1739 "for the maintenance and education of exposed and deserted young children." The petition of Captain Thelwall (1797) to the inhabitants of London, to give a credit to those states as its objects "to prevent the frequent murders of poor miserable children at their birth, and to suppress the inhuman custom of exposing newborn infants, and to place them in the streets. At first no questions were asked about child or parent, but a distinguishing mark was put on each child by the parent. These were often marked coins, trinkets, pieces of cotton or ribbon, verses written on scraps of paper. The clothes, if any, were also recorded. One entry is, "Paper on the breast, clout on the head." The applications became too numerous, and a system of ballotting with red, white and black balls was adopted. In 1756 the House of Commons, to promote the education of the poor, appropriated all the credit of the subscription, and the whole fund of the hospital should be received, that local receiving places should be appointed all over the country, and that the funds should be publicly guaranteed. A basket was accordingly hung outside the hospital; the maximum age for admission was raised from two to twelve months, and the number of children poured in from the country workhouses. In less than four years 14,914 children were presented, and a vile trade grew up among vagrants of undertaking to carry children from the country to the hospital,—an undertaking which, like the French meneurs, they often did not perform or performed with great cruelty. Of these, 1,600 were not adopted. The total expense was about £200,000. This was the first House of Correction in England.

After throwing out a bill which proposed to raise the necessary funds by fees from a general system of parochial registration, they claimed that the introduction of the system should be discontinued. The hospital, being thus thrown on its own resources, was now a charitable institution, adopted a pernicious system of receiving children with considerable sum (e.g. £100), which sometimes led to the children being returned to the parish from which they were taken. The issue of the German Act of 1844 has now a fundamental rule that no money is received. The committee of inquiry must now be satisfied of the previous good character and present necessity of the mother, and that the father of the child will probably replace the mother in the course of virtue and in the way of an honest livelihood. All the children at the foundling hospital, in 1878, were under the age of 2000, and the first children of their mothers. The principle is in fact that laid down by Fielding in Tom Jones—"Too true I am afraid it is that many women have become abandoned and have sunk to the last refinement of vice by the representation that the rich and the hospital supports about 500 children up to the age of fifteen. The average annual number of applications is over 200, and of admissions between 40 and 50. The children used to be named after the days of the week, but are more lately made a list. Children are seldom taken after they are twelve months old. On reception they are sent down to the country, where they stay until they are about four or five years old. At sixteen the girls are generally apprenticed as servants for four years, and the boys at the age of fourteen as mechanics for seven years. There is a small benevolent fund for adults. The musical service, which was originally sung by the blind children only, was made fashionable by the generosity of Handel, who frequently had the "Messiah" performed there, and who bequeathed to the hospital a MS. copy (full score) of it. The Foundling Hospital, in 1828, presented a portrait of Peter Nicol Ross, the founder of the Foundling Hospital. In 1815 a portrait of Captain Coram for the hospital, which also contains a portrait of Miss Abney and a bust of Handel, was purchased by the hospital for £350, a sum of money which Handel had left in his will to the hospital.

The endsowment of the hospital was further increased by a gift of £25,000, by the late Mrs. Abney, a retired schoolmistress and the produce of car licenses. In 1832 an admission fee of £5 was charged on the parish from which the child came. This reduced the annual arrivals to about 500. In 1829 the select committee on the Irish miscellaneous estimates recommended that no further assistance should be given. The hospital had not preserved life or educated the foundlings. The mortality was nearly 4 in 5, and the total cost £10,000 a year. Accordingly in 1835 Lord Glenelg (then Irish Secretary) closed the institution.

Scotland never seems to have possessed a foundling hospital. In 1759 John Watson left funds which were to be applied to the pious and charitable purpose of preventing murders, by the establishment of a hospital for receiving pregnant women and taking care of their children as foundlings. But by an act of parliament in 1822, which sets forth "as to the property" of the hospital. When the houses of parliament were held by a committee for the maintenance and education of destitute children. Authorities.—Histoirte statistique et morale des enfants trouvés by F. de B. In the United States, information is to be found in the Reports on Poor Laws in Foreign Countries, communicated to the Local Government Board by the foreign secretary; Accounts and Papers (1875); vol. iv. c. 1255; Report of Committee on the Infant Life Protection Bill (1890); Report of Lords Committee on the Infant Life Protection Bill (1896). (See also CHARITY AND CHURCHES.)
which consists of a series of basins cut in the solid rock and descending in steps to the stream. The water had been originally led from one to the other by small conduits, the lowest of which was ornamented by two rampant lions in relief. The term is applied equally to the simpler arrangements for letting water gush into an ornamental basin or to the more elaborate ones by which water is mechanically forced into high jets; and a "fountain" may be either the ornamental receptacle or the jet of water itself. In modern times the examples of ornamental or useful fountains are legion, and it will suffice here to mention some of the more important facts of historical interest.

Among the Greeks fountains were very common in the cities. Springs being very plentiful in Greece, little engineering skill was required to convey the water from place to place. Receptacles of sufficient size were made for it at the springs; and to maintain its purity, structures were raised enclosing and covering the receptacle. In Greece they were dedicated to gods and goddesses, nymphs and heroes, and were frequently placed in or near temples. That of Pirene at Corinth (mentioned also by Herodotus) was formed of white stone, and contained a number of cells from which the pleasant water flowed into an open basin. Legend connects it with the nympha Pirene, who shed such copious tears, when bewailing her son who had been slain by Diana, that she was changed into a fountain. The city of Corinth possessed many fountains. In one near the statues of Diana and Bellerophon the water flowed through the hoofs of the horse Pegasus. The fountain of Glauce, enclosed in the temple, was dedicated to Glauce, because she had thrown herself into it believing that its waters could counteract the poisons of Medea. Another Corinthian fountain had a bronze statue of Poseidon standing on a dolphin from which the water flowed. The fountain constructed by Theagenes at Megara was remarkable for its size and decorations, and for the number of its columns. One at Lerna was surrounded with pillars, and the structure contained a number of seats affording a cool summer retreat. Near Pharae was a grove dedicated to Apollo, and in it a fountain of water. Pausanias gives a definite architectural detail when he says that a fountain at Patrae was reached from without by descending steps. Mystical, medicinal, surgical and other qualities, as well as supernatural origin, were ascribed to fountains. One at Cyane in Lycia was said to possess the quality of endowing all persons descending into it with power to see whatever they desired to see; while the legends of fountains and other waters with strange powers to heal are numerous in many lands. The fountain Enneaeranoscopic was at Athens called Calirrhoe because the time the water was drawn from it by the nine pipes from which it took its later name. The fountain of Parnassus, according to Pausanias, was dedicated to Demeter and Persephone, and the other to Triptolemus. The fountain in the temple of Erechtheus at Athens was supplied by a spring of salt water, and a similar spring supplied that in the temple of Poseidon Hippios at Mantinea.

The water-supply of Rome and the works auxiliary to it were on a scale to be expected from a people of such great practical power. The remains of the aqueducts which stretched from the city across the Campagna are amongst the most striking monumental ruins (book viii) give minute particulars concerning the methods by which water was conveyed for the purpose of testing and distribution of water, and describes the properties of different waters with great care, proving the importance which was attached to these matters by the Romans. The aqueducts supplied the baths and the public fountains, from which last all the populace, except such as could afford to pay for a separate pipe to their houses, obtained their water. These fountains were therefore of large size and numerous. They were formed at many of the castella of the aqueducts. According to Vitruvius, each castellum should have three pipes— one for public fountains, one for baths and the third for private houses. Considerable revenue was drawn from the possessors of private water-pipes. The Roman fountains were generally decorated with figures and heads. Fountains were often also the ornament of Roman villas and country houses; in those so situated the water generally fell from above into a large marble basin, with at times a second fall into a still lower receptacle. Two adjacent houses in Pompeii had very remarkable fountains. One, says Gell, "is covered with a sort of mosaic consisting of vitrified tesserae of different colours, but in which blue predominates. These are sometimes arranged in not inelegant patterns, and the grand divisions as well as the borders are entirely formed and ornamented with real sea-shells, neither calcined by the heat of the eruption nor changed by the lapse of so many centuries" (Pompeiana, i. 196). Another of large size was similarly decorated with marble shells, and is supposed to have borne two sculptured figures, one of which, a bronze, is in the museum at Naples. This fountain projects 5 ft. 7 in. from the wall against which it is placed, and is 7 ft. wide in front, while the height of the structure up to the eaves of the pediment is 5 ft. 7 in. On a central column in the piscina was a statue of Cupid, with a dove, from the mouth of which water issued. Cicero had, at his villa at Formiae, a fountain which was decorated with marble shells.

Fountains were very common in the open spaces and at the crossways in Pompeii. They were supplied by leaden pipes from the reservoirs, and had little ornament except a human or animal head, from the mouth of which it was arranged that the water should issue. Not only did simple running fountains exist, but the remains of jets d'eau have been found; and a drawing exists representing a vase with a double jet of water, standing on a pedestal placed in what is supposed to have been a fountain. There was a fountain at the eastern end of the peristyle of the Fullonica at Pompeii.

As among the Greeks, so with the early Celts, traces of superstition beliefs and usages with relation to fountains can be traced in monumental and legendary remains. Near the village of Primaleon in Brittany was a very remarkable monument,—one possibly unique, as giving distinct proof of the existence of an ancient cult of fountains. Here is a dolmen composed of a horizontal table supported by two stones only, one at each end. All the space beneath this altar is occupied by a long square basin formed of large flat stones, which receives a fountain of water. At Lochrist is another vestige of the Celtic cult of fountains. Beneath the church, and at the foot of the hill upon which it is built, is a sacred fountain, near which is erected an ancient chapel, which with its ivy-covered walls has a most romantic appearance. A Gothic vault protects this fountain. Miraculous virtues are still attributed to it, and on certain days the country people still come with offerings to draw it (see La Poix de Fréminville, Antiquités de la Bretagne, i. p. 101). In the enchanted forest of Broceliande, so famous from its connexion with Merlin, was the fountain of Barzamio, which was supposed to have a jet d'eau. Whoever drew water from it, and sprinkled the steps therewith, produced a tremendous storm of thunder and hail, accompanied with thick darkness. Christianity transferred to its own uses the ancient religious feeling concerning fountains. Statues of the Virgin or of saints were erected upon the rude structures that collected the water and preserved its purity. There is some uniformity in the architectural characteristics of these structures during the middle ages. A very common form in rural districts was that in which the fountain was reached by descending steps (step-well); large basins were placed on the steps, from which they were poured from a spout, but often from the spring itself. This basin was covered by a sort of porch or vault, with at times mirrored arches and sculptured figures and escutcheons. On the bank of the Clain at Poitiers is a fountain of this kind, the Fontaine Joubert, which though restored in 1597 was originally a structure of the 14th century. This kind of fountain is frequently decorated with figures of the Virgin or of saints, or with the family arms of its founder; often, too, the water is the only ornament of the structure, which bears a simple inscription. A large number of these fountains are to be found in Brittany and indeed throughout France, and the great antiquity of some of them is proved by the superpositions regarding them which still exist amongst the peasantry. A form more common in populous districts was that of a large open basin, round, square, polygonal, or lobed in
FOUNTAINS ABBEY—FOUQUÉ

form, with a columnar structure at the centre, from the lower part of which it was arranged that spouts should issue, playing into an open basin, and supplying vessels brought for the purpose in the cleanest and quickest manner. The columns take various forms, from that of a simple regular geometrical solid, with only grotesque masks at the spouts, to that of an elaborate and ornate Gothic structure, with figures of virgins, saints and warriors, with mouldings, arches, crockets and finials. At Provins there is a fountain said to be of the 12th century, which is in form an hexagonal vase with a large column in the centre, the fountain columns pierced by three mouths, which are furnished with heads of bronze projecting far enough to cast a spray of water into the basin. In the public market-place at Brunswick is a fountain of the 15th century, of which the central structure is made of bronze. Many fountains are still existing in France and Germany which, though their actual present structure may date no earlier than the 15th or 16th century, have been found on the place of, and perhaps may almost be considered as restorations of, pre-existing fountains. In Italy few fountains are of earlier date than the 14th century. Two of that date are at the rosy lime-planted Daniel, near Mayence, and another, of greater beauty, is at Limbars. Some of these middle-age fountains are simple, open reservoirs enclosed in structures which, however plain, still carry the charm that belongs to the stone-work of those times. There is one of this kind at Cully, Calvados, walled on three sides, and fed from the spring by two circular openings. Its only ornamentation is a small empty niche with mouldings. At Lincoln is a fountain of the time of Henry VIII., in front of the church of St Mary Wickford. At Durham is one of octagonal plan, which bears a statue of Neptune.

The decay of architectural taste in the later centuries is shown by the fountain of Limoges. It is in form a rock representing Mount Parnassus, upon which are carved in relief Apollo, the horse Pegasus, Philosophy and the Nine Muses. At the top Apollo, in the 16th-century costume, plays a harp. Rocks, grass and sheep fill up the scene.

Puriy ornamental fountains and jets d'eau are found in or near many large cities, royal palaces and private seats. The celebrated Fontana di Trevi, at Rome, was erected early in the 18th century under Pope Clement XII., and has all the characteristics of decadence. La Fontana Paolina and those in the piazza of St Peter’s are perhaps the best in celebrity to that of Trevi, and are certainly in better taste. At Paris is the Fontaine de l’Observatoire (the earliest) and those of the Place Royal, of the Champs Elysées and of the Place de la Concorde are the most noticeable. The fountain of the lions and other fountains in the Alhambra palace are, with their surroundings, a very magnificent sight. The largest jets d'eau are those at Versailles, at the Sydenham Crystal Palace and at San Idefonse.

About the earliest drawing of any drinking fountain in England occurs in Moxon’s Tutor to Astronomie and Geographic (1659); it is “surmounted by a dial, which was made by Mr John Leak, and set upon a composite column at Leadenhall corner, in the majority of Sir John Dethick, Knight.” The water springs from the top and base of the column, which stands upon a square pedestal and bears four female figures, one at least of which represents the costume of the period.

In the East the public drinking fountains are a very important institution. In Cairo alone there are three hundred. These “seebels” are not only to be seen in the cities, but are plentiful in the fields and villages.

The Metropolitan Drinking Fountain Association (1859) has done much to provide facilities in London for both man and beast to get water to drink in the streets. And in the United States liberal provision has also been made by public and private enterprise.

FOUNTAINS ABBEY, one of the most celebrated ecclesiastical ruins in England. It lies in the sequestered valley of the river Skell, 3 m. S.W. of the city of Ripon in Yorkshire. The situation is most beautiful. The little Skell descends from the uplands of Pateley Moor to the west a clear swift stream, traversing a valley clothed with woods, conspicuous among which are some ancient yew trees which may have sheltered the monks who first sought retreat here. Steep rocky hills enclose the vale. Mainly on the north side of the stream, in an open glade, rise the picturesque and extensive ruins, the church with its stately tower, and the numerous remnants of domestic buildings which enable the great abbey to be almost completely reconstructed in the mind. The arrangements are typical of a Cistercian house (see ABBEY). Building began in earnest about 1135, and was continued steadily until the middle of the 13th century, after which the only important erection was Abbot Huby’s tower (c. 1500). The dcmesne of Studley Royal (marquess of Ripon’s) is 1 mile to the north of the abbey. The church is in the large Dutch style, the work of John Aislabie, lord of the manor in the early part of the 18th century. Near the abbey is the picturesque Jacobean mansion of Fountains Hall.

In 1132 the prior and twelve monks of St Mary’s abbey, York, being dissatisfied with the easy life they were living, left the monastery and with the assistance of Thurstan, archbishop of York, founded a house in the valley of the Skell, where they adopted the Cistercian rule. While building their monastery the monks are said to have lived at first under an elm and then under the yew trees in the valley. Two years later they were joined by Hugh, dean of St Peter’s, York, who brought with him a large sum of money and a valuable collection of books. His example was followed by Serlo, a monk of St Mary’s abbey, York, and by Tosti, a canon of York, and others. Henry I. and succeeding sovereigns granted them many privileges. During the reign of Edward I. the monks appear to have again suffered from poverty, partly no doubt owing to the invasion of the Scots, but partly also through their own “misconduct and extravagance.” On account of this Edward I. in 1291 appointed John de Berevick custodian of the abbey so that he might pay their debts from the income of their estates, allowing them enough for their maintenance, and Edward II. in 1319 granted them exemption from taxes. After the Dissolution Henry VIII. sold the manor and site of the monastery to Sir Richard Gresham, and from him after passing through several families it came to the markess of Ripon.

See Victoria County History, Yorkshire; Dugdale, Monasticon; Surtees Society, Memorials of the Abbey of St Mary of Fountains, collected and edited by J. R. Walbran (1865-78).

FOUQUÉ, FERDINAND ANDRÉ (1826-1904), French geologist and petrologist, was born at Mortain, dept. of Manche, on the 21st of June 1826. At the age of twenty-one he entered the École Normale in Paris, and from 1853 to 1858 he held the appointment of keeper of the scientific collections. In 1877 he became professor of natural history at the Collège de France, in Paris, and in 1881 he was elected a member of the Academy of Sciences. As a stratigraphical geologist he rendered much assistance on the Geological Survey of France, but in the course of time he gave his special attention to the study of volcanic phenomena and earthquakes, to minerals and rocks; and he was the first to introduce modern petrographical methods into France. His studies of the eruptive rocks of Corsica, Santorin and elsewhere; his researches on the artificial reproduction of eruptive rocks, and his treatise on the optical characters of felspars deserve special mention; but he was perhaps best known for the joint work which he carried on with his friend Michel Lévy. He died on the 7th of March 1904. His chief publications were: Santorin et ses éruptions, 1879; (A. Michael Lévy) Minéralogie micrographique, Roches éruptives françaises (2 vols., 1879); and Synthèse des minéraux et des roches (1882).

FOUQUÉ, FRITZ (1777-1843), German pioneer of the romantic movement, was born on the 12th of February 1777 at Brandenburg. His grandfather had been a Frederick the Great’s generals and his father was a Prussian officer. Although not originally intended for a military career, Friedrich de la Motte Fouqué ultimately gave up his university studies at Halle to join the army, and he took part in the Rhine campaign of 1794. The rest of his life was devoted mainly to literary pursuits. Like so many of the younger romanticists, Fouqué owed his introduction to
literature to A. W. Schlegel, who published his first book, *Dramatische Spiele von Pellegrin* in 1684. His next work, *Romanzen vom Tal Ronceval* (1805), showed more plainly his allegiance to the romantic leaders, and in the *Historie vom edlen Ritter Galmy* (1806) he versified a 16th-century romance of medieval chivalry. *Sigurd der Schlangenläufer, ein Heldenspiel* (1808), the first modern German dramatization of the *Nibelungen*, attracted attention to him, and influenced considerably subsequent versions of the story, such as Hebbel's *Nibelungen* and Wagner's *Ring des Nibelungen*. These early writings indicate the lines which Fouqué's subsequent literary activity followed; his interests were divided between medieval chivalry on the one hand and northern mythology on the other. In 1813, the year of the rising against Napoleon, he again fought with the Prussian army, and the new patriotism awakened in the German people left its mark upon his writings.

Between 1810 and 1815 Fouqué's popularity was at its height; the many romances and novels, plays and epics, which he turned out with extraordinary rapidity, appealed exactly to the mood of the hour. The earliest of these are the best—*Undine*, which appeared in 1811, being, indeed, one of the most charming of all German *Märchen* and the only work by which Fouqué's memory still lives to-day. A more comprehensive idea of his powers may, however, be obtained from the two romances *Der Zauberring* (1813) and *Die Fahrten Thiodulf's der Isländer* (1815). From 1820 onwards the quality of Fouqué's work rapidly degenerated, partly owing to the fatal ease with which he wrote, partly to his inability to keep pace with the changes in German taste. He remained the beloved romanticist, who, as the reading world turned to new interests, clung the more tenaciously to the paraphernalia of romanticism; but in the cold, sober light of the post-romantic age, these appeared merely flimsy and theatrical. The vitalizing imaginative power of his early years deserted him, and the sobriquet of a "Don Quixote of Romanticism" which his enemies applied to him was not unjustified.

Fouqué's first marriage had been unhappy and soon ended in divorce. His second wife, Karoline von Bries (1775–1831) enjoyed some reputation as a novelist in her day. After her death Fouqué married a third time. Some consolation for the ebbing tide of popular favour was afforded him by the munificence of Frederick William IV. of Prussia, who granted him a pension which allowed him to spend his later years in comfort.

He died in Berlin on the 23rd of January 1843.

Fouqué's *Ausgewählte Werke*, edited by himself, appeared in 12 vols. (Berlin, 1841); a selection, edited by M. Koch, will be found in Koch's *Deutsche Nationalliteratur*, vol. 146, part ii. (Stuttgart, 1893); *Undine, Sintram, &c.*, in innumerable reprints. Bibliography in Goedeke's *Gründriss zur Geschichte der deutschen Dichtung* (1872, vi. pp. 152 f.), H. D. Friedel, *In die Geschichte der deutschen Literatur*, pp. 127 f., H. Motz (Fouqué's works have been translated), and the English versions of *Aslauga's Knight* (by Carlyle), *Sintram* and *His Companions* and *Undine*, have been frequently republished. For Fouqué's life cf. *Lebensgeschichte des Baron Friedrich de la Motte Fouqué*. Aufgezeichnet durch den selbst (Halle, 1840), (only to the year 1815), and also the introduction to Koch's selections in the *Deutsche Nationalliteratur*. (J. G. R.)

**FOUQUET** (or **FOUCQUET**), NICOLAS (1615–1680), viscount of Melun and of Vaux, marquis of Belle-Isle, superintendent of finance in France under Louis XIV., was born at Paris in 1615. He belonged to an influential family of the noblesse de la robe, and had a classical education in the Jesuit school. At the age of thirteen was admitted as *avocat* at the parlement of Paris. While still in his teens he held several responsible posts, and in 1636, when just twenty, he was able to buy the post of *maître des requêtes*. From 1642 to 1650 he held various intendancies at first in the provinces and then with the army of Mazarin, and, coming thus in touch with the court, was permitted in 1650 to buy the important position of *procureur général* to the parlement of Paris. During Mazarin's exile Fouquet shrewdly remained loyal to him, protecting his property and keeping him informed of the situation at court.

Upon the cardinal's return, Fouquet demanded and received as reward the office of superintendent of the finances (1653), a position which, in the unsettled condition of the government, threw into his hands not merely the decision as to which funds should be applied to meet the demands of the state's creditors, but also the negotiations with the great financiers who lent money to the king. The appointment was a popular one with the moneyed class, for Fouquet's great wealth had been largely augmented by his marriage in 1651 with Marie de Castille, who also belonged to a wealthy family of the legal nobility. His own credit, and above all his untiring confidence in himself, strengthened the credit of the government, while his high position at the parlement (he still remained *procureur général*) secured financial transactions from investigation. As minister of finance, he soon had Mazarin almost in the position of a suppliant.

The long wars, and the greed of the courtiers, who followed the example of Mazarin, made it necessary at times for Fouquet to meet the demands upon him by borrowing upon his own credit, but he soon turned this confusion of the public purse with his own to good account. The disorder in the accounts became hopeless; rumour and operetta were entered against it with impunity, and the financiers were kept in the position of clients by official favours and by generous aid whenever they needed it. Fouquet's fortune now surpassed even Mazarin's, but the latter was too deeply implicated in similar operations to interfere, and was obliged to leave the day of reconciling to his agent and successor Colbert.

Upon Mazarin's death Fouquet expected to be made head of the government; but Louis XIV. was suspicious of his poorly dissembled ambition, and it was with Fouquet in mind that he made the well-known statement, upon assuming the government, that he would be his own chief minister. Colbert led the king's displeasure, and the reports under the deficit, and made the worst of the case against Fouquet. The extravagant expenditure and personal display of the superintendent served to intensify the ill-will of the king. Fouquet had bought the port of Belle Isle and strengthened the fortifications, with a view to taking refuge there in case of disgrace. He had spent enormous sums in building a palace on his estate of Vaux, which in extent, magnificence, and splendour of decoration was a forecast of Versailles. Here he gathered the rarest manuscripts, the finest paintings, jewels and antiques in profusion, and above all surrounded himself with adorers and flatterers. The table was open to all people of quality, and the kitchen was presided over by Vatel. Lafontaine, Corneille, Scarron, were among the multitude of his clients. In August 1661 Louis XIV., already set upon his destruction, was entertained at Vaux with a fête rivalled in magnificence by one only or two in French history, at which Molière's *Les Fâcheux* was produced for the first time. The splendour of the entertainment sealed Fouquet's fate. The king, however, was afraid to act openly against so powerful a minister. By crafty devices Fouquet was induced to sell his office of *procureur général* to a favourite, who was sent hence to imprisonment in the fortress of Pignerol, where he undoubtedly died on the 23rd of March 1665.1 Louis acted throughout "as though he were conducting a campaign," evidently fearing that Fouquet would play the part of a Richelieu. Fouquet bore himself with manly fortitude, and composed several mediocre translations in prison. The devotional works bearing his name are apocryphal. A report of his trial was published in Holland, in 13 volumes, in 1665–1667, in spite of the remonstrances which Colbert addressed to the States-General. A second edition under the title of *Oeuvres de M. Fouquet* appeared in 1696.

---

1 Fouquet has been identified with the "Man with the Iron Mask" (see *Iron Mask*), but this theory is quite impossible.
FOUQUIER-TINVILLE—FOURIER, F. C. M.

FOUQUIER-TINVILLE, ANTOINE QUINTIN (1746-1795). French revolutionist, was born at Hérouel, a village in the department of the Aisne. Originally a procureur attached to the Châtelet at Paris, he sold his office in 1783, and became a clerk under the lieutenant-general of police. He seems to have early adopted revolutionary ideas, but little is known of the part he played at the outbreak of the Revolution. When the Revolutionary Tribunal of Paris was established on the 10th of July 1793, he was appointed public prosecutor to it, an office which he filled until the 28th of July 1794. His activity during this time earned him the reputation of one of the most terrible and sinister figures of the Revolution. His function as public prosecutor was not so much to convict the guilty as to see that the proscriptions ordered by the faction for the time being in power were carried out with a due regard to a show of legality. He was as ruthless and as incorrupt as Robespierre himself; he could be moved from his purpose neither by pity nor by bribes; nor was there in his cruelty any of that quality which made the ordinary Jacobin enraged by turns ferocious and sentimental. It was this very quality of passionless detachment that made him so effective an instrument of the Terror. He had no forensic eloquence; but the cold obstinacy with which he pressed his charges was more convincing than any rhetoric, and he seldom failed to secure a conviction.

His horrible career ended with the fall of Robespierre and the terrorists on the 9th Thermidor. On the 1st of August 1794 he was imprisoned by order of the Convention and brought to trial. His defence was that he had only obeyed the orders of the Committee of Public Safety; but, after a trial which lasted forty-one days, he was condemned to death, and guillotined on the 27th of May 1795.

See Mémoire pour A. Q. Fouquier ex-accusateur public près le tribunal révolutionnaire, &c. (Paris, 1794); Domenget, Fouquier-Tinville et le tribunal révolutionnaire (Paris, 1875); H. Wallon, Histoire du tribunal révolutionnaire de Paris (1790-1882) (a work of general interest, but not always exact); George Lecocq, Notes et documents sur Fouquier-Tinville (Paris, 1885). See also the documents relating to his trial enumerated by M. Tourneux in Bibliographie française des documents parisiens pendant la Révolution Française, vol. i. Nos. 4445-4454 (1890).

FOURCHAMBALT, a town of central France in the department of Nièvre, on the right bank of the Loire, 43 m. N.W. of Nevers, on the Paris-Lyon railway. Pop. (1906) 4501. It owes its importance to its extensive iron-works, established in 1821, which give employment to 2000 workmen and produce engineering material for railway, military and other purposes. Among the more remarkable chefs-d'œuvre which have been produced at Fourchambault are the metal portions of the Pont du Carrousel, the iron beams of the roof of the cathedral at Chartres, and the vast spans of the bridge over the Dordogne at Cubzac. A small canal unites the works to the Lateral canal of the Loire.

FOURCROY, ANTOINE FRANÇOIS, COMTÉ DE (1755-1809), French chemist, the son of an apothecary in the household of the duke of Orleans, was born at Paris on the 15th of June 1755. He took up medical studies by the advice of the anatomist Félix Vicq d'Azyr (1748-1794), and after many difficulties caused by lack of means finally in 1780 obtained his doctor's diploma. His attention was specially turned to chemistry by J. L. P. Berthollet (1748-1822), professor of chemistry at the Medical School of Paris, and in 1784 he was chosen to succeed P. J. Macquer (1718-1784) as lecturer in chemistry at the college of the Jardin du Roi, where his lectures attained great popularity. He was one of the earliest converts to the views of Lavoisier, which he helped to promulgate by his voluminous writings, but though his name appears on a large number of chemical and also physiological and pathological memoirs, either alone or with others, he was rather a teacher and an organizer than an original investigator. A member of the committees for public instruction and public safety, and later, under Napoleon, director general of instruction, he took a leading part in the establishment of schools for both primary and secondary education, scientific studies being especially provided for. Fourcroy died at Paris on the 16th of December 1809, the very day on which he had been created a count of the French empire. By his conduct as a member of the Convention he has been accused of contributing to the death of Lavoisier. Baron Cuvier in his Histoire de l’empire de Louis XIV repels the charge, but he can scarcely be acquitted of time-serving indifference, if indeed active, though secret, participation be not proved against him. The Royal Society’s Catalogue of Scientific Papers enumerates 59 papers by Fourcroy, and 58 written jointly by him and others, mostly L. N. Vauquelin.

FOURIER, FRANÇOIS CHARLES MARIE (1772-1837), French socialist, was born at Besançon in Franche-Comté on the 7th of April 1772. His father was a draper in good circumstances, and Fourier received an excellent education at the college in his native town. After completing his studies there he travelled for some time in France, Germany and Holland. On the death of his father he inherited a considerable amount of property, which, however, was lost in the Lyons bankruptcy of 1795. Ever since was engaged by order of the Convention in the profession of the Bar; he being deprived of the means of livelihood Fourier entered the army, but after two years' service as a chasseur was discharged on account of ill-health. In 1803 he published a remarkable article on European politics which attracted the notice of Napoleon, some of whose ideas were foreshadowed in it. Inquiries were made after the author, but nothing seems to have come of them. After leaving the army Fourier entered a merchant's office in Lyons, and some years later undertook on his own account a small business as broker. He obtained in this way just sufficient to supply his bare necessities, and devoted all his leisure time to the elaboration of his first work on the organization of society.

During the early part of his life, and while engaged in commerce, he had become deeply impressed with the conviction that social arrangements resulting from the principles of individualism and competition were essentially imperfect and immoral. He proposed to substitute for these principles co-operation or united effort, by means of which full and harmonious development might be given to human nature. The scheme, worked out in detail in his first work, Théorie des quatre mouvements (3 vols., Paris, 1830, published anonymously), is based on a particular psychological proposition and a special economical doctrine. Psychologically Fourier held what may with some laxity of language be called natural optimism,—the view that the full, free development of human nature or the unrestrained indulgence of human passion is the only possible way to happiness and virtue, and that misery and vice spring from the unnatural restraints imposed by society on the gratification of desire. This principle of harmony among the passions he regarded as his grandest discovery—a discovery which did more than set him on a level with Newton, the discoverer of the principle of attraction or harmony among material bodies. Throughout his works, in uncountable and often unintelligible language, he endeavours to show that the same fundamental fact of harmony is to be found in the four great departments,—society, animal life, organic life and the material universe. In order to give effect to this principle and obtain the resulting social harmony, it was needful that society should be reconstructed; for, as the social organism is at present constituted, innumerable restrictions are imposed upon the free development of human wants, and devoted all his leisure time to a reconstruction Fourier advocated co-operative or united industry. In many respects what he says of co-operation, in particular as to the enormous and economic force which the actual arrangements of society entail, still deserves attention, and some of the most recent efforts towards extension of the co-operative method, e.g. to house-keeping, were in essentials anticipated by him. But the full realization of his scheme demanded much more than the mere admission that co-operation is economically more
FOURIER, J. B. J.

efficacious than individualism. Society as a whole must be organized on the lines requisite to give full scope to co-operation and to the harmonious evolution of human nature. The details of this reorganization of the social structure cannot be given briefly, but the broad outlines may be thus sketched. Society, on his scheme, is to be divided into departments or phalanstères, each containing about 1,500 persons. Each phalanstère inhabits a phalanstère or common building, and has a certain portion of soil allotted to it for cultivation. The phalanstères are built after a uniform plan, and the domestic arrangements are laid down very elaborately. The staple industry of the phalanges is, of course, agriculture, but the various series and groupes into which the members are divided may devote themselves to such occupations as are most to their taste; nor need any occupation become irksome from constant devotion to it. Any member of a group may vary his employment at pleasure, may pass from one task to another. The tasks regarded as menial or degrading in ordinary society can be rendered attractive if advantage is taken of the proper principles of human nature: thus children, who have a natural affinity for dirt, and a fondness for "cleaning up," may easily be induced to accept with eagerness the functions of public scavengers. It is not, on Fourier's scheme, necessary that private property should be abolished, nor is the privacy of family life impossible within the phalanstère. Each family may have separate apartments, and there may be richer and poorer members. But the rich and poor are to be locally intermingled, in order that the broad distinctions between them, which is so painful a feature in actual society, may become almost imperceptible. Out of the common gain of the phalange a certain portion is deducted to furnish to each member the minimum of subsistence; the remainder is distributed in shares to labour, capital and talent,—five-twelfths going to the first, four-twelfths to the second and three-twelfths to the third. Upon the changes requisite in the private life of the members Fourier was in his first work more explicit than in his later writings. The institution of marriage, which imposes unnatural bonds on human passion, is to be abolished; a new and ingeniously constructed system of licence is substituted for it. Considerable offence seems to have been given by Fourier's utterances with regard to marriage, and generally the later advocates of his views are content to pass the matter over in silence or to veil their teaching under obscure and metaphorical language.

The scheme thus sketched attracted no attention when the Théorie first appeared, and for some years Fourier remained in his obscure position at Lyons. In 1822 the death of his mother put him in possession of a small sum of money, with which he retired to Bellay in order to perfect his second work. The Traité de l'association agricole domestique was published in 2 vols., at Paris in 1822, and a summary appeared in the following year. After its publication the author proceeded to Paris in the hope that some wealthy capitalist might be induced to attempt the realization of the projected scheme. Disappointed in this expectation he returned to Lyons. In 1826 he again visited Paris, and as a considerable portion of his means had been expended in the publication of his book, he accepted a clerkship in an American firm. In 1829 and 1830 appeared probably the most finished exposition of his views, Le Nouveau Monde industriel. In 1831 he attacked the rival socialist doctrines of Saint-Simon and Owen in the small work Pièges et charlatanismes de deux sectes, St Simon et Owen. His writings now began to attract some attention. A small body of adherents gathered round him, and the most ardent of them was Victor Considerant (q.v.). In 1832 a newspaper, Le Phalanstère ou le refonte industriel was started to propagate the views of the school, but its success was not great. In 1834 it declined from a weekly to a monthly, and in 1835 it died of inanition. It was revived in 1836 as Le Phalange, and in 1838 became a daily paper, La Démocratie pacifique. In 1830 it was suppressed.

Fourier did not live to see the success of his newspaper, and the only practical attempt during his lifetime to establish a phalanstère was a complete failure. In 1832 M. Baudet Dulary, deputy for Scine-et-Oise, who had become a convert, purchased an estate at Conde-sur-Vesgre, near the forest of Rambouillet, and proceeded to establish a socialist community. The capital supplied was, however, inadequate, and the community broke up in disgust. Fourier was in no way discouraged by this failure, and till his death, on the 10th of October 1837, he lived in daily expectation that wealthy capitalists would see the merits of his scheme and be induced to adopt the principles to its realization. It may be added that subsequent attempts to establish the phalanstère have been uniformly unsuccessful. 1

1 Fourier seems to have been of an extremely retiring and sensitive disposition. He mixed little in society, and appeared, indeed, as if he were the denizen of some other planet. Of the true nature of social arrangements, and of the manner in which they naturally grow and become organized, he must be pronounced extremely ignorant. The faults of existing institutions presented themselves to him in altogether distorted manner, and he never appears to have recognized that the evils of actual society are immeasurably less serious than the consequences of his arbitrary scheme. Out of the chaos of human passion he supposed harmony to be to be evolved by the adoption of a few theoretically disputable principles, which themselves impose restraints even more irksome than those due to actual social facts. With regard to the economic aspects of his proposed new method, it is of course to be granted that co-operation is more effective than individual effort, but he has nowhere faced the question as to the probable result of an unorganized society on the abolition of those great institutions which have grown up with us. His temperament was too ardent, his imagination too strong, and his acquaintance with the realities of life too slight to enable him justly to estimate the merits of his fantastic views. That this description of him is not expressed in over-strong language must he clear to any one who not only considers what is true in his works,—and the portion of truth is by no means a peculiar discovery of Fourier's,—but who takes into account the whole body of his speculations, the cosmological and historical as well as the economical and social. No words can adequately describe the fantastic nonsense which he pours forth, partly in the form of general speculation on the universe, partly in the form of prophetic utterances with regard to the future changes in humanity and its material environment. From these extraordinary writings it is no extreme conclusion that there was much of airy fancy in Fourier's mental construction.

FOURIER’S SERIES

753

professor of mathematics in the school in which he had been a pupil. In 1787 he became a novice at the abbey of St Benoît-sur-Loire; but he left the abbey in 1789 and returned to his college, where, in addition to his mathematical duties, he was frequently called to lecture on other subjects,—rhetoric, philosophy and history. On the institution of the École Polytechnique in 1795 he was sent to teach in it, and was afterwards attached to the École Polytechnique, where he occupied the chair of analysis. Fourier was one of the savants who accompanied Bonaparte to Egypt; and during this expedition he was called to discharge important political duties in addition to his scientific ones. He was for a time virtually governor of half Egypt, and for three years was secretary of the Institut du Caire; he also delivered the funeral orations for Kléber and Desaix. He returned to France in 1801, and in the following year he was nominated prefect of Loire, and was created baron and chevalier of the Legion of Honour. He took an important part in the preparation of the famous Description de l’Égypte and wrote the historical introduction. He held his prefecture for fourteen years; and it was during this period that he carried on his elaborate and fruitful investigations on the conduction of heat. On the return of Napoleon from Elba, in 1815, Fourier published a royalist proclamation, and left Grenoble as Napoleon entered it. He was then deprived of his prefecture, and, although immediately named prefect of the Rhône, was soon after again deprived. He now settled at Paris, was elected to the Académie des Sciences in 1816, but in his mathematical researches in Louis XVIII was not admitted till the following year, when he succeeded the Abbé Alexis de Rochon. In 1822 he was made perpetual secretary in conjunction with Cuvier, in succession to Delambre. In 1826 Fourier became a member of the French Academy, and in 1827 succeeded Laplace as president of the council of the École Polytechnique. In 1828 he became a member of the government commission established for the encouragement of literature. He died at Paris on the 16th of May 1830.

As a politician Fourier achieved uncommon success, but his fame chiefly rests on his strikingly original contributions to science and mathematics. The theory of heat engaged his attention quite early, and in 1812 he obtained a prize offered by the Académie des Sciences with a memoir in two parts, Théorie des mouvements de la chaleur dans les corps solides. The first part was republished in 1822 as La Théorie analytique de la chaleur, which by its new methods and great results made an epoch in the history of mathematical and physical science (see below: FOURIER’S SERIES). An English translation has been published by A. Freeman (Cambridge, 1872), and a German by Sciences in 1833. His mathematical publications were also concerned with the theory of equations, but the question as to his priority on several points has been keenly discussed. After his death Navier-completed and published Fourier’s unfinished work, Analyse des équations indéterminées (1831), which contains much original matter. In addition to the works above mentioned, Fourier wrote many memoirs on scientific subjects, and Éloges of distinguished men of science. His works have been collected and edited by Gaston Darboux with the title Oeuvres de Fourier (Paris, 1880–1890).

For a list of Fourier’s publications see the Calculations of Scientific Papers of the Royal Society of London. Reference may also be made to Arago, “Joseph Fourier,” in the Smithsonian Report (1871).

FOURIER’S SERIES, in mathematics, those series which proceed according to sines and cosines of multiples of a variable, the various multiples being in the ratio of the natural numbers; they are used for the representation of a function of the variable for values of the variable which lie between prescribed finite limits. Although the importance of such series, especially in the theory of vibrations, had been recognized by D. Bernoulli, Lagrange and other mathematicians, and had led to some discussion of their properties, J. B. J. Fourier (see above) was the first clearly to recognize the arbitrary character of the functions which the series can represent, and to make any serious attempt to prove the validity of such representation; the series are consequently usually associated with the name of Fourier.

More general cases of trigonometrical series, in which the multiples are given as the roots of certain transcendental equations, were also considered by Fourier.

Before proceeding to the consideration of the special class of series to which our inquiry is directed we define with some precision what is to be understood by the representation of an arbitrary function by an infinite series. Suppose a function of a variable x is given by a series of the form

\[ a_n \cos nx + b_n \sin nx \]

then a and b may be chosen so that the error as between the function and its representation by this series is less than \( e \) between each value of x between a and b; this means that, corresponding to every value of x such that \( a \leq x \leq b \), a definite arithmetical value of the function is assigned by means of some prescribed set of rules. A function so defined by means of rules of this kind is said to be determined by a series of the form \( a_n \cos nx + b_n \sin nx \).

If any number of points between a and b the function may be discontinuous, i.e., it may at such points undergo abrupt changes, it is clear that the number of such points is finite. The only discontinuities hence considered will be those known as ordinary discontinuities. Such a discontinuity exists at the point x if \( f(x+\delta), f(x-\delta) \) have distinct but definite and finite values, where \( \delta \) is an indefinitely small number. The numbers \( f(x+\delta), f(x-\delta) \) are known as the limits on the right and on the left respectively of the function at x, and may be denoted by \( f(x+\delta), f(x-\delta) \).

The discontinuity exists therefore of a sudden change of value of the function, such a discontinuity may be denoted as \( f(x+\delta), f(x-\delta) \)

If there is such a discontinuity at the point \( x=a \), we may denote the limits on the right and on the left respectively by \( f(x+\delta), f(x-\delta) \).

In which case we have an infinite series \( \sum \frac{b_n}{n} \sin nx \) in which each term is a function of x, of known analytical form; let any number \( x-c = a+a=b \) be substituted in the terms of the series, and suppose the sum \( s(x) \) of the series with the value of the function at \( x-c \) is defined for all values of c and \( x-c \) of any value that can be found such that if \( n \neq 0 \), \( |f(x)-S(c)| < \epsilon \).

Functions have also been considered which for an infinite number of points in the interval cease to have a value, and have a sum which does not agree with the value of the function; the series is said to represent "in general" the function for the given interval. If the sum of \( s(x) \) of the terms of the series be denoted by \( S(c) \), the condition that \( S(c) \) converges to the value \( f(x) \) is that, corresponding to any line of negative numbers, or as \( x \) increases indefinitely, the convergence of the series is then infinitely slow in the neighbourhood of such a point, and the series is not uniformly convergent throughout the given interval, although it converges at that point. In such a case it is necessary to consider the sub-intervals in the neighborhood of which the series ceases to converge uniformly be finite, they may be excluded by taking intervals of finite length, as small as we please, and the series, corresponding to the convergence of the series in the given interval with such sub-intervals excluded; the convergence of the series is now uniform throughout the remainder of the interval. The series is said to converge uniformly in general to the sum \( s(x) \) if it can be made uniformly convergent by the exclusion of a finite number of portions of the interval, each such portion being arbitrarily small, and the sum of an infinite series of continuous terms can be discontinuous in the neighbourhood of which the convergence of the series is not...

(2)

We have thus seen, that with the assumptions made, the arbitrary
function /(x) may be represented, for the given interval, either by a
series of sines, as in (i), or by a series of cosines, as in (2).
Some
important differences between the two series must, however, be
noticed. In the first place, the series of sines has a vanishing sum
when x = o or x=/; it therefore does not represent the function at
the point x = o, unless /(o) =o, or at the point x = l, unless /(/)=o,
whereas the series (2) of cosines may represent the function at both
these points. Again, let us consider what is represented by (i) and
(2) for values of x which do not lie between o and /. As/(x) is given
only for values of x between o and /, the series at points beyond these
limits have no necessary connexion with/(x) unless we suppose that
/(x) is also given for such general values of x in such a way that the
series continue to represent that function. If in (i) we change x into
-x, leaving the coefficients unaltered, the series changes sign,
and if x be changed into x+2l, the series is unaltered; we infer that
the series (i) represents an odd function of x and is periodic of

hence the sine series is
\[
\frac{2}{\pi} \left( \frac{1}{1^2} \sin 1 \theta + \frac{1}{3^2} \sin 3 \theta + \frac{1}{5^2} \sin 5 \theta + \cdots \right).
\]

For general values of \(x\), the series represents the ordinates of the row of broken lines in fig. 3.

The cosine series, which represents the same function for the interval \(0 \to 1\), may be found to be
\[
\frac{1}{2} - \frac{2}{\pi} \left( \frac{2}{1^2} \cos 1 \theta + \frac{2}{3^2} \cos 3 \theta + \frac{2}{5^2} \cos 5 \theta + \cdots \right).
\]

This series represents for general values of \(x\) the ordinate of the set of broken lines in fig. 4.

**Fig. 3.**

**Fig. 4.**

**Dirichlet’s Integral.** —The method indicated by Fourier, but first carried out rigorously by Dirichlet, of proving that, with certain restrictions as to the nature of the function \(f(x)\), that function is in general represented by the series (3), consists in finding the sum of \(\pi + 1\) terms of that series, and then investigating the limiting value of the sum, when \(n\) is increased indefinitely. It thus appears that the series is convergent, and that the value towards which its sum converges is \(\frac{1}{2} \int_0^\pi f(x) \sin x dx\), which is in general equal to \(f(\pi)\).

It will be convenient throughout to take \(\pi\) to \(\pi\) as the given interval; any interval \(a \to b\) may be reduced to this by changing \(x\) into \(\pi x\), and thus there is no loss of generality.

We find by an elementary process that
\[
\frac{1}{2} + \cos x - \cos x \left( \frac{2}{1^2} \left( 1 - \cos \frac{x}{2} \right) + \frac{2}{3^2} \left( 1 - \cos \frac{x}{3} \right) + \frac{2}{5^2} \left( 1 - \cos \frac{x}{5} \right) + \cdots \right).
\]

Hence, with the new notation, the sum of the first \(\pi + 1\) terms of (3)
is
\[
\int_0^\pi f(x) \sin x dx = \frac{1}{2} \int_0^\pi f(x) \sin x dx.
\]

If we suppose \(f(x)\) to be continued beyond the interval \(0 \to \pi\), in such a way that \(f(x) = f(x + 2\pi)\), we may replace the limits in this integral by \(x + \pi\), \(x + \pi\) respectively; if we then put \(x = x\), and let \(f(x) = f(x)\), the expression becomes
\[
\int_0^{\pi/2} f(x) \sin x dx.
\]

We require therefore to find the limiting value, when \(n\) is indefinitely increased, of \(\int_0^{\pi/2} f(x) \sin x dx\); the form of the second integral being essentially the same. This integral, or rather the slightly more general one
\[
\int_0^{\pi/2} f(x) \sin 2x dx + \frac{1}{n} \int_0^{\pi/2} h(x) \sin 2x dx,
\]
and suppose as \(x\) increases beyond the value \(M_{n+1}\), \(\psi(x)\) remains constant until the next minimum \(m_{n+1}\) is reached, when it again becomes variable; we see that \(\psi(x)\) is essentially positive and never diminishes as \(x\) increases.

The Second Mean-Value Theorem. —The limiting value of Dirichlet’s integral may be conveniently investigated by means of a theorem in the integral calculus known as the second mean-value theorem. Let \(a, b\) be two fixed finite numbers such that \(a < b\) and suppose \(f(x), \phi(x)\) are two functions which have finite and determinate values everywhere in the interval except for a finite number of points; suppose further that the functions \(f(x), \phi(x)\) are integrable throughout the interval, and that as \(x\) increases from \(a\) to \(b\) the function \(f(x)\) is monotone, i.e., either never diminishes or never increases; the theorem is that
\[
\int_a^b f(x) dx = \int_a^b \phi(x) dx + (f(b) - f(a)) \frac{b-a}{2}
\]
when \(\epsilon\) is some point between \(a\) and \(b\), and \(f(a), \phi(b)\) may be written for \(f(a + \phi), \phi(b - \phi)\) unless \(a\) or \(b\) is a point of discontinuity of the function \(f(x)\).

To prove this theorem, we observe that, since the product of two integrable functions is an integrable function, \(\int_a^b f(x) \phi(x) dx\) exists, and may be regarded as the limit of the sum of a series
\[
\int_a^b f(x) \phi(x) dx = \sum_{x_0}^{x_n} \int_{x_0}^{x_1} f(x) \phi(x) dx + \cdots + \int_{x_n}^{x_{n+1}} f(x) \phi(x) dx,
\]
where \(x_0 = a, x_n = b\) and \(x_1, x_2, \ldots, x_{n-1}\) are \(n\) intermediate points. We can express \(\phi(x)\) in \((x_1 - x_0)\) in the form \(\psi_1 - \psi_2\), by putting
\[
\psi_1 - \psi_2 = \phi(x) \psi_1(x) dx - \phi(x) \psi_2(x) dx,
\]

Writing \(X_n\) for \(f(x)\), the series becomes
\[
\int_a^b f(x) \phi(x) dx = \sum_{x_0}^{x_n} \int_{x_0}^{x_1} f(x) \phi(x) dx + \cdots + \int_{x_n}^{x_{n+1}} f(x) \phi(x) dx + \int_{x_{n+1}}^{x} f(x) \phi(x) dx.
\]

Now, by supposition, all the numbers \(Y_1, Y_2, \ldots, \psi_n\) are finite, and all the numbers \(X_n - X_{n-1}\) are of the same sign, hence, by a known algebraical theorem the series is equal to \((M(X_n - X_{n-1})) dy + X_n - (X_{n-1})\), where \(M = a\) or \(b\) if \(f(a)\) \(f(b)\), it being assumed that these limits exist and the length of the numbers \(Y_n, Y_n, \ldots, Y_n\). This remains true however many partial intervals are taken, and therefore, when their number is increased indefinitely, and their breadths are diminished indefinitely according to any law, we have
\[
\int_a^b f(x) \phi(x) dx = \int_a^b (f(x) - f(b)) \phi(x) dx + \int_a^b \phi(x) \phi(x) dx
\]
when \(M\) is intermediate between the greatest and least values which \(f(x)\) can have, when \(x\) is in the given integral. Now this integral is a continuous function of its upper limit \(x\) and therefore there is a value of \(x\) in the interval, for which it takes any particular value between the greatest and least values that it has.

There is therefore a value \(\epsilon\) between \(a\) and \(b\), such that \(\psi(x)\) in the mean-value theorem, either never increases or never diminishes as \(x\) increases from \(a\) to \(b\), places a restriction upon the applicability of the theorem. We can, however, show that a function \(f(x)\) which is finite and continuous between \(a\) and \(b\), except for a finite number of ordinary discontinuities, and which only changes from increasing to diminishing or vice versa, a finite number of times, as \(x\) increases from \(a\) to \(b\), may be expressed as the difference of two functions \(f(x), f(x), neither of which ever diminishes as \(x\) passes from \(a\) to \(b\), and that these functions are finite and continuous, except that one or more of them are discontinuous at the points where the given function is discontinuous. Let \(a, b\) be two consecutive points at which \(f(x)\) is discontinuous, consider any point \(x_n\) such that \(a \leq x_n \leq b\), and suppose that at the points \(M_1, M_2, \ldots, M_n, M_{n+1}\) between \(a, b\), \(f(x)\) is a maximum, and at \(m_1, m_2, \ldots, m_{n+1}\) it is a minimum; we shall suppose, for example, that the ascending order of values is \(a, M_1, m_1, M_2, m_2, \ldots, M_{n+1}, m_{n+1}\); it will make no essential difference in the argument if \(m_{n+1}\) comes before \(M_1\) or if \(M_{n+1}\) immediately precedes \(x_n\), \(M_{n+1}\) being then the last minimum.

Let \(\psi(x) = f(x) - f(x + x_0) + f(M_0 - f(x_0)) + \cdots + [f(M_n - f(x_0)) + f((M_{n+1} - f(x_0)) + \cdots)

now let \(x_n\) increase until it reaches the value \(M_{n+1}\) at which \(f(x)\) is again a maximum, then let

\[
\psi(x) = f(x) - f(x + x_0) + f(M_0 - f(x_0)) + \cdots + [f(M_n - f(x_0)) + f((M_{n+1} - f(x_0)) + \cdots

and suppose as \(x\) increases beyond the value \(M_{n+1}\), \(\psi(x)\) remains constant until the next minimum \(m_{n+1}\) is reached, when it again becomes variable; we see that \(\psi(x)\) is essentially positive and never diminishes as \(x\) increases.

Let
\[
\psi(x) = f(x) - f(x + x_0) + f(M_0 - f(x_0)) + \cdots + [f(M_n - f(x_0)) + f((M_{n+1} - f(x_0)) + \cdots
\]
thus \(\psi(x)\) never diminishes, and is alternately constant and variable. We see that \(\psi(x) - x_0\) is continuous as \(x\) increases from \(a\) to \(\beta\), and the function \(\psi(x) - x_0\) is therefore an even function throughout the interval, and that \(x_0\) is a point of discontinuity.
applies to every continuous portion of \(f(x)\), for which the functions \(\psi(x), \chi(x)\) are formed in the same manner; we now take \(f(x) = \psi(x) + f(x+\pi) - \psi(x+\pi)\). Here \(f(x)\) never diminishes as \(x \to 0\), and is discontinuous only where \(f(x)\) is so. If the function \(f(x)\) is a particular class of a class of functions defined and discussed by Jordan, under the name of continuous functions with limited variation \(n\) (functions a variation bounded); in general such functions do not necessarily only a finite number of maxima and minima.

**Proof of the Convergence of Fourier’s Series.**—It will now be shown that a function \(f(x)\) arbitrarily given between the values \(-\pi, +\pi\) has the following properties:

(a) The function is everywhere numerically less than some fixed positive number, and continuous except for a finite number of values of the variable, for which it may be arbitrarily discontinuous.

(b) The function only changes from increasing to diminishing or vice versa, a finite number of times within the interval; this is usually expressed by saying that the number of maxima and minima is finite.

These limitations on the nature of the function are known as Dirichlet’s conditions; it follows from them that the function is integrable throughout the interval.

On these assumptions, we can investigate the limiting value of Dirichlet’s integral; it will be necessary to consider only the case of a function \(F(x)\) which does not diminish as \(x\) increases from \(0\) to \(\frac{1}{2}\pi\), since it has been shown that in the general case the difference of two such functions may be taken. The following lemmas will be required:

1. Since

\[
\int_{\pi}^{2\pi} \frac{\sin mx}{\sin x} \, dx = \frac{1}{\pi} \int_{\pi}^{2\pi} \frac{1}{\sin x} \, dx,
\]

this result holds however large the odd integer \(m\) may be.

2. If \(0 < \alpha < \beta \leq \frac{\pi}{2}\),

\[
\int_{\alpha}^{\beta} \frac{\sin mx}{\sin x} \, dx = \frac{1}{\pi} \int_{\alpha}^{\beta} \sin mx \, dx + \frac{1}{\pi} \int_{\alpha}^{\beta} \sin x \, dx,
\]

where \(\alpha < \beta < \frac{\pi}{2}\), hence

\[
\int_{\alpha}^{\beta} \frac{\sin mx}{\sin x} \, dx < \frac{1}{\pi} \left( \int_{\alpha}^{\beta} \sin x \, dx \right) \leq \frac{1}{\pi} \left( \int_{\alpha}^{\beta} \sin x \, dx \right) + \frac{1}{\pi} \left( \int_{\alpha}^{\beta} \sin x \, dx \right),
\]

a precisely similar proof shows that

\[
\int_{\alpha}^{\beta} \frac{\sin mx}{\sin x} \, dx < \frac{1}{\pi} \left( \int_{\alpha}^{\beta} \sin x \, dx \right),
\]

hence the integrals \(\int_{\alpha}^{\beta} \frac{\sin mx}{\sin x} \, dx, \int_{\alpha}^{\beta} \frac{\sin mx}{\sin x} \, dx\) converge to the limit zero, as \(m\) is indefinitely increased.

3. If \(a < 0\),

\[
\int_{0}^{\pi} \frac{\sin \theta \, d\theta}{\sin x} \]

cannot exceed \(\pi\). For the mean-value theorem

\[
\int_{0}^{\pi} \frac{\sin \theta \, d\theta}{\sin x} = \frac{2}{\pi} \frac{\sin \theta}{\sin x},
\]

in particular if \(\alpha \leq \pi\),

\[
\int_{\alpha}^{\pi} \frac{\sin \theta \, d\theta}{\sin x} = \frac{2}{\pi} \frac{\sin \theta}{\sin x}.
\]

Again

\[
\int_{\alpha}^{\beta} \frac{\sin \theta \, d\theta}{\sin x} = \frac{2}{\pi} \frac{\sin \theta}{\sin x},
\]

therefore

\[
\int_{\alpha}^{\beta} \frac{\sin \theta \, d\theta}{\sin x} \]

increases as \(x\) diminishes, while \(x < \alpha\).

But

\[
\int_{\alpha}^{\beta} \frac{\sin \theta \, d\theta}{\sin x} \]

hence

\[
\int_{\alpha}^{\beta} \frac{\sin \theta \, d\theta}{\sin x} \]

so that \(\mu = \pi\).

Therefore

\[
\int_{\alpha}^{\beta} \frac{\sin \theta \, d\theta}{\sin x} \]

is a finite \(\alpha \leq \beta\).

To find the limit of \(\int_{0}^{\pi} (\sin mx \, dx, we observe that it may be written in the form

\[
F(x) \int_{0}^{\pi} (\sin mx \, dx = \int_{0}^{\pi} F(x) \sin mx \, dx + \int_{0}^{\pi} F(x) - F(0) \sin mx \, dx + \int_{0}^{\pi} \sin mx \, dx.
\]

where \(\mu\) is a fixed number as small as we please; hence if we use lemma (1), and apply the second mean-value theorem,

\[
\int_{0}^{\pi} F(x) \sin mx \, dx = \int_{0}^{\pi} (F(x) - F(0)) \sin mx \, dx.
\]

The limits of the two integrals \(\int_{0}^{\pi} (\sin mx \, dx\) are zero, as \(\alpha\) is indefinitely diminished, then

\[
\int_{0}^{\pi} F(x) \sin mx \, dx = \int_{0}^{\pi} (F(x) - F(0)) \sin mx \, dx.
\]
FOURIER'S SERIES

great n is, are each less than a fixed finite quantity. For writing

\[
\int f(x) \cos nx dx = f(x) + f(-x) + \frac{2f(0)}{\pi} \cos \frac{x}{2}
\]

hence

\[
\int f(x) \cos nx dx = f(x) + f(-x) + \frac{2f(0)}{\pi} \cos \frac{x}{2}
\]

with a similar expression, with \( f(x) \) for \( f(-x) \), \( \xi \) being between \( \pi \) and \( -\pi \); the result then follows at once, and is obtained similarly for the other coefficient.

If \( f(x) \) is infinite at \( x = \epsilon \), and is of the form \( \phi(x) \) near the point \( c \), where \( 0 < K < 1 \), the integral

\[
\int f(x) \cos nx dx = \frac{\cos n(x-h)}{n^2} + \frac{\cos n(h-x)}{n^2} + \frac{1}{2} \int f(x) \sin nx dx
\]

is finite, both the integrals being convergent and of known value. The other integral has a singular property, and we infer that \( n^2 \cos n(x-h), n^2 \cos n(h-x) \) are also real fixed finite numbers.

The Differentiation of Fourier's Series. — If we assume that the differential coefficient of a function \( f(x) \) represented by a Fourier's Series exists, that function \( f(x) \) is necessarily representable by the series obtained by differentiating the terms of the Fourier's Series, such derived series being in fact not necessarily convergent. Stokes has obtained general formulae for finding the series which represent \( f'(x) \) of a series given by the successive differential coefficients of a limited function \( f(x) \). As an example of such formulae, consider the sine series (1); \( f(x) \) is represented by

\[
\frac{1}{\pi} \int f(x) \sin nx dx
\]

on integration by parts we have

\[
f(x) \sin nx dx = - f(x) + f'(x) \cos nx dx + \int f'(x) \sin nx dx
\]

where \( f(x) \) is discontinuous. Hence if \( f(x) \) is represented by the series \( 2a_0 \sin \frac{x}{2}, \) and \( f(x) \) by the

series \( \sum b_n \cos nx \) we have the relation

\[
d_n = \frac{2}{\pi} a_n - \frac{1}{\pi} \int f(x) \cos nx dx = f(0) \cos nx dx + \frac{1}{\pi} \int f'(x) \sin nx dx
\]

only when the function is everywhere continuous, and \( f(x) \), \( f'(x) \) are both zero, is the series which represents \( f(x) \) obtained once by differentiating that which represents \( f(x) \). The form of the coefficient \( d_n \) discloses the discontinuities of the function and of its differential coefficients, for on continuing the integration by parts we find

\[
d_n = \frac{2}{\pi} a_n - \frac{1}{\pi} \int f(x) \cos nx dx = f(0) \cos nx dx + \frac{1}{\pi} \int f'(x) \sin nx dx
\]

where \( A \) are the points at which \( f(x) \) is discontinuous.

HISTORY AND LITERATURE OF THE THEORY

The history of the theory of the representation of functions by series of sines and cosines is of great interest in connexion with the progressive development of the notion of an arbitrary function of a real variable, and of the peculiarities which such a function may possess; the modern views on the foundations of the infinitesimal calculus are due to very extensive extent formed in this connexion (see Function). The representation of functions by these series was first considered in the 18th century, in connexion with the problem of a vibrating cord. Euler and Bernoulli were the first to suggest the possibility of such expansions. In a memoir published in 1747 (Memoirs of the Academy of Berlin, vol. iii.) D'Alembert showed that the ordinate \( y \) at any time \( t \) of a vibrating cord satisfies a differential equation of the form

\[
y + a \frac{\partial^2 y}{\partial x^2} = b \frac{\partial^3 y}{\partial x^3}
\]

where \( x \) is measured along the undisturbed length of the cord, and that with the ends of the cord of length \( l \) fixed, the appropriate solution is \( y = f(at + x) - f(at - x) \), where

\( f \) is a function such that \( f(0) = f(t + 2\pi) \); in another memoir in the same volume he seeks for functions which satisfy this condition.

In the year 1748 (Berlin Memoirs, iv.) Euler, in discussing the problem, gave \( f(x) = a \sin \frac{x}{n} + b \sin \frac{x}{n} \) as a particular solution; and maintained that every curve, whether regular or irregular, must be representable in this form. This was objected to by D'Alembert (1750) and also by Lagrange on the ground that irregular curves are inadmissible. D. Bernoulli (Bernoulli's Memoirs, vol. iv.) based his proof on the suppressed seventh chapter of Euler's physical intuition; his method was criticized by Euler (1753). The question was then considered from a new point of view by Lagrange, in a memoir on the nature of musical sound (Miscellanea Taurinensia, 1749; Oeuvres, vi.), where, while criticizing Euler's method, considers a finite number of vibrating particles, and then makes the number of them infinite; he did not, however, quite fully carry out the determination of the coefficients in Bernoulli's theorem. These mathematicians were hampered by the narrow conception of a function, in which it is regarded as necessarily continuous; a discontinuous function was considered only as a fiction of several different functions. Thus the possibility of the expansion of a broken function was not generally admitted. The first cases in which rational functions are expressed in sines and cosines were given by D'Alembert (Subsidium calculi summatorii, Novi Comm. Petrograd., vol. ii., 1754-1755), who obtained the formula

\[
\int f(x) dx = a \sin x + b \cos x + c x + \ldots
\]

In a memoir presented to the Academy of St Petersburg in 1777, but not published until 1780, Euler gave the method afterwards used by Fourier, of determining the coefficients in the expansions; he remarked that \( f \) is expansible in the form

\[
A + B \cos C x + C \cos D x + \ldots
\]

The second period in the development of the theory commenced in 1807, when Fourier communicated his first memoir on the Theory of Heat to the French Academy. His exposition of the theory is contained in a memoir sent to the Academy in 1811, of which his great treatise the Théorie analytique de la chaleur, published in 1822, is, in the main, a reproduction. Fourier set himself to the research of a general theory of series of the form

\[
\int f(x) \sin nx dx
\]

and was the first fully to grasp the idea that a single function may consist of detached portions given arbitrarily by a graph. He had an accurate conception of the convergence of a series, and although he did not give a formally complete proof that a function with discontinuities is representable by the series, he indicated in particular cases the method of procedure afterwards carried out by Dirichlet. As an exposition of principles, Fourier's work is still worthy of careful perusal by all students of the subject. Poisson's treatment of the subject, which has been adopted in English works (see the Journal de l'École polytechnique, vol. xi., 1820, and vol. xii., 1823, and also his Mémoire, Théorie analytique de la chaleur, 1835), depended upon the equality

\[
\int f(x) dx = \frac{1}{\pi} \int f(a) \sin (x-a) dx + \frac{1}{\pi} \int f(a) \cos (x-a) dx
\]

where \( a \) is an arbitrary constant; the limit of the integral on the left-hand side is evaluated when \( a = \frac{1}{2} \), and found to be \( f(x) + f(-x) \), the right-hand side being called Fourier's Series. The equality of the two limits is then inferred. If the series is assumed to be convergent when \( h = 1 \), by a theorem of Abel's its sum is continuous with the sum for values of \( h \) less than unity, but a proof of the convergence for \( h = 1 \) is requisite for the validity of Poisson's proof; as Poisson gave no such proof of convergence, his proof of the general theorem cannot be accepted. The deficiency cannot be removed except by a process of the same nature as that afterwards applied by Dirichlet. The definite integral has been carefully studied by Schwarz (see two memoirs in his collected works on the integration of the equation \( f(x) = \frac{1}{2 \pi} \int f(x) \sin nx dx \)) who showed that the limiting value of the integral depends upon the manner in which the limit is approached. Investigations of Fourier's Series were also given by M. Biot, and his "Mémoire sur le développement des fonctions en séries périodiques," Mem. de l'Acad., vol. vii., also Oeuvres complètes, vol. vii.; his method, which depends upon a use of complex variables, was accepted, with some modification, as valid by Riemann in his senior dissertation. It may be remarked that there still remain definite sufficient conditions in regard to the nature of a function which is expansible, and found under these conditions the limiting value of the sum of a series of a type analogous to Fourier's, the sum of the series at a point of discontinuity has been criticized by Schlüer (see Crelle's Journal, vol. lix.), and by Du Bois-Reymond (Mathem. Annalen, vol. vii.), who maintained that the sum is really

(E. W. H.)

FOURMIES, a town of northern France, in the department of Nord, on an affluent of the Sambre, 39 m. S.E. of Valenciennes by rail. Pop. (1906) 15,308. It is one of the chief centres in France for the woolen and worsted trade, and produces a great variety of cloths. The glass-works of Fourmies date from 1599, and were the first established in the north of France. Iron was worked in the vicinity, and there are important forges and foundries. Enamel-ware is also manufactured. In 1891 labour troubles brought about military intervention and consequent bloodshed. A board of trade arbitration and a school of commerce and industry are among the public institutions.

FOURMONT, ÉTIENNE (1683-1748), French orientalist, was born at Herbelai, near Saint Denis, on the 23rd of June 1683. He studied at the Collège Mazarin, Paris, and afterwards at the Collège Montaigu, where his attention was attracted to Oriental languages. Shortly after leaving the college he published a "Traduction du commentaire du Rabbin Abraham Aben Ezra sur l'Ecclésiaste". In 1711 Louis XIV. appointed Fourmont to assist a young Chinese, Hoan-ji, in compiling a Chinese grammar. Hoan-ji died in 1716, and it was not until 1733 that Fourmont published "Meditations Sinicae" and in 1742 "Grammatica Sinica". He also wrote Réflexions critiques sur les histoires des anciens peuples (1755), and several dissertations printed in the Mémoires of the Academy of Inscriptions. He became professor of Arabic in the Collège de France in 1715. In 1713 he was elected a member of the French Academy and in 1738 a member of the Royal Society of London, and in 1742 a member of the Royal Society of Berlin. He died at Paris on the 19th of December 1745.

His brother, Michel Fourmont (1690-1746), was also a member of the Academy of Inscriptions, and professor of the Syrian language in the Royal College, and was sent by the government to copy inscriptions in Greece.

An account of Étienne Fourmont's life and a catalogue of his works will be found in the second edition (1747) of his Réflexions critiques.

FOURNET, JOSEPH JEAN BAPTISTE XAVIER (1801-1869), French geologist and metallurgist, was born at Strasbourg on the 15th of May 1801. He was educated at the École des Mines at Paris, and after considerable experience as a mining engineer he was in 1834 appointed professor of geology at Lyons. He was a man of wide knowledge and extensive research, and wrote memoirs on chemical and mineralogical subjects, on eruptive rocks, on the structure of the Jura, the metamorphism of the Western Alps, on the formation of oolithic limestones, on kaolinization and on metalliferous veins. On metallurgical subjects he was a leader, and published observations on the order of sulphatisation of metals (loi de Fournet). He died at Lyons on the 8th of January 1869. His chief publications were: Études sur les dépôts métallifères (Paris, 1834); Histoire de la dolomie (Lyons, 1847); De l'extension des terrains houillers (1885); Géologie lyonnaise (Lyons, 1861).

FOURNIER, PIERRE SIMON (1712-1768), French engraver and typefounder, was born at Paris on the 15th of September 1712. He was the son of a printer, and was brought up to his father's business. After studying drawing under the painter
Colson, he practised for some time the art of wood-engraving, and ultimately turned his attention to the engraving and casting of types. He designed many new characters, and his foundry became celebrated not only in France, but in foreign countries. Notcontent with his practical achievements, he sought to stimulate public interest in his art by the production of various works on the subject. In 1763 he published his Table des proportions qu'il faut observer entre les caractères, which was followed by several other technical treatises. In 1758 he assailed the title of Gutenberg to the honour awarded him as inventor of printing, claiming it for Schöffer, in his Dissertation sur l'origine et les progrès de l'art de graver en bois. This gave rise to a controversy in which Schöffer and Baer were his opponents. 

Fournier's contributions to this debate were collected and reprinted under the title of Traité historique et critique sur l'origine de l'imprimerie. His principal work, however, was the Manuel typographique, which appeared in 2 vols. 8vo in 1764, the first volume treating of engraving and type-founding, the second of printing, with examples of different alphabets. It was the author's design to complete the work in four volumes, but he did not live to execute it. He died at Paris on the 8th of October 1768.

FOURNIER L'HERITIER, CLAUDE (1745-1825), French revolutionist, called "l'Amaricain," was born at Auzon (Hauteloir) on the 21st of December 1745, the son of a poor weaver. He went to America to seek his fortune, and started at San Domingo an establishment for making tobacco (an inferior sort of rum), but lost his money in a fire. Returning to France he threw himself into the Revolution with enthusiasm, and specially distinguished himself as the active part he took in the organization of the popular armed force by means of which the most famous of the revolutionary corps were effected. His influence was principally manifested in the insurrections of the 5th and 6th of October 1789, the 17th of July 1791, and the 20th of June and the 10th of August 1792. He was on bad terms with the majority of the politicians, and particularly with Marat, and spent a great part of his time in prison, all the governments regarding him as an agitator and accusing him of inciting to insurrection. Arrested for the first time for trying to force an entrance into the club of the Cordeliers, from which he had been expelled, he was released, but was in prison from the 12th of December 1793 to the 21st of September 1794, and again from the 9th of March 1795 to the 26th of October 1795. After the attempt on the First Consul in the rue Sainte-Nicaise he was deported to Guiana, but was allowed to return to France in 1800. In 1811, while under surveillance at Auxerre, he was accused of having provoked an émeute against taxes known as the dîme réduction (an inferior sort of tax), and was imprisoned in the Château d'If, where he remained till 1814. On the second restoration of the Bourbons Fournier was confined for about nine months in the prison of La Force. After 1816 he was left unmoledusted, turned royalist, and passed his last years in importing the Restoration government for compensation for his lost property in San Domingo. He died in obscurity.

For further details see preface to F. A. Aulard's edition of Fournier's Mémoires secrets (Paris, 1890), published by the Société de l'histoire de la Révolution.

FOURTOUT, MARIE FRANÇOIS OSCAR BARDY DE (1836-1897), French politician, was born at Ribérac (Dordogne) on the 3rd of January 1836, and represented his native department in the National Assembly after the Franco-German War. There he proved a useful adherent to Thiers, who made him minister of public works in December 1872. He was minister of religion in the cabinet of May 1874, 1875, being the only member of the Right included by Thiers in that short-lived ministry. As minister of education, religion and the fine arts in the reconstructed cabinet of the due de Broglie he had used his administrative powers to subject to the censorship all kinds of libraries and books, and as minister of the interior in Broglie's cabinet in 1877 he resumed the administrative methods of the Second Empire. With a well-known Bonapartist, Baron R. C. F. Reille, as his secretary, he replaced republican functionaries by Bonapartist partisans, reserving a few places for the Legitimists. In the general elections of that year he used the whole weight of officialdom to secure a majority for the Right, to support a clerical and reactionary programme. He accompanied Marshal MacMahon in his tour through southern France, and the presidential manifesto of September, stating that the president could rely only on the Senate should the elections prove unfavourable, was generally attributed to Fourtout. In spite of these efforts the cabinet fell, and a commission was appointed to inquire into their unconstitutional abuse of power. Fourtout was unseated in consequence of the revelations made in the report of the commission. In the Chamber of Deputies Gambetta gave the lie direct to Fourtout's allegation that the republican party opposed every republican principle that was not antiquated. A duel was fought in consequence, but neither party was injured. He was re-elected to the chamber in 1879 and entered the Senate the next year. Failing to secure re-election to the Senate in 1883 he again entered the popular chamber as Legitimist candidate in 1889, but he took no further active part in politics. He died in Paris in 1897.

His works include Histoire de Louis XVI (1840); Histoire de Saint Pie V (1845); Mme Sweetchine, sa vie et ses œuvres (2 vols., 1850); La Question italienne (1860); De la contre-révolution (1876); and Mémoires d'un royaliste (2 vols., 1883).

FOUSSA, or FOSSA, the native name of Cryptoprotaca ferex, a somewhat cat-like or civet-like mammal peculiar to Madagascar, where it is the largest carnivorous animal. It is about twice the size of a cat, and has the head and body covered with a fur of nearly uniform pale brown. Little is known of its habits, except that it is nocturnal, frequently attacks and carries off goats, and especially kids, and shows great ferocity when wounded, on which account it is much dreaded by the natives. An example lived in the London zoological gardens for nearly fourteen years. See Carnivora.

FOWEY (usually pronounced Foy), a seaport and market-town in the Bodmin parliamentary division of Cornwall, England, on the Great Western railway, 25 m. by sea W. of Plymouth. Pop. (1901) 2,258. It lies on the west shore of the picturesque estuary of the river Fowey, close to the water's edge, and sheltered by a screen of hills. Its church of St Nicholas is said to have been built in the 14th century, on the site of a still older edifice dedicated to St Finbar of Cork. It has a fine tower and late Norman doorway. Within are a priest's chamber over the porch, a handsome oak ceiling, a 15th-century pulpit, and some curious monuments and brasses. Place House, adjacent to the church, is a highly ornate Tudor building. A few ancient houses remain in the town. Deep-sea fishing is carried on; Fowey Harbour, now a port of call for a number of vessels, is reached from the town by a road, and is connected with Plymouth by the Plymouth and Dartmouth railway. The River Fowey, which is easy of access in clear weather, will admit large vessels at any state of the tide. St Catherine's Fort, dating from the days of Henry VIII, and now ruined, stands at the harbour's mouth, and once formed the main defence of the town. Opposite the town, and connected with it by Bodeneck Ferry, is the village of Polruan. Its main features are St Saviour's Chapel, with an ancient roofed-stone, and the remains of Hall House, which was garrisoned during the civil wars of the 17th century.

(From Palgrave's History of England, 1897)
FOWL—FOWLER, E.

Fowl (Dan. Fugl, Ger. Vogel), a term originally used in the sense that bird is now, but, except in composition,—as sea-fowl, wild-fowl and the like,—practically almost confined at present to designate the otherwise nameless species which, true or false, dunghills, gather round our barn-doors, or stock our poultry-yards—the type of the genus Gallus of ornithologists, of which four well-marked species are known. The first of these is the red jungle-fowl of the greater part of India, G. farrugineus, called by many writers G. bankiva,—which is undoubtedly the parent stock of all the domestic races (cf. Darwin, Animals and Plants under Domestication, i. pp. 233-240). It inhabits northern India from Sind to Burma and Cochin China, as well as the Malay Peninsula and many of the islands as far as Timor and the Fiji Islands. It occurs on the Himalayas up to the height of 4000 ft., and its southern limits in the west of India proper, according to Jerdon, found on the Raj-peepa hills to the south of the Nerbuda, and in the east near the left bank of the Godavery, or perhaps even farther, as he had heard of its being killed at Cumnum. This species resembles in plumage what is commonly known among poultry-fanciers as the "Black-breasted game" breed, and this is said to be especially the case with examples from the Malay countries, between which and examples from India some differences are observable—the latter having the plumage less red, the ear-lappets almost invariably white, and slate-coloured legs, while in the former the ear-lappets are crimson, like the comb and wattles, and the legs yellowish. If the Malay birds be considered distinct, it is to them that the name G. bankiva properly applies. This species is said to be found in lofty forests and in dense thickets, as well as in ordinary bamboo-jungles, and when cultivated land is near its haunts, it may be seen in the fields after the crops are cut in straggling parties of from 10 to 20. The crow to which the cock gives utterance morning and evening is just like that of the bantam, never prolonged as in most domestic birds. The hen breeds from January to July, according to the locality; and lays from 8 to 12 creamy-white eggs, occasionally scraping together a few leaves or a little dry grass by way of a nest. The so-called G. giganteus, formerly taken by some ornithologists for a distinct species, is now regarded as a tame breed of G. farrugineus or bankiva. The second good species is the grey jungle-fowl, G. sonnerati, whose range begins a little to the northward of the limits of the preceding, and it occupies the southern part of the Indian peninsula, without being found elsewhere. The cock has the end of the shaft of the neck-hackles dilated, forming a borny plate, like a drop of yellow sealing-wax. His call is very peculiar, being a broken and imperfect kind of crow, quite unlike that of G. farrugineus and more like a cackle. The two species where their respective ranges overlap, occasionally interbred in a wild state, and the present readily crosses in confinement with domestic poultry, but the hybrids are nearly always sterile. The third species is the Sinhalese jungle-fowl, G. stanleyi (the G. lafayetti of some authors), peculiar to Ceylon. This also greatly resembles in plumage some domestic birds, but the cock is red beneath, and has a yellow plate on his neck, and purplish-red cheeks and wattles. He has also a singularly different voice, his crow being dissyllabic. This bird crosses readily with tame hens, but the hybrids are believed to be infertile. The fourth species, G. varius (the G. furoctus of some authors), inhabits Java and the islands eastward as far as Flores. This differs remarkably from the others in not possessing hackles, and in having a large unscored comb of red and blue and only a single chin wattle. The predominance of green in its plumage is another easy mark of distinction. Hybrids between this species and domestic birds are often produced, but they are most commonly sterile. Some of them have been mistaken for distinct species, as those which have received the names of G. aenescens and G. tempinici.

Several circumstances seem to render it likely that fowls were first domesticated in Burma or the countries adjacent thereto, and it is the tradition of the Chinese that they received them from the West about the year 1400 B.C. By the Institutes of Manu, the tame fowl is forbidden, though the wild is allowed to be eaten—showing that its domestication was accomplished when they were written. The bird is not mentioned in the Old Testament nor by Homer, though he has Aλλεκτρον (cock) as the name of a man, nor is it figured on ancient Egyptian monuments. Pindar mentions it, and Aristophanes calls it the Persian bird, thus indicating it to have been introduced to Greece through Persia, and it is figured on Babylonian cylinders between the 6th and 7 centuries B.C. It is sculptured on the Lycian vases in the British Museum, on the Sabul (c.f. Dan. Sabul) and E. Blyth remarks (Ibis, 1867; p. 157) that it is there represented with the appearance of a true jungle-fowl, for none of the wild Galli have the upright bearing of the tame breed, but carry their tail in a drooping position. For further particulars of these breeds see Poultry.

FOWLER, CHARLES (1792-1867), English architect, was born at Culleton, Devon, on the 17th of May 1792. After serving an apprenticeship of five years at Exeter, he went to London in 1814, and entered the office of David Laing, where he remained till he commenced practice for himself. His first work of importance was the court of bankruptcy in Basinghall Street, finished in 1821. In the following year he gained the first premium for a design for the new London bridge, which, however, was ultimately built according to the design of another architect. Fowler's other designs for bridges include one constructed across the Dart at Totnes. He was also the architect for the markets of Covent Garden and Hungerford, the new market at Gravesend, and Exeter lower market, and besides several churches he designed Devon lunatic asylum (1845), the London fever hospital (1846), and the hall of the Wax Chandlers' Company, Gresham Street (1853). For some years he was honorary secretary of the institute of British architects, and he was afterwards created vice-president. He retired from his profession in 1853, and died at Great Marlow, Bucks, on the 26th of September 1867.

FOWLER, EDWARD (1632-1714), English divine, was born in 1632 at Westerleigh, Gloucestershire, and was educated at Corpus Christi College, Oxford, afterwards migrating to Trinity College, Cambridge. He was successively rector of Northill, Bedfordshire (1659) and of All Hallows, Bread Street, London (1673), and in 1676 was elected a canon of Gloucester, his friend Henry More, the Cambridge Platonist, resigning in his favour. In 1681 he became vicar of St Giles, Cripplegate, but after four years was suspended for Whiggism. When the Declaration of Indulgence was published in 1682 he successfully influenced the London clergy against reading it. In 1691 he was consecrated bishop of Gloucester and held the see until his death on the 26th of August 1714. Fowler was suspected of Pelagian tendencies, and his earliest book was a Free Discourse in defence of The Practices of Certain Moderate Divines called Latitudinarians (1672). The Design of Christianity, published by him in the following year, in which he laid stress on the moral design of revelation, was criticized by Baxter in his Horum Holines is the Design of Christianity (1671) and by Bunyan in his Defence of the Doctrine of Justification by Faith (1672), the latter describing the Design as "a mixture of Popery, Socinianism and Quakerism," a horrid accusation to which Fowler replied in a scurrilous pamphlet entitled Dirt Wip'd Off. He also published, in 1693, Twenty-Eight Propositions, by which the Doctrine of the Trinity is endeavoured to be explained, challenging with some success the Socinian position.

1 Bird (congnate with breed and broad) was originally the young of any animal, and an early Act of the Scottish parliament speaks of "Wolf-birds," i.e. Wolf-cubs.

2 Like Deer (Dan. Dyr, Ger. Tier). Beast, too, with some men has almost attained as much specialization.
FOWLER, J.—FOX, C. J. 761

FOWLER, JOHN (1826–1864), English inventor, was born at Melksham, Wilts, on the 11th of July 1826. He learned practical engineering at Middlesborough-on-Tees, and about 1850 invented a mechanical system for the drainage of land. In 1851 he became a pupil of John Trowler Leather, the engineer of the Sheffield waterworks. The latter's uncle, George Leather, was engineer of the Great Aire and Calder Navigation Company, of the Goole Docks, and other similar works, and Fowler passed occasionally into his employment, in which he acquired a thorough knowledge of hydraulic engineering. The era of railway construction soon swept both Fowler and his employers into its service, and one of his first employments was to oppose the route of the Midland railway, chosen by the Stephenson line, which left Sheffield on a branch line, and was therefore strongly resented by the inhabitants. The prestige of the Stephenson's carried all before it, but later Fowler laid down the small railway systems which eventually were amalgamated under the title of the Manchester, Sheffield & Lincolnshire. In the course of this work he designed a bridge known as Torksey Bridge, which was disallowed by the Board of Trade inspector, Captain (afterwards Field-Marshal Sir) Lintorn Simmons. The engineering profession espoused Fowler's side in the controversy which followed, and as a result the verdict of the Board of Trade was modified. The episode was the beginning of a warm friendship between these distinguished repugnant to civil and military engineering. Fowler was engineer of the London & Southend, and later of the French underground railways, and noteworthy in that it was mostly made not by tunnelling, but by excavating from the surface and then covering in the permanent way; and he lived to be one of the engineers officially connected with the deep tunnelling "tube" system extensively adopted for electric railways in London. He was also engaged in the making of railways in Ireland, and in 1867 he was selected by D'Arcy to serve on a commission to advise the government in respect of a proposal for a state-purchase of the Irish railway system. He also carried out considerable works in connection with the improving the drainage of territory land at the Norfolk estuary.

In 1865 he was elected president of the Institution of Civil Engineers, the youngest president who had ever sat in the chair. He was strongly opposed to the project of a Channel tunnel to France, and in 1872 he endeavoured to obtain the consent of parliament to a Channel ferry scheme, whereby trains were to be transported across the strait in large ferry steamers. The proposal involved the making of enlarged harbours at Dover and Audresselles in connection with the French coast, and the bill, after passing the Commons, was thrown out in the House of Lords by the vote of the chairman of a committee of the House of Lords. In 1872 he was enabled to render, in his private capacity, a signal service to the Italian government, which was much embarrassed by impracticable proposals pressed on it by Garibaldi for a rectification of the course of the Tiber and other engineering works. He had several interviews with the Italian patriot, and persuaded him of the impracticable nature of his plan, thereby obtaining for the government leisure to devise a more reasonable scheme. For eight years from 1871 he acted as general engineering adviser to Egypt and the Khedive Ismail. He projected a railway to the Sudan, and also the great Aswan dam. In a variety of other plans came to an end owing to financial reasons. But the maps and surveys for the railway were given to the war office, and proved most useful to Lord Woseley in his Nile expedition. For his service Fowler was made K.C.M.G. (1883). He was created a baronet in 1890 on the completion of the Forth bridge, of which with his partner Sir Benjamin Baker he was joint engineer. He died at Bournemouth on the 20th of November 1898.

FOWLER, WILLIAM (c. 1562–1614), Scottish poet, was born about 1560. He attended St. Leonard's College, St Andrews, between 1574 and 1578, and in 1581 he was in Paris studying civil law. In 1581 he issued a pamphlet against John Hamilton and other Catholics, who had, said, driven him from his country. He subsequently (about 1590) became private secretary and Master of Requests to Anne of Denmark, wife of James VI, and was denounced to these offices when the queen went to England. In 1609 his services were rewarded by a grant of 2000 acres in Ulster. His sister Susannah Fowler married Sir John Drummond, and was mother of the poet William Drummond of Hawthornden. On the title-page of "The Triumphs of Petrarch, Fowler styles himself "P. of Hawick," which has been held to mean that he was parson of Hawick, but this is doubtful. A MS. collection of seventy-two sonnets, entitled The Tarantula of Love, and a translation (1587) from the Italian of the Triumphs of Petrarch are preserved in the library of the university of Edinburgh, in the collection bequeathed by his nephew, William Drummond. Two other volumes of his manuscript notes, scrolls of poems, &c., are preserved among the Drummond MSS., now in the library of the Society of Antiquaries of Scotland. Specimens of Fowler's verses were published in 1863 by John Leyden in his Scottish Descriptive Poems. Fowler contributed a prefatory sonnet to James VI's Furies; and James, in return, commended, in verse, Fowler's Triumphs.

FOX, CHARLES JAMES (1749–1806), British statesman and orator, was the third son of Henry Fox, 1st Lord Holland, and his wife, Lady Caroline Lennox, eldest daughter of Charles Lennox, 2nd Duke of Richmond. He was born at 9 Conduit Street, Westminster, on the 24th of January 1749. The father, who treated his children with extreme indulgence, allowed him to choose his school, and he elected to go to one kept at Wadsworth, and on Sundays he was allowed to go into the town to curry its own. At 17 he went to Eton, where he went in 1757. At Eton he did no more work than was acceptable to him, but he had an innate love of literature, and he laid the foundation of that knowledge of the classic languages which in after years was the delight of his life. The vehemence of his temper was controlled by an affectionate disposition. When quite a boy he checked his own tendency to fits of passion on learning that his father trusted him to cure his defects.

That he learnt anything, and that he grew up an amiable and modest person, was due to his natural worth, for no one ever owed less to education or to family example. The relations of Lord Holland to his sons would be difficult to parallel. He not only treated them, and in particular Charles, as friends and companions in pleasure from the first, but he did his best to encourage them in dissipation. In 1763 he took Charles for a tour on the continent, introduced him to the most immoral society of the time and gave him money with which to gamble. The boy came back to Eton a precocious rake. It was his good fortune that he did go back, for he was subjected to a wholesome course of ridicule by the other boys, and was dogged by Dr Barnard, the headmaster. In 1764 Charles proceeded to Hertford College, Oxford. At Oxford, as at Eton, he read literature from natural liking, and he paid some attention to mathematics. His often quoted saying that he found mathematics entertaining was probably meant as a jest at the expense
of Sir G. Macartney, to whom he was writing, and who was known to maintain that it was useless. His own account of his school and college training, given in a letter to the same correspondent (6th August 1767), is: "I employed almost my whole time at Oxford in the mathematical and classical knowledge, but more particularly in the latter, so that I understand Latin and Greek tolerably well. I am totally ignorant in every part of useful knowledge. I am more convinced every day how little advantage there is in being at school and the university as a good scholar: one receives a good deal of amusement from it, but that is all. At present I read nothing but Italian, which I am immediately fond of, particularly of the poetry. . . . As for French, I am far from being so thorough a master of it as I could wish, but I know so much of it that I could perfect myself in it at any time with very little trouble, especially if I pass three or four months in France." The passage is characteristic. It shows at once his love of good literature and his thoroughness. Fox's youth was disorderly, but it was never indolent. He was incapable of half doing anything which he did at all. He did perfect himself in French, and he showed no hesitancy to determine to master more sports. At a later period when he had grown fat he accounted for his skill in taking "cut balls" at tennis by saying that he was a very "painstaking man." He was all his life a great and steady walker.

The disorders of his early years were notorious, and were a common subject of gossip. In the spring of 1767 he left Oxford and joined his father on the continent during a tour in France and Italy. In 1768 Lord Holland bought the pocket borough of Midhurst for him, and he entered on his parliamentary career, and on London society, in 1769. Within the next few years Lord Holland reaped to the full the reward for all that was good, and whatever was evil, in the training he had given his son. The affection of Charles Fox for his father was unbounded, but the passion for gaming which had been instilled in him as a boy proved the ruin of the family fortune. He kept racehorses, and bet on them largely. On the racecourse he was successful, and it is another proof of his native thoroughness that he gained a reputation as a handicapper. It is said that he won more than he lost on the course. At the gambling table he was unfortunate, and there can be little question that he was debased both in London and in Paris by unscrupulous players of his own social rank, who took advantage of his generosity and whose worthlessness he knew. In the ardour of his passion Fox took his losses and their consequences with an attractive gaiety. He called the room in which he did business with the Jew money-lenders his "Jerusalem chamber." When his elder brother had a son, and his prospects were injured, he said that the boy was a second Messiah, who had appeared for the destruction of the Jews. "He had his jest, and they had his estate." In 1774 Lord Holland had to find £40,000 to pay the gambling debts of his sons. For years Charles lived in pecuniary embarrassment, and during his later years, when he had given up gambling, he was supported by the contributions of wealthy friends, who in 1793 formed a fund of £70,000 for his benefit.

His public career did not supply him with a check on habits of dissipation in the shape of the responsibilities of office. He began, as was to be expected in his father's son, by supporting the court; and in 1770, when only twenty-one, he was appointed a junior lord of the admiralty with Lord North. During the violent conflict over the Middlesex election (see Wilkes, John) he took the unpopular side, and vehemently asserted the right of the House of Commons to exclude Wilkes. In 1772 during the proceedings against Crosby and Oliver—a part of the "Wilkes and liberty" agitation—he and Lord North were attacked by a mob and rolled in the mud. But Fox's character was incompatible with ministerial service under King George III. The king, himself a man of orderly life, detested him as a gambler and was too independent to please a master who expected obedience. In February 1773 he threw in his office. He had no place to be free to oppose the Royal Marriage Act, on which the king's heart was set. He returned to office as junior lord of the treasury in December. But he was insubordinate; his sympathy with the American colonies, which were now beginning to resist the claims of the mother country to tax them, made him intolerable to the king and he was dismissed in February 1774. The death of his father on the 1st of July of that year removed an influence which tended to keep him subordinate to the court, and his friendship for Burke drew him into close alliance with the Rockingham Whigs. From the first his ability had won him admiration in the House of Commons. He had prepared to distinguish himself as an orator by the elaborate cultivation of his voice, which was naturally harsh and shrill. His argumentative force was recognized at once, but the full scope of his powers was first shown on the 2nd of February 1775, when he spoke on the disputes with the colonies. The speech is unfortunately lost, but Gibbon, who heard it, told his friend Holroyd (afterwards Earl of Sheffield) that Fox, "taking the vast compass of the question before us, discovered powers for regular debate which neither his friends hoped nor his enemies dreaded."

His great political career dates from that day. It is unique among the careers of British statesmen of the first rank, for it was passed almost wholly in opposition. Except for a few months in 1782 and 1783, and again for a few months before his death in 1806, he was out of office. If he was absolutely sincere in the statement he made to his friend Fitzpatrick, in a letter of the 3rd of February 1778, his life was all he could have wished. "I am," he wrote, "certainly ambitious by nature, but I really have, or think I have, totally subdued that passion. I have still as much vanity as ever, which is a happier passion by far, because great reputation I think I may acquire and keep, great situation I never can acquire, nor if acquired keep, without making sacrifices that I never will make." His words show that he judged himself and read the future accurately. Yet it was certainly a cause of bitter disappointment to him that he had to stand by while the country was in his opinion not only misgoverned, but led to ruin. His reputation as an orator and a political critic, which was great from the first and grew as he lived, most assuredly did not console him for his impotence as a statesman. Of the causes which rendered his brilliant capacity useless for the purpose of obtaining practical success the most important, perhaps the only one of real importance, was his personal character. Lord John Russell (afterwards Earl Russell), his friendly biographer, has to confess that Fox might have joined in the confession of Mirabeau: "The public cause suffers for the immoralities of my youth." His reputation as a rake and gambler was so well established at the very beginning of his career that when he was dismissed from office in 1774 there was a general belief among the vulgar that he had been detected in actual theft. His perfect openness, the notoriety of his bankruptcies and of the seizure of his books and furniture in execution, kept him before the world as a model of dissipation. In 1772 when he was leading the resistance to Lord North's colonial policy, he "neither abandoned gaming nor his rakish life. He was seldom in bed before five in the morning nor out of it before two at noon." At the most important crisis of his life in 1783, he almost made an ostentation of disorder and of indifference not only to appearances, but even to decency. Horace Walpole has drawn a picture of him at that time which Lord Holland, Fox's beloved and admiring nephew, speaking from his early recollections of his uncle, confesses has "some justification." Coming from such an authority the certificate may be held to confirm the substantial accuracy of Walpole. "Fox lodged in St. James's Street, and as soon as he rose, which was very late, had a levee of his followers and of the gaming club at Brooks's—all his disciples. His bristly black person, and shagged breast quite open and rarely purified by any ablations, was wrapped in a foul linen nightgown and his bushy hair dishevelled. In these cynic weeds and with Epicurean good humour did he dictate his politics, and in this school did the heir of the empire attend his lessons and be taught them. That this cynic manner, and Epicurean speech, were only the outside of a manly and generous nature was well known to the personal friends of Fox, and is now universally allowed. But by the bulk of his contemporaries,
who could not fail to see the weaknesses he ostentatiously displayed, Fox was, not unnaturally, suspected as being immoral and untrustworthy. Therefore when he came into collision with the will of the king he failed to secure the confidence of the nation which was his only support. Nor ought any critical admirer of Fox to deny that George III, was not wholly without faults, he said that the great orator "was totally destitute of discretion and sound judgment." Fox made many mistakes, due in some cases to vehemence of temperament, and in others only to be ascribed to want of sagacity. That he fought unpopular causes is a very insufficient explanation of his failure as a practical statesman. He could have profited by the reaction which followed popular excitement but for his bad reputation and his want of discretion.

During the eight years between his expulsion from office in 1776 and the fall of Lord North's ministry in March 1782 he may indeed be said to have done one very great thing in politics. He planted the seed of the modern Liberal party as opposed to the pure Whigs. In political allegiance he became a member of the Rockingham party and worked in alliance with the marquis and with Burke, whose influence on him was great. In opposing the attempt to coerce the American colonists, and in assailing the waste and corruption of Lord North's administration, as well as the undue influence of the crown, he was at one with the Rockingham Whigs. During the agitation against corruption, and the more violent movement which was conducted with the most vigorous spirit of fiscal economy, Fox made himself very strong between 1779 and 1782, and he and they worked heartily together. It had a considerable effect, and prepared the way for the reforms begun by Burke and continued by Pitt. But if Fox learnt much from Burke he learnt with originality. He declined to accept the revolution settlement as final, or to think with Burke that the constitution of the House of Commons could not be bettered. Fox acquired the conviction that, if the House was to be made an efficient instrument for restraining the interference of the king and for securing good government, it must cease to be filled to a very large extent by the nominees of boroughmongers and the treasury. He became a strong advocate for parliamentary reform. In all ways he was the ardent advocate of what have in later times been known as "Liberal causes," the removal of all religious disabilities and tests, the suppression of private interests which hampered the public good, the abolition of the slave trade, and the emancipation of all classes and races of men from the strict control of authority.

A detailed account of his activity from 1774 to 1782 would entail the mention of every crisis of the American War of Independence and of every serious debate in parliament. Throughout the struggle Fox was uniformly opposed to the coercion of the colonies and was the uniting critic of Lord North. While the result must be held to prove that he was right, he prepared future difficulties for himself by the fury of his language. He was the last man in the world to act on the worldly-wise maxim that an enemy should always be treated as if he may one day be a friend, and a friend as if he might become an enemy. On the 19th of November 1779 Fox was wounded in a duel with Mr William Adam, a supporter of Lord North's whom he had savagely denounced. He assailed Lord North with unmeasured invective, directed not only at his policy but at his personal character, though he well knew that the prime minister was an amiable though pliable man, who remained in office against his own wish, in deference to the king who appealed to his loyalty. When the disasters of the American war had at last made a change of ministry necessary, and the king applied to the Whigs, through the intermediary of Lord Shelburne, Fox made a very serious mistake in persuading the marquis of Rockingham to insist on dealing directly with the sovereign. The result was the formation of a cabinet belonging, in Fox's own words, partly to the king and partly to the country—that is to say, partly of Whigs who wished to restrain the king, and partly of the king's friends, represented by Lord Shelburne, whose real function was to baffle the Whigs. Dissensions began from the first, and were peculiarly acute between Shelburne and Fox, the two secretaries of state. The old division of duties by which the southern secretary had the correspondence with the colonies and the western powers of Europe, and the northern secretary with the others, had been abolished on the formation of the Rockingham cabinet. All foreign affairs were entrusted to Lord Shelburne. The minister meditated the conclusion of a peace at Paris. He also persuaded his colleagues to grant some rather scandalous pensions, and Fox's acquiescence in this abuse after his recent agitation against Lord North's waste did him injury. When the marquess of Rockingham died on the 1st of July 1782, and the king offered the premiership to Shelburne, Fox resigned, and was followed by a part of the Rockingham Whigs.

In refusing to serve under Shelburne he was undoubtedly consistent, but his next step was ruinous to himself and his party. On the 14th of February 1783 he formed a coalition with Lord North, based as they declared on "mutual goodwill and confidence." Plausible excuses were made for the alliance, but to the country at large this union, formed with a man whom he had denounced for years, had the appearance of an unscrupulous conspiracy to obtain office on any terms. In the House of Commons the coalition was strong enough to drive Shelburne from office on the 24th of February. The king made a prolonged resistance to the pressure put on him to accept Fox and North as his ministers (see Pitt, William). On the 22nd of April he was constrained to submit to the formation of a new ministry, in which the duke of Portland was prime minister and Fox and North were secretaries of state. The new administration was ill liked by some of the followers of both. Fox increased its unpopularity both in the House and in the country by consenting against the wish of most of his colleagues to ask for the grant of a sum of £100,000 a year to the prince of Wales. The act had the appearance of a deliberate offence to the king, who was on bad terms with his son. The magnitude of the sum, and his acquiescence in the grant of pensions by the Shelburne ministry, confirmed the charge of corruption forwarded by the-Whigs. The introduction of the India Bill in November 1783 alarmed many vested interests, and offended the king by the provision which gave the patronage of India to a commission to be named by the ministry and removable only by parliament. The coalition, and Fox in particular, were assailed in a torrent of most telling invective and caricature. Encouraged by the growing unpopularity of his ministers, George III, gave it to be understood that he would not look upon any member of the House of Lords who voted for the India Bill as his friend. The bill was elected for the upper House on the 17th of December, and next day the king dismissed his ministers.

Fox now went into opposition again. The remainder of his life may be divided into four portions—his opposition to Pitt during the session of 1784; his parliamentary activity till his secession in 1797; his retirement till 1800; his return to activity and his short tenure of office before his death in 1806. During the first of these periods he deepened his unpopularity by assailing the undoubted prerogatives of the crown, by claiming for the House of Commons the right to override not only the king and the Lords but the opinion of the country, and by resisting a dissolution. This last pretension was so very ill from a statesman who in 1780 had advocated yearly elections. He lost ground daily before the steady good judgment and unblemished character of Pitt. When parliament was dissolved at the end of the session of 1784, the country showed its sentiments by unseating 180 of the followers of Fox and North. Immense harm was done to both by the publication of a book called The Beauties of Fox, North and Burke, a compilation of their abuse of one another in recent years.

Fox himself was elected for Westminster with fewer votes than Admiral Lord Hood, but with a majority over the ministerial candidate, Sir Cecil Wray. The election was marked by an amazing outflow of caricatures and squibs, by weeks of rioting in which Lord Hood's sailors fought pitched battles in St James's Street with Fox's hackney coachmen, and by the intrepid canvassing of Whig ladies. The beautiful duchess of Devonshire
(Georgiana Spencer) is said to have won at least one vote for Fox by kissing a shoemaker who had a romantic idea of what constituted a desirable bribe. The high bailiff refused to make a return, and the confirmation of Fox's election was delayed by the somewhat mean action of the ministry. He had, however, been chosen for Kirkwall, and could fight his cause in the House. In the end he recovered damages from the high bailiff. In his place in parliament he sometimes supported Pitt and sometimes opposed him with effect. His criticism on the ministers' bill for the government of India was sound in principle, though the evils he foresaw did not arise. Little excuse can be made for his opposition to Pitt's commercial policy towards Ireland. But as Fox on this occasion aided the vested interests of some English manufacturers he secured a certain revival of popularity. His support of Pitt's Reform Bill was qualified by a just dislike of the ministers' proposal to treat the possession of the franchise by a constituency as a property and not as a trust. His unsuccessful opposition to the commercial treaty with France in 1787 was unwise and most injurious to himself. He committed himself to the proposition that France was the natural enemy of Great Britain, a saying often quoted against him in coming years. It has been excused on the ground that when he said France he meant the aggressive house of Bourbon. A statesman whose words have to be interpreted by an esoteric meaning cannot fairly complain if he is often misunderstood. In 1788 he travelled in Italy, but returned in haste on hearing of the illness of the king. Fox supported the claim of the prince of Wales to the regency as a right, a doctrine which provoked Pitt into declaring that he would "unwittingly go to the grave with the rest of his life." The friendship between him and the prince of Wales (see George IV.) was always injurious to Fox. In 1787 he was misled by the prince's ambiguous assurances into denying the marriage with Mrs Fitzherbert. On discovering that he had been deceived he broke off all relations with the prince for a year, but their alliance was renewed. During these years he was always in favour of whatever measures could be described as favourable to emancipation and to humanity. He actively promoted the impeachment of Warren Hastings, which had the support of Pitt. He was always in favour of the abolition of the slave trade (which he actually effected during his short tenure of office in 1806), of the repeal of the Test Acts, and of concessions to the Roman Catholics, both in Great Britain and in Ireland.

The French Revolution affected Fox profoundly. Together with almost all his countrymen he welcomed the meeting of the states-general in 1789 as the downfall of a despotism hostile to Great Britain. But when the development of the Revolution caused a general reaction, he adhered stoutly to his opinion that the revolution was essentially just and ought not to be demanded for its errors or even for its crimes. As a natural consequence he was the steady opponent of Pitt's foreign policy, which he condemned as a species of crusade against freedom in the interest of despotism. Between 1790 and 1800 his unpopularity reached its height. He was left almost alone in parliament, and was denounced as the enemy of his country. On the 6th of May 1791 occurred the painful scene in the House of Commons, in which Burke renounced his friendship. In 1792 there was some vague talk of a coalition between him and Pitt, which came to nothing. It should be noted that the scene with Burke took place in the course of the debate on the Quebec Bill in which Fox displayed real statesmanship by criticizing the division of Upper from Lower Canada, and other provisions of the bill, which in the end proved so injurious as to be unworkable. In this year he carried the Lieb Bill. In 1792 his ally, the duke of Portland, and most of his party left him. In 1797 he withdrew from parliament, and only came forward in 1798 to reaffirm the doctrine of the sovereignty of the people at a great Whig dinner. On the 9th of May he was dismissed from the privy council.

The interval of secession was perhaps the happiest in his life. In 1783 he formed a connexion with Elizabeth Bridget Cave, commonly known as Mrs Armstead or Armistead, an amiable and well-mannered woman to whom he was passionately attached. In company with her he established himself at St Anne's Hill near Chertsey in Surrey. In 1795 he married her privately, but did not avow his marriage till 1802. In his letters he spoke of her always as Mrs Armistead, and of some of his friends—Mr Coke of Holkham, afterwards Lord Leicester, with whom he stayed every year, being one of them—would not invite her to their festivities. It is hard to explain this solitary instance of shabby conduct in a thoroughly generous man towards a person to whom he was unalterably attached and who fully deserved his affection. Fox's time at St Anne's was largely spent in gardening, in the enjoyment of the country, and in correspondence on literary subjects with his nephew, the 3rd Lord Holland, and with Gilbert Wakefield, the editor of Euripides. His letters show that he had a very sincere love for, and an enlightened appreciation of, good literature. Greek and Italian were his first favourites, but he was well read in English literature and in French, and acquired some knowledge of Spanish. His favourite authors were Euripides, Virgil and Racine, whom he defends against the stock criticisms of the admirers of Corneille with equal zeal and insight.

Fox reappeared in parliament to take part in the vote of censure on ministers for de-nailing Napoleon's overtures for a peace. The fall of Pitt's first ministry and the formation of the Addington cabinet, the peace of Amiens, and the establishment of Napoleon as first consul with all the powers of a military despot, seemed to offer Fox a chance of resuming power in public life. The struggle with Jacobinism was over, and he could hazard in supposing resistance to a successful general who ruled by the sword, and who pursued a policy of perpetual aggression. During 1802 he visited Paris in company with his wife. An account of his journey was published in 1811 by his secretary, Mr Trotter, in an otherwise poor book of reminiscences. It gives an attractive picture of Fox's good-humour, and of his enjoyment of the "species of minor comedy which is constantly exhibited in common life." His main purpose in visiting Paris was to superintend the transcription of the correspondence of Barillon, which he needed for his proposed life of James II. The book was never finished, but the fragment he completed was published in 1808, and was translated into French by Armand Carrel in 1816. Fox was not favourably impressed by Napoleon. He saw a good deal of French society, and was himself much admired for his hearty defence of his rival Pitt against a foolish charge of encouraging plots for Napoleon's assassination. On his return he resumed his regular attendance in the House of Commons. The history of the renewal of the war, of the fall of Addington's ministry, and of the formation of Pitt's second administration is so fully dealt with in the article on Pitt (p. c.) that no more need be said here.

The death of Pitt left Fox so manifestly the foremost man in public life that the king could no longer hope to exclude him from office. The formation of a ministry was entrusted by the king to Lord Grenville, but when he named Fox as his proposed secretary of state for foreign affairs George III. accepted him without demur. Indeed his hostility seems to a large extent to have died out. A long period of office might now have appeared to lie before Fox, but his health was undermined. Had he lived it may be considered as certain that the war with Napoleon would have been conducted with a vigour which was much wanting during the next few years. In domestic politics Fox had no time to do more than insist on the abolition of the slave trade. He, like Pitt, was compelled to bow to the king's invincible determination not to allow the emancipation of the Roman Catholics. When a French adventurer calling himself Guillet de la Gervillière, whom Fox at first "did the honour to take for a spy," came to him with a scheme for the murder of Napoleon, he sent a warning on the 20th of February to Talleyrand. The incident gave him an opportunity for reopening negotiations for peace. A correspondence ensued, and British envoys were sent to Paris. But Fox was soon convinced that the French ministers were playing a false game. He was resolved not to treat apart from Russia, then the ally of Great Britain,
FOX, E.—FOX, G.

765

to consent to the surrender of Sicily, which Napoleon insisted upon, unless full compensation could be obtained for King Ferdinand of the Two Sicilies. The negotiations were not directed by Fox, but by colleagues who took over his work at the foreign office when his health began to fail in the summer of 1826. He showed symptoms of dropsy, and operations only procured him temporary relief. After carrying his motion for the abolition of the slave trade on the 15th of June, he was forced to give up attendance in parliament, and he died in the house of the duke of Devonshire, at Chiswick, on the 13th of September 1826. His wife survived him till the 8th of July 1842. No children were born of the marriage. Fox is buried in Westminster Abbey and in the school in which he taught.

The striking personal appearance of Fox has been rendered very familiar by portraits and by innumerable caricatures. The latter were no doubt deliberately exaggerated, and yet a comparison between the head of Fox in Sayer’s plate “Carlo Khan’s triumphal entry into Leadenhall,” and in Abbott’s portrait, shows that the caricaturist did not depart from the original. Fox was twice painted by Sir Joshua Reynolds, once when young in a group with Lady Sarah Bunbury and Lady Susan Strangeways, and once at full length. A half-length portrait by the German painter, Karl Antonio Belke, is in the National Portrait Gallery, which contains also a terra-cotta bust by Nollekens.

AUTHORITIES.—The materials for a life of Fox were first collected by his nephew, Lord Holland, and were then revised and rearranged by Mr Allen and Lord John Russell. These materials appear as Appendix to the Life of C. J. Fox, by C. J. Fox, 1829, and in them Lord John Russell based his Life and Times of C. J. Fox (London, 1859-1866); Sir G. O. Trevelyan’s Early History of C. J. Fox (London, 1880) brings new evidence; Charles James Fox, a Political Study, by J. L. Le B. Hammond (London, 1903), is a series of studies written by an extreme admirer. His Speeches were collected and published in 1815. The newspaper articles (e.g. in The Times) published on the occasion of the centenary of his death contain interesting appreciations. See also Lloyd Sanderson’s The Holland House Circle (1908).

FOX, EDWARD (c. 1496-1538), bishop of Hereford, was born about 1496 at Dursley in Gloucestershire; he is said on very doubtful authority to have been related to Richard Fox (q.v.). From Eton he proceeded to King’s College, Cambridge, and after graduating was made secretary to Wolsey. In 1528 he was sent with Gardiner to Rome to obtain from Clement VII a decretal commission for the trial and decision of the case between Henry VIII and Catherine of Aragon. On his return he was elected provost of Magdalen College, and in 1530 was one of the four conveying to the king Cranmer’s historic advice that he should apply to the universities of Europe rather than to the pope. This introduction led eventually to Cranmer’s promotion over Fox’s head to the archbishopric of Canterbury. After a brief mission to Paris in October 1529, Fox in January 1530 befriended Latimer at Cambridge and took an active part in persuading that university and Oxford to decide in the king’s favour. He was sent to employ similar methods of persuasion at the French universities in 1530-1531, and was also engaged in negotiating a closer league between England and France. In April 1533 he was procurator of convocation when it decided against the validity of Henry’s marriage with Catherine, and in 1534 published his treatise De vera differentia regiae potestatis et ecclesiae (second ed. 1538, English transl. 1548). Various ecclesiastical preferments were now granted him, including the archdeaconry of Leicester (1531) and the bishopric of Hereford (1533). In 1535-1536 he was sent to Germany to discuss the basis of a political and theologica understanding with the Lutheran princes and divines, and had several interviews with Luther, who could not be persuaded, though he was not against the divorce of Henry VIII’s divorces. The principal result of the mission was the Wittenberg articles of 1536, which had no slight influence on the English Ten Articles of the same year. Bucer dedicated to him in 1536 his Commentaries on the Gospels, and Fox’s Protestantism was also illustrated by his patronage of Alexander Ales, whom he defended before Convocation. Fox is credited with the authorship of several proverbial sayings, such as “the surest way to peace is a constant preparedness for war” and “time and I will challenge any two in the world.” The former at any rate is only a variation of the Latin si vis pacem, para bellum, and probably the latter is not more original in Fox than in Philip II., to whom it is usually ascribed. Fox died on the 8th of May, 1538 and was buried in the church of St Mary Mountaw, London. His chief distinction is perhaps that he was the most Lutheran of Henry VIII’s bishops, and was largely responsible for the Ten Articles of 1536.

FOX, GEORGE (1624-1661), the founder of the “Society of Friends” or “Quakers,” was born at Drayton, Leicestershire, in July 1624. His father, Christopher Fox, called by the neighbours “the greatest mischievous waster by occupation; and his mother, Mary Lago, “an upright woman and accomplished above most of her degree,” was “of the stock of the martyrs.” George from his childhood “appeared of another frame than the rest of his brethren, being more religious, inward, still, solid and observing beyond his years”; and he himself declares: “When I came to eleven years of age I knew pureress and righteousness; for while a child I was taught how to walk to be kept pure.” Some of his relations wished that he should be educated for the ministry; but his father apprenticed him to a shoemaker, who also dealt in leather and cattle. In this service he remained till the nineteenth year. According to Penn, he “took most delight in sheep,” but he himself simply says: “A good deal went through my hands. . . . People had generally a love to me for my innocence and honesty.” In 1643, being upon business at a fair, and having accompanied some friends to the village public-house, he was troubled by a proposal to “drink healths,” and withdrew in grief of spirit. “When I had done what business I had to do I returned home, but did not go to bed that night, nor could I sleep, but sometimes walked in and out, and sometimes prayed and cried to the Lord, who said unto me, ‘Thou seest all the earth is full of vanity and old people into the earth; thou must forsake all, both young and old, and keep out of all, and be a stranger unto all.’ Then, at the command of God, on the ninth day of the seventh month, 1643, I left my relations and broke off all familiarity or fellowship with old or young.”

Thus briefly he describes what appears to have been the greatest moral crisis in his life. The four years which followed were a time of great perplexity and distress, though sometimes Penn himself, and sometimes his friends or acquaintances, brought him into such a heavenly joy that I thought I had been in Abraham’s bosom.” He would go from town to town, “travelling up and down as a stranger in the earth, which way the Lord inclined my heart; taking a chamber to myself in the town where I came, and tarrying sometimes a month, more or less, in a place”; and the reason he gives for this migratory habit is that he was “afraid both of professor and profane, lest, being a tender young man, he should be hurt by conversing much with either.” The same fear often led him to shun all society for days at a time; but frequently he would apply to “professors” for spiritual direction and consolation. These applications, however, never proved successful; he invariably found that his advisers “possessed not what they professed.” Some recommended marriage, others enlistment as a soldier in the civil wars; one “ancient priest” bade him take tobacco and sing psalms; another of the same fraternity, “in high account,” advised physic and blood-letting.

About the beginning of 1646 his thoughts began to take more definite shape. “One day, approaching Coventry, the Lord walked with me, and told me, before I was born of God and had passed from death unto life; and that was soon followed by other ‘openings’ to the effect that ‘being bated at Oxford or Cambridge was not enough to fit and qualify men to be ministers of Christ,’” and that God who made the world did not dwell in temples made with hands.” He also experienced deeper manifestations of Christ within his own soul. “When I myself was in the deep, shut up under all [the burden of corruptions], I could not believe that I should ever
overcome; my troubles, my sorrows and my temptations were so great that I thought many times I should have despair, I was so tempted. But when Christ opened to me how He was tempted by the same devil, and overcame him and bruised his head, and that through Him, and His power, light, grace and spirit, I should overcome also, I had confidence in Him; so He it was that opened to me, when I was shut up and had no hope nor faith. Christ, who had enlightened me, gave me His light to believe in; He gave me hope which He himself revealed in me; and He gave me His and His spirit also, which I found sufficient in the deeps and in weaknes.

In 1647 he records that at a time when all outward help had failed "I heard a voice which said, 'There is one, even Christ Jesus, that can speak to thy condition.' And when I heard it my heart did leap for joy." In the same year he first openly declared his message in the neighbourhood of Dukinfield and Manchester (see Friends, Society of).

In 1649, as he was walking towards Nottingham, he heard the bell of the "steeple house" of the city, and was admonished by an inward voice to go forward and cry against the great idol and the worshippers in it. Entering the church he found the preacher engaged in expounding the words, "We have also a more sure word of prophecy," from which the ordinary Protestant doctrine of the supreme authority of Scripture was being enforced in a manner which appeared to Fox so defective or erroneous as to call for his immediate and most energetic protest. Lifting up his voice against the preacher's doctrine, he declared that it is not by the Scripture alone, but by the divine light that the Scripture were given. That doctrines ought to be judged. He was carried off to prison, where he was detained for some time, and from which he was released only by the favour of the sheriff, whose sympathies he had succeeded in enlist ing.

In 1650 he was imprisoned for about a year at Derby on a charge of blasphemy. On his release, overwrought and weakened by six months spent "in the common gaol and dungeon," he performed what was almost the only and certainly the most pronounced act of his life which had the appearance of wild fanaticism. Through the streets of Lichfield, on market day, he walked barefoot, crying, "Woe to the bloody city of Lichfield." His own explanation of the act, connecting it with the martyrdom of a thousand Christians in the time of Diocletian, is not convincing. His proceeding was probably due to a horror of the city arising from a subconscious memory of what he must have heard in childhood from his mother ("of the stock of the martyrs") concerning a martyr, a woman, burnt in the reign of Mary at Lichfield, who had been taken thither from Manchester, a village two miles from his home in which he had worked as a journeyman shoemaker (see The Journeys of John Fox, by W. R. L. Euens, and The Reformation, by the Rev. B. Richings). He must also have heard of the burning of Edward Wightman in the same city in 1612, the last person burned for heresy in England.

It would be here out of place to follow with any minuteness the details of his subsequent imprisonments, such as that at Carlisle in 1653; London 1654; Launceton 1656; Lancaster 1660, and again in 1663, whence he was taken to Scarborough in 1665; and Worcester 1673. During these terms of imprisonment his pen was not idle, as appears above, as by numerous letters, pastoral and exhortations which have been preserved; while during his intervals of liberty he was unwearyed in the work of "declaring truth" in all parts of the country. In 1669 he married Margaret, widow of Judge Fell, of Swarthmoor, near Ulverston, who, with her family, had been among his earliest converts. In 1671 he visited Barbados, Jamaica, and the American continent, and shortly after his return in 1673 he was, as has been already noted, apprehended in Worcester-shire for attending meetings which were forbidden by the law.

At Worcester he suffered a captivity of nearly fourteen months. In 1677 he visited Holland along with Barclay, Penn and seven others; and this visit he repeated (with five others) in 1684. The later years of his life were spent mostly in London, where he continued to speak in public, comparatively unmolested, until within a few days of his death, which took place on the 13th of January 1691 (1690 o.s.).

William Penn has left on record an account of Fox from personal knowledge—a Brief Account of the Rise and Progress of the People called Quakers, written as a preface to Fox's Journal. Although a man of large size and great bodily strength, he was "very temperate, eating little and sleeping less." He was a man of strong personality, of measured utterance, "civil" (says Penn) "beyond all forms of breeding." From his Journal we gather that he had piercing eyes and a very loud voice, and wore good clothes. Unlike the Roundheads, he wore his hair long. Even before his marriage with Margaret Fell he seems to have been fairly well off; he does not appear to have worked for a living after he was nineteen, and yet he had a horse, and speaks of having money to give to those who were in need. He had much practical common-sense, and keen sympathy for all who were in distress and for animals. The mere fact that he was able to attract to himself so considerable a body of respectable followers, including such men as Ellwood, Barclay, Pennington and Penn, is sufficient to prove that he possessed in a very eminent degree the power of conviction, persuasion, and moral ascendency; while of his personal uprightness, single-mindedness and sincerity there can be no question.

The writings of Fox are enumerated in Joseph Smith's Catalogue of Books, The Enquirer, The Friend. James Mackintosh has said that "it is one of the most extraordinary and instructive narratives in the world, which no reader of competent judgment can peruse without revering the virtue of the writer." The First Part of his Journal was originally published in London, 1691, and an edition known as the Bicentenary Edition, with notes biographical and historical (reprint of 1901 or later), will be found the most useful of the imitations. An exact transcript of the Journal has also been issued by the Cambridge University Press. A Life of George Fox, by Dr Thomas Hodgkin; The Fellows of Swarthmoor Hall, by Maria Webb; and The Life and Character of George Fox, by John Stephenson Rowntree, are valuable. For a mention of other works, and an account of the principles and history of the Society of Friends, see together with other similar information about Fox, see the article Friends, Society of.

(AN. B.)

FOX, RICHARD (c. 1448–1539), successively bishop of Exeter, Bath and Wells, Durham, and Winchester, lord privy seal, and founder of Corpus Christi College, Oxford, was born about 1448 at Ropesley near Grantham, Lincolnshire. His parents belonged to the yeoman class, and there is some obscurity about Fox's early career. It is not known at what school he was educated, nor at what college, though the presumption is in favour of Magdalen, Oxford, whence he drew so many members of his subsequent foundation, Corpus Christi. He also appears to have studied at Cambridge, but nothing definite is known of the first thirty-five years of his career. In 1484 he was in Paris, and was licensed for an ex cathedra judgment (see The Ministry of John Colet, and the English Church in the Reign of Henry VIII, by E. F. J. Carpenter, and Henry VII, by J. H. Round). He rendered himself obnoxious to Richard III. is a matter of speculation. At any rate he was brought into contact with the earl of Richmond, who was then beginning his quest for the English throne, and was taken into his service. In January 1483 Richard intervened to prevent Fox's appointment to the vicarage of Stepney on the ground that he was keeping company with the "great rebel, Henry ap Tudor."

The important offices conferred on Fox immediately after the battle of Bosworth imply that he had already seen more of power than his republican sympathizers were to be traced in records. Doubtless Henry VII. had every reason to reward his companions in exile, and to rule like Ferdinand of Aragon by means of lawyers and churchmen rather than trust nobles like those who had made the Wars of the Roses. But without an intimate knowledge of Fox's political experience and capacity he would hardly have made him his principal secretary, and soon afterwards lord privy seal and bishop of Exeter (1487). The ecclesiastical preference was merely intended to provide a salary not at Henry's expense; for Fox never saw either Exeter or the diocese of Bath and Wells to which he was translated in 1492. His activity was confined to political and especially diplomatic channels; so long as Morton lived, Fox was his subordinate, but after the archbishop's death he was second to none in Henry's confidence, and he had an important share in all the diplomatic
work of the reign. In 1487 he negotiated a treaty with James III. of Scotland, in 1491 he baptized the future Henry VIII., in 1492 he helped to conclude the treaty of Etaples, and in 1497 he was chief commissioner in the negotiations for the famous commercial agreement with the Netherlands which Bacon seems to have been the first to call the Magna Intercessus.

Meanwhile in 1494 Fox had been translated to Durham, not merely because it was a richer see than Bath and Wells but because of its political importance as a palatine earldom and its position with regard to the Borders and relations with Scotland. For these reasons rather than from any ecclesiastical scruples Fox visited and resided in his new diocese; and he occupied Norham Castle, which he fortified and defended against a Scottish raid in Perkin Warbeck’s interests (1497). But his energies were principally devoted to pacific purposes. In that same year he negotiated Perkin’s retirement from the court of James IV., and in 1498–1499 he completed the negotiations for that treaty of marriage between the Scottish king and Henry’s daughter Margaret which led ultimately to the union of the two crowns in 1603 and of the two kingdoms in 1707. The marriage itself did not take place until 1503, just a century before the accession of James I.

This consummated Fox’s work in the north, and in 1501 he was once more translated to Winchester, then reputed the richest bishopric in England. That year he also concluded a conclusion of marriage negotiations not less momentous in their ultimate results, when Prince Arthur was betrothed to Catherine of Aragon. His last diplomatic achievement in the reign of Henry VII. was the betrothal of the king’s younger daughter Mary to the future emperor Charles V. In 1500 he was elected chancellor of Cambridge University, an office not confined to noble lords until a much more democratic age, and in 1507 master of Pembroke Hall in the same university. The Lady Margaret Beaufort made him one of her executors, and in this capacity as well as in that of chancellor, he had the chance of exerting his influence for the benefit of St. John’s College and the Lady Margaret professorships and readerships. His financial work brought him a less enviable notoriety, though a curious freak of history has deprived him of the credit which is his due for “Morton’s fork.” The invention of that ingenious dilemma for extorting contributions from poor and rich alike is ascribed as a tradition to Morton by Bacon; but the story is told in greater detail of Fox by Erasmus, who says he had it from Sir Thomas More, a well-informed contemporary authority. It is in keeping with the somewhat malicious saying about Fox reported by Tyndale that he would make his father say his king, which after all is not so damning as Wolsey’s dying words.

The accession of Henry VIII. made no immediate difference to Fox’s position. If anything, the substitution of the careless pleasure-loving youth for Henry VII. increased the power of his ministry, the personnel of which remained unaltered. The Venetian ambassador calls Fox “alter rex” and the Spanish ambassador Carroz says that Henry VIII. trusted him more than any other adviser, although he also reports Henry’s warning that the bishop of Winchester was, as his name implied, a “fox indeed.” He was the chief of the ecclesiastical statesmen who belonged to the school of Morton, believed in frequent parliaments, and opposed the spirited foreign policy which laymen like Surrey are supposed to have advocated. His colleagues were Warham and Ruthal, but Warham and Fox differed on the question of Henry’s marriage, Fox advising the completion of the match with Catherine while Warham expressed doubts as to its canonical validity. They also differed over the prerogatives of Canterbury with regard to probate and other questions of ecclesiastical jurisdiction.

Wolsey’s rapid rise in 1511 put an end to Fox’s influence. The pacific policy of the first two years of Henry VIII.’s reign was succeeded by an adventurous foreign policy directed mainly against France; and Fox complained that no one durst do anything in opposition to Wolsey’s wishes. Gradually Warham and Fox retired from the government; the occasion of Fox’s resignation of the privy seal was Wolsey’s ill-advised attempt to drive Francis I. out of Milan by financing an expedition led by the emperor Maximilian in 1516. Tunstall protested, Wolsey took Warham’s place as chancellor, and Fox was succeeded by Rathal, who, said the Venetian ambassador, “sang treble to Wolsey’s bass.” He bore Wolsey no ill-will, and warmly congratulated him two years later when warlike adventures were abandoned at the peace of London. But in 1522 when war was again declared he emphatically refused to bear any part of the responsibility, and in 1523 he opposed in convocation the financial demands which met with a more strenuous resistance in the House of Commons.

He now devoted himself assiduously to his long-neglected episcopal duties. He expressed himself as being as anxious for the reformation of the clergy as Simon for the coming of the Messiah; but while he welcomed Wolsey’s never-realized promises, he was too old to accomplish much himself in the way of remedying the clerical and especially the monastic depravity, licence and corruption he deplored. His sight failed during the last ten years of his life, and there is no reason to doubt Matthew Parker’s story that Wolsey suggested his retirement from his bishopric on a pension. Fox replied with some warmth, and Wolsey had to wait until Fox’s death before he could add Winchester to his archbishopric of York and his abbey of St. Alban’s. His son, the bishop of Exeter, was the illegitimate son on whom (aged 18) he had already conferred a deanship, four archdeaconries, five prebends and a chancellorship.

The crown of Fox’s career was his foundation of Corpus Christi College, which he established in 1515–1516. Originally he intended it as an Oxford house for the monks of St. Swithin’s, Winchester; but he is said to have been dissuaded by Bishop Oldham, who denounced the monks and foretold their fall. The scheme adopted breathed the spirit of the Renaissance; provision was made for the teaching of Greek, Erasmus lauded the institution’s male purpose of excluding girls. If the results were not always as the ruler of the college, William Vives, had brought from Italy to teach Latin, and the reader in theology was instructed to follow the Greek and Latin Fathers rather than the scholastic commentators. Fox also built and endowed schools at Taunton and Grantham, and was a benefactor to numerous other institutions. He died at Wolvesey on the 6th of October 1528; Corpus possesses several portraits and other relics of its founder.

FOX, ROBERT WERE (1789–1877), English geologist and natural philosopher, was born at Falmouth on the 26th of April 1789. He was a member of the Society of Friends, and was descended from members who had long settled in Cornwall, although he was not related to George Fox who had introduced the community into the county. He was distinguished for his researches on the internal temperature of the earth, being the first to prove that the heat increased definitely with the depth; his observations being conducted in Cornish mines from 1815 for a period of forty years. In 1829 he commenced a series of experiments on the artificial production of miniature metalliferous veins by means of the long-continued influence of electric currents, and his main results were published in Observations on Mineral Veins (Rep. Royal Cornwall Polytech. Soc., 1836). He was one of the founders in 1833 of the Royal Cornwall Polytechnic Society. He constructed in 1834 an improved form of deflector dipping needle. In 1848 he was elected F.R.S. His garden at Penjerrick near Falmouth became noted for the number of exotic plants which he had naturalized. He died on the 25th of July 1877. (See A Catalogue of the Works of Robert Were Fox, F.R.S., with a Sketch of his Life, by J. H. Collins, 1878.)

His daughter, Caroline Fox (1810–1871), born at Falmouth on the 24th of May 1819, is well known as the authoress of A
diary, recording memories of many distinguished people, such as John Stuart Mill, John Sterling and Carlyle. Selections from her diary and correspondence (1835–1871) were published under the title of Memories of Old Friends (ed. by H. N. Pym, 1881; 2nd ed., 1882). She died on the 12th of January 1871.

FOX, SIR STEPHEN (1677–1716), English statesman, born on the 27th of March 1677, was the son of William Fox, of Farley, in Wiltshire, a yeoman farmer. At the age of fifteen he first obtained a situation in the household of the earl of Northumberland; then he entered the service of Lord Percy, the earl's brother, and was present with the royalist army at the battle of Worcester as Lord Percy's deputy at the ordnance board. Accompanying Charles II. in his flight to the continent, he was appointed manager of the royal household, on Clarendon's recommendation as "a young man bred under the severe discipline of Lord Percy ... very well qualified with languages, and all other parts of clerkship, honesty and discretion."

The skill with which he managed the exiguous finances of the exiled court earned him further confidence and promotion. He was employed on several important missions, and acted eventually as intermediary between the king and General Monk. Honours and emolument were his reward after the Restoration; he was appointed to the lucrative offices of first clerk of the board of green cloth and paymaster-general of the forces. In November 1661 he became member of parliament for Salisbury. In 1665 he was knighted, was returned for Wiltshire and this county, and in 1666 succeeded the earl of Rochester as a commissioner of the treasury, filling that office for twenty-three years and during three reigns. In 1680 he resigned the paymastership and was made first commissioner of horse. In 1684 he became sole commissioner of horse. He was offered a peerage by James II., on condition of turning Roman Catholic, but refused, in spite of which he was allowed to retain his commissions. In 1685 he was again M. P. for Salisbury, and opposed the bill for a standing army supported by the king. During this time he maintained an attitude of decent reserve, but on James's flight, submitted to William III., who confirmed him in his offices. He was again elected for Westminster in 1691 and 1695, for Cricklade in 1698, and finally in 1713 once more for Salisbury. He died on the 28th of October 1716. It is his distinction to have founded Chelsea hospital, and to have contributed £1,500 in aid of this laudable public work. Though his place as a statesman is in the second or even the third rank, yet he was a useful man in his generation, and a public servant who creditably discharged all the duties with which he was entrusted. Unlike other statesmen of his day, he grew rich in the service of the nation without being suspected of corruption, and without forfeiting the esteem of his contemporaries.

He was twice married (1651 and 1703); by his first wife, Elizabeth Whittle, he had seven sons, who predeceased him, and three daughters; by his second, Christian Hopes, he had two sons and two daughters. The elder son by the second marriage, Stephen (1704–1710), was created Lord Ilchester and Stavordale in 1747 and earl of Ilchester in 1756. In 1756 he took the additional name of Strangways, and his descent, the family of Fox-Strangways, still hold the earldom of Ilchester. The younger son, Henry, became the 1st Lord Holland (q.v.).

FOX, SIR WILLIAM (1812–1893), New Zealand statesman, third son of George Townshend Fox, deputy-lieutenant for Durham county, was born in England on the 9th of June 1812, and educated at Wadham College, Oxford, where he took his degree in 1832. Called to the bar in 1842, he emigrated immediately to New Zealand, where, on the death of Captain Arthur Wakefield, killed in the Wairau Hill fight, he became the New Zealand Company's agent for the South Island. While holding this position he made a memorable exploring march on foot from Nelson to Canterbury, through Cannibal Gorge, in the course of which he discovered the fertile pastoral country of Amuri. In 1848 Governor Grey made Fox attorney-general, but he gave up the post almost at once in order to join the agitation, then at its height, for a free constitu-

As the political agent of the Wellington settlers he sailed to London in 1850 to urge their demands in Downing Street. The colonial office, however, refused to recognize him, and, after publishing a sketch of the New Zealand settlements, The Six Colonies of New Zealand, and travelling in the United States, he returned to New Zealand and again threw himself with energy into public affairs. When government by responsible ministers was at last initiated, in 1856, Fox ousted the first ministry and formed a cabinet, only to be himself beaten in turn after holding office but thirteen days. In 1861 he regained office, and was somewhat more fortunate, for he remained premier for nearly thirteen months. Again, in the latter part of 1863 he took office: this time with Sir Frederick Whitaker as premier, an arrangement which endured for another thirteen months. Fox's third premiership began in 1869 and lasted until 1872. His fourth, which was a matter of temporary convenience to his party, lasted only five weeks in March and April 1873. Soon afterwards he left politics, and, though he reappeared after some years and led the attack which overthrew Sir George Grey's ministry in 1879, he lost his seat in the dissolution which followed in that year and did not again enter parliament. He was made K.C.M.G. in 1886. For the thirty years between 1850 and 1880 Sir William Fox was one of the half-dozen most notable public men in the colony. Impulsive and controversial, a fluent and rousing speaker, and a ready writer, his warm and sympathetic nature made him a good contrast to the more masculine type of colonists. Though he was in the first ten years to be the most dangerous leader of the Opposition in the colony's parliament, though as premier he was at a disadvantage when measured against more patient and more astute party managers. His activities were first devoted to secure self-government for the New Zealand colonists. Afterwards his sympathies made him prominent among the champions of the Maori race, and he laboured indefatigably for their rights and to secure permanent peace with the tribes and a just settlement of their claims. It was during his third premiership that this William Grey was a man of his word. He had long denounced the disloyal and disaffected for their influence and skill of Sir Donald M'Lean, native minister in the Fox cabinet. Finally, after Fox had left parliament he devoted himself, as joint-commissioner with Sir Francis Dillon Bell, to the adjustment of the native land-claims on the west coast of the North Island. The able reports of the commissioners were his last public service, and the carrying out of their recommendations gradually removed the last serious native trouble in New Zealand. When, however, in the course of the native wars from 1860 to 1870 the colonists of New Zealand were exposed to cruel and unjust imputations in England, Fox zealously defended them in a book, The War in New Zealand (1860), which was not only a spirited vindication of his fellow-settlers, but a scathing criticism of the generalship of the officers commanding the imperial troops in New Zealand. Throughout his life Fox was a consistent advocate of total abstinence. It was he who founded the New Zealand Alliance, and he undoubtedly aided the growth of the prohibition movement afterwards so strong in the colony. He died on the 23rd of June 1863, exactly twelve months after his wife, Sarah, daughter of William Gilcombie. (W. P. R.)

FOX, a name (female, "vixen") properly applicable to the single wild British representative of the family Canidae (see CARNIVORA), but in a wider sense used to denote fox-like species from all parts of the world, inclusive of many from South America which do not really belong to the same group. The fox was included by Linnaeus in the same genus with the dog and the wolf, under the name of Canis vulpes, but at the present day is regarded by most naturalists as the type of a separate genus, and should then be known as Vulpes alpeces or Vulpes vulpes. From 1

1The word is common to the Teutonic languages, e.g. Dutch vos, Ger. Fuchs; the ultimate origin is unknown, but a connection has been suggested with Sanskrit puccha, tail. The feminine "vixen" represents the O. Eng. fynxen, due to the change from to y and addition of the femininitimation-en, cf. O. Eng. gyden, goddess, and Latin Fata, the Roman goddess. (See fuchs, vixen, cf. fox in the entry for English pronunciation; sex, for fox, is found in the Ancor Rites, c. 1230.)
At a gestation of from 60 to 65 days, the vixen during the month of April gives birth to cubs, of which from five to eight usually go to form a litter. When first born these are clothed with a uniform slaty-grey fur, which in due course gives place to a coat of more tawny hue than the adult livery. In a year and a half the cubs attain their full development; and from observations on captive specimens it appears that the duration of life ought to extend to some thirteen or fourteen years. In the care and defence of her young the vixen displays extraordinary solicitude; and boldness is shown in her bearing, when occasion demands, her accustomed timidity and caution. Like most other young animals, fox-cubs are exceedingly playful, and may be seen chasing one another in front of the mouth of the burrow, or even running after their own tails.

Young foxes can be tamed to a certain extent, and do not then emit the well-known odour to any great degree unless excited. The species cannot, however, be completely domesticated, and never displays the affectionate traits of the dog. It was long believed that foxes and dogs would never interbreed; but several instances of such unions have been recorded, although they are undoubtedly rare. When suddenly confronted in a situation where immediate escape is impossible, the fox, like the wolf, will not hesitate to resort to the death-feigning instinct. Smartness in avoiding traps is one of the most distinctive traits in the character of the species; but when a trap has once claimed its victim, and is consequently no longer dangerous, the fox is always ready to take advantage of the gratuitous meal.

Red fox-skins are largely imported into Europe for various purposes, the American imports alone formerly reaching as many as 60,000 skins annually. Silver fox is one of the most valuable of all, and has also having been given for an unusually fine pair of skins in 1902.

Of foxes certainly distinct specifically from the typical representative of the group, one of the best known is the Indian *Vulpes bengalensis*, a species much inferior in point of size to its European relative, and lacking the strong odour of the latter, from which it is also distinguished by the black tip to the tail and the pale-coloured backs of the ears. The corsac fox (*V. corsac*), ranging from southern Russia and the Caspian provinces across Asia to Amurland, may be regarded as a northern representative of the Indian species; while the pale fox (*V. pallidus*), of the Suakin and Dongola deserts, may be regarded as the African representative of the group. Possibly the kit-fox (*V. velox*), which has likewise a black tail-tip and pale ears, may be the North American form of the same group. The northern fennec (*V. famelicus*), whose range extends apparently from Egypt and Somaliland through Palestine and Persia into Afghanistan, seems to form a connecting link between the two more typical foxes and the small African species properly known as fenneces. The long and bushy tail in the northern species has a white tip and a dark gland-patch near the root, but the backs of the ears are fawn-coloured. The enormous length of the ears and the small bodily size (inferior to that of any other member of the family) suffice to distinguish the true fennec (*V. zerda*) of Algeria and Egypt, in which the general colour is pale and the tip of the relatively short tail black. South of the Zambezi the group reappears in the shape of the asse-fox or fennec. (*V. cama*), a dark-coloured species, with a black tip to the long, bushy tail and reddish-brown ears.

Passing from South Africa to the north polar regions of both the Old and the New World, inclusive of Iceland, we enter the domain of the Arctic fox (*Alopex lagopus*), a very distinct species characterized by the hairy soles of its feet, the short, blunt ears, the long, bushy tail, and the great length of the fur in winter. The upper parts in summer are usually brownish and the under parts white; but in winter the whole coat, in this phase of the species, turns white. In a second phase of the species, the colour, which often displays a slaty hue (whence the name of blue fox), remains more or less the same throughout the year, the winter coat being, however, recognizable by the great length of the fur. Many at least of the "blue fox" skins of the fur-trade are white skins dyed. About 2000 blue fox-skins were
FOXE, J.

annually imported into London from Alaska some five-and-twenty years ago. Arctic foxes feed largely on sea-birds and lemmings, laying up hidden stores of the last-named rodents for winter use.

The American grey fox, or Virginian fox, is now generally ranged as a distinct genus (or a subgenus of Canis) under the name of *Viker caninae-argentarius*, on account of being distinguished, as already mentioned, by the presence of a ridge of long erectile hairs along the upper surface of the tail and of a projection to the postero-inferior angle of the lower jaw. The prevailing colour of the fur of the proper parts is iron-grey, the ears having a white edge, and the tail is grey, being marked with a black band. The so-called foxes of South America, such as the crab-eating fox (*C. thous*), Azara's fox (*C. azarae*), and the colepeo (*C. magellanicus*), are aberrant members of the typical genus Canis. On the other hand, the long-eared fox or Delalande's fox (*Otocyon megalotis*) of south and east Africa represents a totally distinct genus.

FOXE, JOHN (1516-1557), the author of the famous *Book of Martyrs*, was born at Boston, in Lincolnshire, in 1516. At the age of sixteen he is said to have entered Brasenose College, Oxford, where he was the pupil of John Harding or Hawarden, and had for room-mate Alexander Nowell, afterwards dean of St. Paul's. His authenticated connexion at the university is, however, with Magdalen College. He took his B.A. degree in 1537 and his M.A. in 1543. He was lecturer in logic in 1540-1541. He wrote several Latin plays on scriptural subjects, of which the best, *De Christo triumphans*, was repeatedly printed, (London, 1551; Basel, 1556, &c.), and was translated into English by Richard Day, son of the printer. He became a fellow of Magdalen College in 1539, resigning in 1545. It is said that he refused to conform to the rules for regular attendance at chapel, and that he protested both against the enforced celibacy of fellows and the obligation to take holy orders within seven years of their election. The customary statement that he was expelled from his fellowship is based on the untrustworthy biography attributed to his son Samuel Foxe, but the college records state that he resigned of his own accord and ex honesta causa. The letter in which he protests to President Ogilthorpe against the charges of irreverence, &c., brought against him is printed in Pratt's edition (vol. i. Appendix, pp. 58-61).

On leaving Oxford he acted as tutor for a short time in the house of the Lucy's of Charlecote, near Stratford-on-Avon, where he married Agnes Randall. Late in 1547 or early in the next year he went to London. He found a patron in Mary Fitzroy, duchess of Richmond, and having been ordained "deacon" by Ridley in 1550, he settled at Reigate Castle, where he acted as tutor to the duchess's nephews, the orphan children of Henry Howard, earl of Surrey. On the accession of Queen Mary, Foxe was deprived of his tutorship by the boy's grandfather, the duke of Norfolk, who was now released from prison. He retired to Strasbourg, and occupied himself with a Latin history of the Christian persecutions which he had begun at the suggestion of Lady Jane Grey. He had assistance from two clerics of widely differing opinions—from Edmund Grindal, who was later, as archbishop of Canterbury, to maintain his puritan convictions in opposition to Elizabeth; and from John Aylmer, afterwards one of the bitterest opponents of the Puritan party. This book, dealing chiefly with Wycliffe and Huss, and coming down to 1500, formed the first outline of the *Acts and Monuments*. It was printed by Wendelin Richelius with the title of *Commentariorum rerum in ecclesia gestarum* (Strassburg, 1554). In the year of its publication Foxe removed to Frankfurt, where he found the English colony of Protestant refugees divided into two camps. He made a vain attempt to frame a compromise which should be acceptable to the extreme Calvinists and by the partisans of the Anglican doctrine. He removed (1555) to Brussels, where he worked as printer's reader to Johann Herbst or Oporinus. He made steady progress with his great book as he received reports from England of the religious persecutions there, and he issued from the press of Oporinus his pamphlet, *Ad incolas ac praecipuas Angliae proceres supplicatio* (1557), a plea for toleration addressed to the English nobility. In 1559 he completed the Latin edition of his *Martyrology* and returned to England. He lived for some time at Aldgate, London, in the house of his former pupil, Thomas Howard, now duke of Norfolk, who retained a sincere regard for his tutor and left him a small pension in his will. He became associated with John Day the printer, himself once a Protestant exile. Foxe was ordained to the see of Edmund Grindal, bishop of London, in 1560, and besides much literary work he occasionally preached at Paul's Cross and other places. His work had rendered great service to the government, and he might have had high preferment in the Church but for the Puritan views which he consistently maintained. He held, however, the prebend of Shipton in Salisbury cathedral, and is said to have been for a short time rector of Cripplegate.

In 1563 he was issued from the press of John Day the first English edition of the *Acts and Monuments*. It was intensified and described the great persecution and horrible troubles that have been wrought, and practised by the Remises Prelates, specially in this Realm of England and Scotland, from the year of our Lorde a thousand to the time now present. Gathered and collected according to the true copies and Writings certificatory as well of the parties themselves that suffered, as also out of the Bishop's Registers, which were the doors thereof, by John Foxe, commonly known as the *Book of Martyrs*. Several gross errors which had appeared in the Latin version and had been since exposed, were corrected in this edition. Its popularity was immense and signal. The Marian persecution was still fresh in men's minds, and the graphic narrative intensified in its numerous readers the fierce hatred of Spain and of the Inquisition which was one of the master passions of the reign. Nor was its influence transient. For generations the popular conception of Roman Catholicism was derived from its bitter pages. Its accuracy was immediately attacked by Catholic writers, notably in the *Dialogi sex* (1566), nominally from the pen of Alan Cope, but in reality by Nicholas Harpsfield and by Robert Parsons in *Three Conversions of England* (1570). These criticisms induced Foxe to produce a second corrected edition, *Ecclesiastical History*, containing the *Acts and Monuments of things passed in every kynges tyme* in 1570, a copy of which was ordered by Convocation to be placed in every collegiate church. Foxe based his accounts of the martyrs partly on authentic documents and reports of the trials, and on statements received direct from the friends of the sufferers, but he was too hasty a worker and too violent a partisan to produce anything like a correct or impartial account of the mass of facts with which he had to deal. Anthony a Wood says that Foxe "believed and reported all that was told him, and there is every reason to suppose that he was purposely biased, and continually deceived by those whose interest it was to bring discredit on his work," but he admits that the book is a monument of his industry, his laborious research and his sincere piety. The gross blunders due to carelessness have often been exposed, and there is no doubt that Foxe was only too ready to believe evil of the Catholics, and he cannot always be exonerated from the charge of wilful falsification of evidence. It should, however, be remembered in his honour that his advocacy of religious toleration was far in advance of his day. He pleaded for the despised Dutch Anabaptists, and remonstrated with John Knox on the ruinous of his *First Blast of the Trumpet*. Foxe was one of the earliest students of Anglo-Saxon, and he and Day published an edition of the Saxon gospels under the patronage of Archbishop Parker. He died on the 18th of April 1557 and was buried at St Giles's, Cripplegate.

1 Printed by Oporinus and Nicolaus Blyngere. The title is *Rerum in ecclesia gestarum... pars prima, in qua trium de vitis per Angliam et Scotoiam gentis aitque in primitis de horrendis sub Maria nobis regina persecutione narrativo continuetur,*
FOXGLOVE—FOY

771

A list of his Latin tracts and sermons is given by Wood, and others, some of which were never printed, appear in Balfour. Four editions of the Aetes and Monuments appeared in Foxe’s lifetime. The eighth edition (1641) contains a memoir of Foyle purporting to be by his son Samuel, the MS. of which is in the British Museum (Lansdowne MS. 388). Samuel Foxe’s authorship is disputed, with much show of reason, by Dr S. R. Maitland in On the Memoirs of Foxe ascribed to his Son (1841). The best-known modern edition of the Martyrlogy is that (1837–1841) by the Rev. Stephen R. Cattley, with an introductory life by Canon George Townsend. The numerous inaccuracies of this life and the frequent errors of Foxe’s narrative were exposed by Dr Maitland in a series of tracts (1837–1842), collected (1841–1842) as Notes on the Contributions of the Rev. George Townsend, M.A., . . . to the New Edition of Foxe’s Martyrlogy. The criticism lavished on Cattley and Townsend’s edition led to a new one (1846–1849) under the same editorship. A new text prepared by the Rev. Josiah Pratt was issued (1870) in the “Reformation Series” of the Church Historians of England, with a revised version of Townsend’s Life and appendices giving copies of original documents. Later edition by W. Grinton Berry (1907).

Foyle’s papers are preserved in the Harleian and Lansdowne collections in the British Museum. Extracts from these were edited by J. G. Nichols for the Camden Society (1859). See also W. Winters, Biographical Notes on John Foxe (1876); James Gairdner, History of the English Church in the Sixteenth Century.

FOXGLOVE, a genus of biennial and perennial plants of the natural order Scrophulariaceae. The common or purple foxglove, It flourishes best in siliceous soils, and is not found in the Jura and Swiss Alps. The characters of the plant are as follows: stem erect, roundish, downy, leafy below, and from 18 in. to 5 ft. or more in height; leaves alternate, crenate, rugose, ovate or elliptic, oblong, and of a dull green, with the under surface downy and paler than the upper; radical leaves together with their stalks often a foot in length; root of numerous, slender, whitish fibres; flowers 1½–2½ in. long, pendulous, on one side of the stem, purplish crimson, and hairy and marked with eye-like spots within; segments of calyx ovate, acute, cleft to the base; corolla bell-shaped with a broadly two-lobed obusse mouth, the upper lip entire or obscurely divided; stamens four, two longer than the other two (didymaous); anthers yellow and bilobed; capsule bivalved, ovate and pointed; and seeds numerous, small, oblong, pitted and of a pale brown. As Parkinson remarks of the plant, “It flourith somewhat before Juny, and the seed is ripe in August,” but it may occasionally be found in blossom as late as September. Many varieties of the common foxglove have been raised by cultivation, with flowers varying in colour from white to deep rose and purple; in the variety gloxinioïdes the flowers are almost regular, suggesting those of the cultivated gloxinia. Other species of foxglove with variously coloured flowers have been introduced into Britain from the continent of Europe. The plants may be propagated by unflowered off-sets from the roots, but being biennials are best raised from seed.

The foxglove, probably from folks’glove, that is fairies’ glove, is known by a great variety of popular names in Britain. In the south of Scotland it is called bloody fingers; farther north, dead-men’s-bells; and on the eastern borders, ladies’ thimbles, wild mercury and Scotch mercury. In Ireland it is generally known under the name of fairy thimble. Among its Welsh synonyms are menyg-cllyllon (elven’s gloves), menyg y llbenog (fox’s gloves), byseda cochion (redfingers) and byseda y can (dog’s fingers). In France its designations are gants de notre dame and doigts de la Vierge. The German name Fingerhut (thimble) suggested to Fuchs, in 1543, the employment of the Latin adjective digitalis as a designation for the plant. Other species of foxglove or Digitalis although found in botanical collections are not generally grown. For medicinal uses see Digitalis.

FOX INDIANS, the name, from one of their clans, of an Algonquian tribe, whose former range was central Wisconsin. They call themselves Muskawiuik, “red earth people.” Owing to heavy losses in their wars with the Ojibways and the French, they allied themselves with the Saug tribe about 1750, the two tribes being now practically one.

FOX MORCILLO, SEBASTIAN (1526–1559?), Spanish scholar and philosopher, was born at Seville between 1526 and 1528. About 1548 he studied at Louvain, and, following the example of the Spanish Jew, Judas Abarbanel, published commentaries on Plato and Aristotle in which he endeavoured to reconcile their teaching. In 1559 he was appointed tutor to Don Carlos, son of Philip II, but did not live to take up the duties of the post, as he was lost at sea on his way to Spain. His most original work is the De imitatione, seu de informandis stylis ratione libri II. (1554). He was also the author in his younger days of a tragi-comic dialogue in Latin and Spanish on the education of a son, under the pseudonyms of Gaspar and Francisco Enesius. Among Fox Morcillo’s other publications are: (1) In Topica Ciceronis paraphrases et scholia (1550); (2) In Platonis Timaeum commentarii (1553); (3) Compendium ethicus philosophiae ex Platonico Aristotelico, alisque philosophis collectum; (4) De historiae institutione dialogus (1557), and (5) De naturae philosophia.

He is the subject of an excellent monograph by Urbano Gonzalez de Calle, Sebastian Fox Morcillo: estudio historico-critico de sus obras (Madrid, 1903).

FOY, MAXIMILIEN SÉBASTIEN (1775–1823), French general and statesman, was born at Han in Picardy on the 3rd of February 1775. He was the son of an old soldier who had fought at Fontenoy and had become post-master of the town in which he lived. His father died in 1780, and his early instruction was given by his mother, a woman of English origin and of

Foxglove (Digitalis purpurea), one-third nat. size.

1. Corolla cut open showing the four stamens; rather more than half nat. size.
2. Unripe fruit cut lengthwise.
3. Ripe capsule split open.

D. purpurea, is common in dry hilly pastures and rocky places and by road-sides in various parts of Europe; it ranges in Great Britain from Cornwall and Kent to Orkney, but it does not occur in Shetland or in some of the eastern counties of England.
superior ability. He continued his education at the college of Soissons, and thence passed at the age of fifteen to the artillery school of La Fère. After eighteen months' successful study he entered the army, served his first campaign in Flanders (1790–92), and was present at the battle of Jemmapes. He so attained the rank of captain, and served successfully under Dampierre, Jourdan, Pichegru and Houchard. In 1794, in consequence of having spoken freely against the violence of the extreme party at Paris, he was imprisoned by order of the commissioner of the Convention, Joseph Lebon, at Cambrai, but regained his liberty soon after the fall of Robespierre. He served under Moreau in the campaigns of 1796 and 1797, distinguishing himself in many engagements. The leisure which the treaty of Campo Formio gave him he devoted to the study of public law and modern history, attending the lectures of Christoph Wilhelm von Koch (1737–1813), the famous professor of public law at Strassburg. He was recommended by Desaix to the notice of General Bonaparte, but declined to serve on the staff of the Egyptian expedition. In the campaign in Switzerland (1798) he distinguished himself afresh, though he served only with the general reserve, and he a few years later became a professor of the republican institutions. In Masséna's brilliant campaign of 1799 Foy won the rank of chef de brigade. In the following year he served under Money in the Marengo campaign and afterwards in Tirol.

Foy's republican principles caused him to oppose the gradual rise of Napoleon to the supreme power and at the time of Moreau's trial he escaped arrest only by joining the army in Holland. Foy voted against the establishment of the empire, but the only penalty for his independence was a long delay before attaining the rank of general. In 1806 he married a daughter of General Baraguay d'Hilliers. In the following year he was sent to Constantinople, and there took part in the defence of the Dardanelles against the English fleet. He was next sent to Portugal, and thenceforward he served in the Peninsular War from first to last. Under Junot he won at last his rank of brigadier, and under Soult he held a command in the pursuit of Sir John Moore's army, and under Masséna he fought in the third invasion of Portugal (1810). Masséna reposed the greatest confidence in Foy, and employed him after Busaco in a mission to the emperor. Napoleon now made Foy's acquaintance for the first time, and was so far impressed with his merits as to make him a general of division at once. The part played by General Foy at the battle of Salamanca won him new laurels, but above all he distinguished himself when the disaster of Vittoria had broken the spirit of the army. Foy rose to the occasion; his resistance in the Pyrenees was steady and successful, and only a wound (at first thought mortal) which he received at Orthez prevented him from keeping the field to the last. At the first restoration of the Bourbons he received the grand cross of the Legion of Honour and a command, and on the return of Napoleon from Elba he declined to join him until the king had fled from the country. He held a divisional command in the Waterloo campaign, and at Waterloo was again severely wounded at the head of his division (see Waterloo Campaign). After the second restoration he returned to civil life, devoting his energies for a time to his projected history of the Peninsular War, and in 1859 was elected to the chamber of deputies. For this position his experience and his studies had especially fitted him, and by his first speech he gained a commanding place in the chamber, which he never lost, his clear, manly eloquence being always employed on the side of the liberal principles of 1789. In 1845 he made a powerful protest against French intervention in Spain, and after the dissolution of 1824 he was re-elected for three constituencies. He died at Paris on the 28th of November 1825, and his funeral was attended, it is said, by 100,000 persons. His early death was regarded by all as a national calamity. His family was provided for by a general subscription.

The Histoire de la guerre de la Péninsule sous Napoléon was published from his notes in 1827, and a collection of his speeches (with memoir by Tissot) appeared in 1826 soon after his death. See Cuisin, Vie militaire, politique, etc., du général Foy; Vidal, Vie militaire et politique du général Foy.

FRAAS, KARL NIKOLAS (1830–1875), German botanist and agriculturalist, was born at Rattelsdorf, near Bamberg, on the 8th of September 1810. After receiving his preliminary education at the gymnasium of Bamberg, he in 1830 entered the university of Munich, where he took his doctor's degree in 1834. Having devoted great attention to the study of botany, he went to Athens in 1835 as inspector of the court garden; and in April 1836 he became professor of botany at the university. In 1842 he returned to Germany, and became first the central school at Schlesihn, in 1847 he was appointed professor of agriculture at Munich, and in 1851 director of the central veterinary college. For many years he was secretary of the Agricultural Society of Bavaria, but resigned in 1861. He died at his estate of Neufermann, near Munich, on the 9th of November 1875.

His principal works are: Erzgebirge (Berlin, 1833); Reisegeschichte der geographischen und plantagen in der Zeit (Landsh., 1847); Histor-encyklopädie, Grundriss der Landwirtschaftslehre (Stuttgart, 1848); Geschichte der Landwirtschaft (Frankf., 1851); Die Schule des Landesrates (Munich, 1852); Baierische Kinderrassen (Munich, 1853); Die künstliche Pflanzenzüchtung (Munich, 1854); Die Natur der Landwirtschaft (Munich, 1857); Buch der Natur für Landwirte (Munich, 1860); Die Ackerbaubücher von Carl Wilhelm Friedrich Richer (1798); Die Bewirtschaftung der Grainpfanzen (Berlin, 1872); and Geschichte der Landbau und Forstwissenschaft seit dem 16. Jahrh. (Munich, 1869). He also founded and edited a weekly agricultural paper, the Oberrane.

FRACASTORO, FRACASTORO, GIOVANNI BATTISTA (1483–1553), Italian physician and poet, was born at Verona in 1483. It is related of him that at his birth his lips adhered so closely that a surgeon was obliged to divide them with his incision knife, and that during his infancy his mother was killed by lightning, while he, though in her arms at the moment, escaped unhurt. Fracastoro became eminently skilled, not only in medicine and belles-lettres, but in all arts and sciences. He studied at Padua, and became professor of philosophy there in 1502, afterwards practising as a physician in Verona. It was by his advice that Pope Paul III., on account of the prevalence of a contagious disease, removed the council of the empire to the city.

He was the author of many works, both poetical and medical, and was intimately acquainted with Cardinal Beppo, Julius Scaliger, Gianbattista Ramusio, etc., and most of the great men of his time. In 1517, when the builders of the citadel of San Felice (Verona) found fossil mussels in the rocks, Fracastoro was consulted about the marvel, and he took the same view—following Leonardo da Vinci, but very advanced for those days—that they were the remains of animals once capable of living in the locality. He died of apoplexy at Cassi, near Verona, on the 8th of August 1553; and in 1559 the town of Verona erected a statue in his honour.

The principal work of Fracastoro is a kind of medical poem entitled Syphilisida, sive Morbi Gallici, libri tres (Verona, 1550), which has been often reprinted and also translated into French and Latin. Among his other works (all published at Venice) are De vini temperatura (1534); Homocentricorum (1535); De syphilis et anti palpia rerum (1535); and Contagionibus (1536). His complete works were published at Venice in 1555, and his poetical productions were collected and printed at Padua in 1728.

FRAGONARD, JEAN-HONORÉ (1732–1806), French painter, was born at Grasse, the son of a glover. He was articled to a Paris notary when his father's circumstances became straitened through unsuccessful speculations, but he showed such talent and inclination for art that he was taken at the age of eighteen to Boucher, who, recognizing the youth's rare gifts but dissuised his want of time with one so inexperienced, sent him to Chardin's atelier. Fragonard studied for six months under the great luminist, and then returned more fully equipped to Boucher, whose style he soon acquired so completely that the master entrusted him with the execution of replicas of his paintings. Though not a pupil of the Academy, Fragonard gained the Prix de Rome in 1752 with a painting of "Jeroobam sacrificing to the Idols," but before proceeding to Rome he continued to study for three years under Van Loo. In the year preceding his departure he painted the "Christ washing the Feet of the Apostles," now at Grasse cathedral. In 1755 he took up his abode at the French Academy in Rome, then presided over by Natoire. There he
benefited from the study of the old masters whom he was set to copy—always remembering Boucher's parting advice not to take Raphael and Michelangelo too seriously. He successively passed through the studios of masters as widely different in their aims and technique as Chardin, Boucher, Van Loo and Natoire, and a summer sojourn at the Villa d'Este in the company of the abbé de Saint-Non, who engraved many of Fragonard's studies of these entrancing gardens, did more towards forming his personal style than all the training at the various schools. It was in these romantic gardens, with their fountains, grottos, temples and terraces, that he discovered the Chinese and Japanese, and he decided definitely to base those scenes of love and voluptuousness with which his name will ever be associated, and which are only made acceptable by the tender beauty of his colour and the virtuosity of his facile brushwork—such works as the "Serment d'amour" (Love Vow), "Le Verrou" (The Bolt), "La Culbute" (The Tumble), "La Chemise célévée" (The Shift Withdrawn), and "The Swing" (Wallace collection), and his decorations for the apartments of Mme du Barry and the dancer Marie Guimard.

The Revolution made an end to the ancien régime, and Fragonard, who was so closely allied to its representatives, left Paris in 1792 and found shelter in the house of his friend Mme de Grasse, where he decorated the series of decorative panels known as the "Roman d'amour de la jeunesse," originally painted for Mme du Barry's pavilion at Louveciennes.

The panels in recent years came into the possession of Mr Pierpont Morgan. Fragonard returned to Paris early in the 19th century, where he died in 1806, neglected and almost forgotten. For half a century or more he was so completely ignored that Lübke, in his history of art (1873), omits the very mention of his name. But within the last thirty years he has regained the position which he occupied in the 18th century, and his compositions have been studied with the care due to the genius. If the appreciation of his art by the modern collector can be expressed in figures, it is significant that the small and sketchy "Billet Doux," which appeared at the Cronier sale in Paris in 1905 and was subsequently exhibited by Messrs Duveen in London (1906), realized close on £50,000 at the Hôtel Drouot.

Besides the works already mentioned, there are four important pictures by Fragonard in the Wallace collection: "The Fountain of Love," "The Schoolmistress," "A Lady carving her Name on a Tree" (usually known as "Le Chiffre d'amour") and "The Fair-haired Child." The Louvre contains thirteen examples of his art, among them the "Corésus," "The Sleeping Bacchanter," "The Shift Withdrawn," "The Bathers," "The Shepherd's Hour" ("L'Heure du berger"), and "Inspiration." Other works are in the museums of Lille, Besançon, Rouen, Tours, Nantes, Avignon, Amiens, Grenoble, Nancy, Orleans, Marseilles, &c., as well as at Chantilly. Some of Fragonard's finest work is in the private collections of the Rothschild family in London and Paris.

FRAHN, CHRISTIAN MARTIN (1782-1851), German numismatist and historian, was born at Rostock. He began his Oriental studies under Tychsen at the university of Rostock, and afterwards prosecuted them at Göttingen and Tübingen. He became a Latin master in Pestalozzi's famous university in 1804, returned home in 1806, and in the following year was chosen to fill the chair of Oriental languages in the Russian university of Kazan. Though in 1815 he was invited to succeed Tychsen at Rostock, he preferred to go to St Petersburg, where he became director of the Asiatic museum and counsellor of state. He died at St Petersburg. Fragonard wrote over 190 works. Among the more important are: Numismathicum orientale Polonicae (1813); De numeris Bulgariorum antiquissima (1816); Der Kaiserlich-russische und Kaiserlich-deutschen archäologische und numismatische Kabinett des asiatischen Museum der kaiserl. Akademie der Wissenschaften zu St Petersburg (1821); Num mi cufci ex variis museis selecti (1823); Notiz einer centen a d'ouvrages graces; &c., qu'entraînent en grande partie aux bibliothèques de l'Europe (1834); and Nova supplementa ad recensionem Num. Mh. Acad. Imp. Sci. Petropolitanae (1855). His description of some medals struck by the Samanids and Boulid princes (1804) was composed in Arabic because he had no Latin types. 

FRAME, a word employed in many different senses, signifying something joined together or shaped. It is derived ultimately from O.E. fram, from, in its primary meaning "forward." In constructional work it connotes the union of pieces of wood, metal or other material for purposes of enclosure as in the case of a picture or mirror frame. Frames intended for these uses are of great artistic interest but comparatively modern origin. There is no record of their existence earlier than the 16th century, but the decorative arts of that period which they afforded speedy popularity in an artistic age, and the Renaissance found in the picture frame a rich and attractive means of expression. The impulses which made frames beautiful have long been extinct or dormant, but fine work was produced in such profusion that great numbers of examples are still extant. Frames for pictures or mirrors are usually square, oblong, round or oval, and, although they have usually been made of wood or composition overlaid upon wood, the richest and most costly materials have often been used. Ebony, ivory and tortoiseshell; crystal, amber and mother-of-pearl; lacquer, gold and silver, and every other metal have been employed for this purpose. The domestic frame has in fact varied from the simplest and cheapest form of a plain wooden moulding to the most richly carved examples. The introduction in the 17th century of larger sheets of glass gave the art of frame-making a great essor, and in the 18th century the increased demand for frames, caused chiefly by the introduction of cheaper forms of mirrors, led to the invention of a composition which could be readily moulded into stereotyped patterns and gilded. This was eventually the deathblow of the artistic frame, and since the adoption of gilding, the decoration of the frame has been left to the wood-carver. The school of wood-carving has turned its attention to frames. The carvers of the Renaissance, and down to the middle of the 18th century, produced work which was often of the greatest beauty and elegance. In England nothing comparable to that of Grinling Gibbons and his school has since been produced. Chippendale was a great frame maker, but he not only had recourse to composition, but his designs were often extravagantly rococo. Even in France there has been no return of the great days when Oeben enclosed the looking-glasses which mirrored the Pompadour in frames that were among the choicest work of a gorgeous and artificial age. In the decoration of frames as in so many other respects France largely followed the fashions of Italy, which throughout the 16th and 17th centuries produced the most elaborate and grandiose, the richest and most palatial, of the mirror frames that have come down to us. English art in this respect was less exotic and more restrained, and many of the mirrors of the 18th century received frames the grace and simplicity of which have ensured their constant reproduction even to our own day.

FRAMINGHAM, a township of Middlesex county, Massachusetts, U.S.A., having an area of 27 sq. m. of hilly surface, dotted with lakes and ponds. Pop. (1890) 9230; (1900) 11,302, of whom 2301 were foreign-born; (1910 census) 12,948. It is served by the Boston & Albany, and the New York, New Haven & Hartford railways. Included within the township are three villages, Framingham Center, Saxonville and South Framingham, the last being much the most important. Framingham Academy was established in 1792, and in 1851 became a part of the public school system. A state normal school (the first normal school in the United States, established at Lexington
in 1839, removed to Newton in 1844 and to Framingham in 1853) is situated here and near South Framingham, in the township of Sherborn, is the state reformatory prison for women. South Framingham has large manufactories of paper tags, shoes, boilers, carriage wheels and leather board; formerly straw braid and bonnets were the principal manufactures. Saxonville manufactures worsted cloth. The value of the township's factory products increased from $3,007,301 in 1900 to $4,173,579 in 1905, or 38.8%. Framingham was first settled about 1640, and was named in honour of the English home (Framingham) of Governor Thomas Danforth (1622-1699), to whom the land once belonged. The town was incorporated in 1639. The "old Connecticut path," the Boston-to-Worcester turnpike, was important to the early fortunes of Framingham Center, while the Boston & Worcester railway (1834) made the greater fortune of South Framingham.

See J. H. Temple, History of Framingham . . . 1640-1880 (Framingham, 1887).

**FRAMINGHAM,** a market town in the Eye parliamentary division of Suffolk, 91 m. N.E. from London by a branch of the Great Eastern railway. For Pottery the St Albans and North Midland line Perpendicular and Decorated building of black dirt, surmounted by a tower 66 ft. high. In the interior there are a number of interesting monuments, among which the most noticeable are those of Thomas Howard, 3rd duke of Norfolk, and of Henry Howard, the famous earl of Surrey, who was beheaded by Henry VIII. The castle forms a picturesque ruin, consisting of the outer walls 44 ft. high and 8 ft. thick, 13 towers about 58 ft. high, a gateway and some outworks. About half a mile from the town is the Albert Memorial Middle Class College, opened in 1865, and capable of accommodating 300 boys. A bronze statue of the Prince Consort by Joseph Durham adorns the front terrace.

Framingham (Frendlingham, Framinghgham) in early Saxon times was probably the site of a fortified earthwork to which St Edmund the Martyr is said to have fled from the Danes in 870. The Danes captured the stronghold after the escape of the king, but it was won back in 921, and remained in the hands of the crown, passing to William I. at the Conquest. Henry I. in 1100 granted it to Roger Bigod, who in all probability raised the first masonry castle. Hugh, son of Roger, created earl of Norfolk in 1111, succeeded his father, and the manor and castle remained in the Bigod family until 1306, when in default of heirs it reverted to the crown, and was granted by Edward II. to his half-brother Thomas de Brotherton, created earl of Norfolk in 1312. On an account roll of Framingham Castle of 1344 there is an entry of "rent received from the borough," also of "rent from those living outside the borough," and in all probability burghal rights had existed at a much earlier date, when the town had grown into some importance under the shelter of the castle. Town and castle followed the vicissitudes of the dukedom of Norfolk, passing to the crown in 1265, and being alternately restored and forfeited by Henry V., Richard III., Henry VII., Edward VI., Mary, Elizabeth and James I., and finally sold in 1635 to Sir Robert Hitcham, who left it in 1656 to the master and fellows of Pembroke Hall, Cambridge.

In the account roll above mentioned reference is made to a fair and a market, but no early grant of either is to be found. In 1792 two annual fairs were held, one on Whit Monday, the other on the 10th of October; and a market was held every Saturday. The market day is still Saturday, but the fairs are discontinued.

See Robert Hawes, History of Framingham in the County of Suffolk, edited by R. Loder (Woodbridge, 1798).

**FRANC, a French coin current at different periods and of varying values. The first coin so called was one struck in gold by John II. of France in 1360. On it was the legend Johannes Francorum regis, hence, it is said, the name. It also bore an effigy of King John on horseback, from which it was called a franc à chéval, to distinguish it from another coin of the same value, issued by Charles V., on which the king was represented standing upright under a Gothic dais; this coin was termed a franc à pied. As a coin it disappeared after the reign of Charles VI., but the name continued to be used as an equivalent for the livre tournois, which was worth twenty sols. French writers would speak without distinction of so many livres or so many francs, so long as the sum mentioned was an even sum; otherwise livre was the correct term, thus "trois livres" or "trois francs," but "trois livres cinq sols." In 1795 the livre was legally converted into the franc, at the rate of 81 livres to 80 francs, the silver franc being made to weigh exactly five grammes. The franc is now the unit of the monetary system and is used in France, as well as in Belgium and Switzerland. In Italy the equivalent is the lira, and in Greece the drachma. The franc is divided into 100 centimes, the lira into 100 centesimi and the drachma into 100 lepta. Gold is now the standard, the coins in common use being ten and twenty franc pieces. The twenty franc gold piece weighs 6.156 grammes, .900 fine. The silver coins are five, two, one, and half franc pieces. The five franc silver piece weighs 23 grammes, .900 fine, while the franc piece weighs 5 grammes, .85 fine. See also MÉTIER, ATOMIC, COIN.

**FRANC AIS, ARCHDUKE COUNT (1726-1836), better known as FRANÇAIS OF NANTES, French politician and author, was born at Beaugrepaire, in the department of Isère. In 1791 he was elected to the legislative assembly by the department of Loire Inferieure, and was noted for his violent attacks upon the farmers general, the pope and the priests; but he was not re-elected to the Convention. During the Terror, as he had belonged to the Girondin party, he was obliged to seek safety in the mountains. In 1798 he was elected to the council of Five Hundred by the department of Isère, and became one of its secretaries; and in the following year he voted against the Directory. But took office under the consulate as prefect of Charente Inferieure, rose to be a member of the council of state, and in 1804 obtained the important post of director-general of the indirect taxes (droits réunis). The value of his services was recognized by the titles of count of the empire and grand officer of the Legion of Honour. On the second restoration he retired into private life; but from 1819 to 1822 he was representative of the department of Isère, and after the July revolution he was made a peer of France. He died at Paris on the 7th of March 1836.

Français, François Louis (1814-1897), French painter, was born at Plombières (Vosges), and, on attaining the age of fifteen, was placed as office-boy with a bookseller. After a few years of hard struggle, during which he made a precocious living by drawing on stone and designing woodcut vignettes for book illustration, he studied painting under Gignoux, and subsequently under Corot, whose influence remained decisive upon Français' style of landscape painting. He generally found his subjects in the neighbourhood of Paris, and though he never rivalled his master in lightness of touch and in the lyric poetry which is the principal charm of Corot's work, he is still counted among the leading landscape painters of his country and period. He exhibited first at the Salon in 1837 and was elected to the Académie des Beaux-Arts in 1860. Comparatively few of his pictures are to be found in public galleries, but his painting of "An Italian Sunset" is at the Luxembourg Museum in Paris. Other works of importance are "Daphnis et Chloé" (1872), "Bas Meudon" (1861), "Orphée" (1863), "Le Bois sacré" (1864), "Le Lac de Nemi" (1868).

**FRANCATELLI, CHARLES ELMÉ (1805-1870), Anglo-Italian cook, was born in London, of Italian extraction, in 1805, and was educated in France, where he studied the art of cookery. Coming to England, he was employed successively by various noblemen, subsequently becoming manager of Crockett's club. He left Crockett's to become chief cook to Queen Victoria, and afterwards he was chef at the Reform Club. He was the
FRANÇAVILLA FONTANA—FRANCE

Lightly as he bears his erudition, it is very real and extensive, and is notably shown in his utilization of modern archaeological and historical research in his fiction (as in the stories in *Sur une pierre bleue*). As a critic—see *Le Vie littéraire* (1888-1892), reprinted mainly from *Le Temps*—he is graceful and appreciative.

Academic in the best sense, he found a place in the French Academy, taking the seat vacated by Lesseps, and was received into that body on the 24th of December 1896. In the *affaire Dreyfus* he sided with M. Zola.

FRANCE, a country of western Europe, situated between 4° 54' and 49° 20' N., and 2° 42' W. and 7° 36' E. It is hexagonal in form, being bounded N.W. by the North Sea, the Strait of Dover (*Pas de Calais*) and the English Channel (*La Manche*), W. by the Atlantic Ocean, S.W. by Spain, S.E. by the Mediterranean Sea, E. by Italy, Switzerland and Germany, N.E. by Germany, Luxemburg and Belgium. From north to south its length is about 600 m., measured from Dunkirk to the Col de Falguières; its breadth from east to west is 538 m., from the Vosges to Cape Sizun. If the massif of the Pyrenees, however, be taken at the Pyrenean crest, the total area is estimated 1 at 207,170 sq. m., including the island of Corsica, which comprises 3,567 sq. m. The coast-line of France extends for 3,843 m. on the Mediterranean, 700 on the North Sea, the Strait of Dover and the Channel, and 863 on the Atlantic. The country has the advantage of being separated from its neighbours over the greater part of its frontier by natural barriers of great strength, the Pyrenees forming a powerful bulwark on the south-west, the Alps on the south-east, and the Jura and the greater portion of the Vosges Mountains on the east. The frontier generally follows the great line of the Pyrenees, the Vosges, the Rhine and the Rhone, between which the Pyrenean system is divided by the Rhone: a river which, rising in the Swiss canton of Valais, and flowing westwards for 533 m. through the Graie valley, is a border stream to the Austrian empire on the upper course, and to the empire of France on the lower.

France is geographically remarkable for its possession of great natural and historical highways between the Mediterranean and the Atlantic Ocean. The one, following the depression between the central plateau and the eastern mountains by way of the valleys of the Rhône and Saône, traverses the Côte d'Or hills and so gains the valley of the Seine; the other, skirting the southern base of the Cévennes, reaches the ocean by way of the Durance and the valley of the Rhône. The latter route, which passes through the Rhone valley, from the Rhone's mouth to the point of the north-east boundary, is conventional and unsurpassed by nature.

France is geographically remarkable for its possession of great natural and historical highways between the Mediterranean and the Atlantic Ocean. The one, following the depression between the central plateau and the eastern mountains by way of the valleys of the Rhône and Saône, traverses the Côte d'Or hills and so gains the valley of the Seine; the other, skirting the southern base of the Cévennes, reaches the ocean by way of the Durance and the valley of the Rhône. The latter route, which passes through the Rhone valley, from the Rhone's mouth to the point of the north-east boundary, is conventional and unsurpassed by nature.

Physiography.—A line drawn from Bayonne through Agen, Poitiers, Troyes, Reims and Valenciennes divides the country roughly into two dissimilar physical regions—the west and north-west a country of plains and low plateaus; in the centre, east and south-east a country of mountains and high plateaus with a minimum elevation of 650 ft. To the west of this line the highlands of importance are the granitic plateaus of Brittany and the hills of Normandy and Perche, which, uniting with the plateau of Beauce, separate the basins of the Seine and Loire. The highest elevations of these ranges do not exceed 1400 ft. The highest point of the mountainous east of the dividing line is the Mont Dôme. Its most striking feature is the mountainous and eruptive area known as the Massif Central, which covers south-central France. The central point of this huge tract is formed by the mountains of Auvergne comprising the group of Cantal, where the Pomb of the Cantal attains 6096 ft., and that of Mont Dore, containing the Puy de Sancy (6188 ft.), the culminating point of the Massif, and to the north the lesser elevations of the Monts Dôme. On the west downward slope is gradual by way of lofty plateaus to the heights of Limousin and Marche and the table-land of Quercy, thence to the plains of Poitou, Angoumois and Guienne. On the east only the higher plateaus divide the valley of the Rhône from the Pyrenean system by the river Aude. On the south-western border of France the Pyrenees include

---

1 By the *Service géographique de l'armée*.
several peaks over 10,000 ft. within French territory: the highest elevation therein, the Vignemale, in the centre of the range, reaches 10,820 ft. On the north their most noteworthy offshoots are, in the centre, the plateau of Langnemeau from which rivers radiate fanwise to join the Adour and Garonne; and in the east the Courbierre. On the south-eastern frontier the French Alps, which include Mont Blanc (15,800 ft), and, more to the south, other summits over 11,000 ft. in height, cover Savoy and most of Dauphiné and Provençal, that is to say, nearly the whole of France to the south and east of the Rhône. North of that river the parallel chains of the Jura form an arc of a circle with its convexity towards the north-west. In the southern and most elevated portion of the range there are several summits exceeding 5500 ft. Separated from the Jura by the defile of Belfort (Trouée de Belfort) the Vosges extend northward parallel to the course of the Rhône. Their culminating points in French territory, the Ballon d’Alsace and the Hohneck in the southern portion of the chain, reach 4100 ft. and 4480 ft. The Vosges are buttressed on the west by the Faucilles, which curve southwards to meet the plateau of Langres, and by the plateaus of Haute-Marne, united to the Ardennes on the north-eastern frontier by the wooded highlands of Argonne.

Seaward.—The shore of the Mediterranean encircling the Gulf of the Lion (Golfe du Lion) from Cape Carbonera to Martigues is lowlying and unbroken, and characterized chiefly by bays separated from the sea by sand-dunes. The coast, constantly encroaching on the sea by reason of the alluvium washed down by the rivers of the Pyrenees and Cévennes, is without important harbours save that of Céret, itself continually invaded by the sand. East of Martigues the coast is rocky and of greater altitude, and is broken by projecting capes (Couronne, Croisette, Sicé, the peninsula of Giens and Cape Antilles), and by deep gulls forming secure roadsteads such as those of Marseilles, which has the chief port in France, Toulon, with its great naval harbour, and Hyères, to which may be added the Gulf of St. Tropez.

Along the Atlantic coast from the mouth of the Adour to the

1 The etymology of this name (sometimes wrongly written Golfe de Lyon) is unknown.
estuary of the Gironde there stretches a monotonous line of sand-dunes bordered by lagoons on the land side, but towards the sea harbourless and unbroken save for the Bay of Arcachon. To the north as far as the rocky point of St Gilles, sheltering the mouth of the Gironde, wild and unbroken portions of the coast, fringed with sand-dunes, the chief of which is the Sèvre Niortaise, drain the coast region to the south of the plateau of Gâtine.

France is a country of over 47,000 sq. m., includes a great part of central and western France or nearly a quarter of the whole country. The Loire rises in Mont Gerbier de Jonc, in the range of the Vivarais mountains, flows due north to the Loire-sur-Cher, thence north-west to Tours and Chartres, and descends by the Seine into the English Channel below Caen, from which it was separated by the Sèvre Niortaise and the Bay of Biscay, and through which the Channel is periodically barred by sandbanks. The estuary of the Gironde, the chief of which is the Sèvre Niortaise, drain the coast region to the south of the plateau of Gâtine.

North of the basin of the Gironde an area of over 3600 sq. m. is watered by the secondary system of the Charente, which descends from Chéronnac (Haute-Vienne), traverses Angoulême and falls into the Atlantic at Noirmoutier. The river, the chief of which is the Sèvre Niortaise, drain the coast region to the south of the plateau of Gâtine.

The basin of the Loire, with an area of about 47,000 sq. m., includes a great part of central and western France or nearly a quarter of the whole country.
